Results: DGF rate was 21.7% for DBD cases, whereas it was around 40% for DCD cases with HWIT shorter than 30 min (0-10 min: 42.1%, 11-20 min: 43%, 21-30 min: 38.4%) and it was 60% for DCD cases with HWIT longer than 30 min (p<0.001). All DCD groups showed higher DGF risk when compared with DBD renal transplants in logistic regression analysis also (0-10 min: OR=2.686, 95%CI: 2.352-3.068, p<0.001, 11-20 min: OR=2.531, 95%CI: 2.003-3.198, p<0.001, 21-30 min: OR=1.764, 95%CI: 1.017-3.059, p=0.043, >30 min: OR=5.814, 95%CI: 2.798-12.081, p<0.001). The highest risk for DGF in DCD renal transplants with HWIT more than 30 min was again confirmed by logistic regression analysis when it was compared with that of the other groups (compared with DBD: OR=5.814, 95%CI: 2.798-12.081, p<0.001; compared with DCD: 0-10 min: OR=2.165, 95%CI: 1.038-4.505, p=0.039; 11-20 min: OR=2.299, 95%CI: 1.075-4.902, p=0.032; 21-30 min: OR=3.3, 95%CI: 1.33-8.197, p=0.01). No statistically significant differences were detected regarding PNF rates (p=0.713) or graft survival (p=0.757), which was confirmed by multivariate analysis.

Conclusions: HWIT of more than 30 min increases the risk for DGF greatly, but without affecting the possibility of PNF or the graft survival.

Abstract# 848

The Implications of Donor-Recipient Size Mismatch in Renal Transplantation

I. D. Kostakis, N. Karydis, T. Kassimatis, N. Kessaris, I. Loukopoulos, *Department of Transplantation, Guy's Hospital, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*

Purpose: Transplanting kidneys small for the recipient's size results in inferior renal graft function. Body surface area (BSA) is related to kidney size. We used the BSA index (BSAi) (Donor BSA/Recipient BSA) to assess whether the renal parenchymal mass provided by the donor is sufficient for the recipient.
Methods: We included 26223 adult single kidney-only transplants (01/01/2007-31/12/2019) from the UK Transplant Registry. We divided renal transplants in groups: BSAi≤0.75, 0.75<BSA≤1, 1<BSAi≤1.25, BSAi>1.25. We compared delayed graft function (DGF) rates, primary non-function (PNF) rates and graft survival among them in the entire cohort and for each donor type separately [living, donation after brain death (DBD), donation after circulatory death (DCD)] (reference category: BSAi≤0.75).
Results: Cases with BSAi≤0.75 had the highest DGF rates in living-donor renal transplants (11.1%) (0.75<BSAi≤1: OR=0.591, 95%CI: 0.318-1.097, p=0.095, 1<BSAi≤1.25: OR=0.456, 95%CI: 0.232-0.894, p=0.022, BSAi>1.25: OR=0.318, 95%CI: 0.132-0.766, p=0.011) and DBD renal transplants (26.2%) (0.75<BSAi≤1: OR=0.723, 95%CI: 0.546-0.957, p=0.024, 1<BSAi≤1.25: OR=0.621, 95%CI: 0.465-0.83, p=0.001, BSAi>1.25: OR=0.65, 95%CI: 0.468-0.903, p=0.01). There were no significant differences in DCD renal transplants regarding DGF rates (just above 40% in all groups). No significant differences were found concerning PNF. Graft survival was similar among BSAi groups in living-donor and DBD renal transplants. DCD renal transplants with BSAi≤0.75 had shorter graft survival than the other groups (0.75<BSAi≤1: HR=0.548, 95%CI: 0.408-0.736, p<0.001, 1<BSAi≤1.25: HR=0.48, 95%CI: 0.352-0.655, p<0.001, BSAi>1.25: HR=0.45, 95%CI: 0.307-0.66, p<0.001). 5-year and 10-year graft survival rates were 73% and 58%, respectively, for DCD renal transplants with BSAi≤0.75.
Conclusions: DGF risk is higher in living-donor and DBD renal transplants with BSAi≤0.75. Graft survival is greatly reduced in DCD renal transplants with BSAi≤0.75.

Abstract# 849

Trends in the Recovery and Discard of Kidneys from Deceased Donors with Acute Kidney Injury from 2010-2018

C. Liu[1], S. Alasfar[2], P. P. Reese[3], S. Mohan[4], M. D. Doshi[5], I. E. Hall[6], H. R. Thiessen-Philbrook[2], Y. Jia[2], D. E. Stewart[7], C. Parikh[2], *[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Perelman School of Medicine, Philadelphia, PA, [4]New York-Presbyterian/Columbia University Irving Medical Center, New York, NY, [5]University of Michigan, Ann Arbor, MI, [6]University of Utah School of Medicine, Salt Lake City, UT, [7]United Network for Organ Sharing, Richmond, VA*

Purpose: Since the donor KDPI score used in KAS is restricted to a single terminal serum creatinine (SCr) measurement, kidneys from donors with transient acute kidney jury (AKI) may have misleadingly high KDPI scores. We characterized trends in the recovery and discard of kidneys from deceased donors with AKI in the context of KAS implementation.
Methods: We retrospectively analyzed 71,180 donors in the OPTN database >16 years of age who had at least one organ recovered for transplant between 1/1/2010-1/1/2019. AKI was defined as ≥50% or ≥0.3 mg/dL increase in terminal SCr from admission. AKI stages were defined by KDIGO guidelines. The primary outcomes were kidney recovery and discard rates. We estimated the change in discard rate following KAS implementation (in 12/2014) with interrupted time series adjusted for secular trends.
Results: Of 130,506 kidneys recovered, 25,982 (20%) were not utilized, half (12,780) of which were from donors with AKI. The proportion of donors with any AKI did not change significantly (~38%) during this time frame. The proportion of donors with stage 3 AKI increased from 6% (412/6841 donors) in 2010 to 11% (1056/9575 donors) in 2018. The kidney recovery rate did not change significantly from 2010-2018 among lower stages of AKI. The recovery rate of kidneys from donors with stage 3 AKI kidneys increased from 51% (423/824 kidneys) in 2010 to 62% (1488/2112 kidneys) in 2018. Discard of recovered stage 3 AKI kidneys decreased from 41% (175/423 kidneys) in 2010 to 32% (153/481 kidneys) in 2012 but increased after KAS implementation by 7% and remained high at 42% (619/1488 kidneys) in 2018 (**Figure**). The number of centers transplanting >5% stage 3 AKI kidneys increased from 6% (32/493) in 2010 to 15% (75/493) in 2018.
Conclusions: KAS may have contributed to the increased discard rate of stage 3 AKI kidneys. Concurrent increases in discard and transplantation of stage 3 AKI kidneys suggest increasing recovery that outpaces transplantation.

Abstract# 850

Two-for-One Kidney Transplant Outcomes

C. Malanga[1], H. Madeem[2], K. Robichaux[2], J. Buggs[3], A. Kumar[1], V. Bowers[3], *[1]Morsani College of Medicine, University of South Florida, Tampa, FL, [2]Honors College, University of South Florida, Tampa, FL, [3]Transplant Surgery, Tampa General Hospital, Tampa, FL*

Purpose: In the United States, over 91,000 people are on the waiting list for a kidney transplant. Concurrently, 3,500 kidneys deemed to be of marginal quality are discarded per year. "Two-for-One" kidney transplants use two marginal kidneys for a single recipient to provide adequate nephron mass. The purpose of this study was to evaluate outcomes with Two-for-One kidney transplants performed nationally compared with outcomes at a single center.
Methods: We conducted a retrospective cohort study of all consecutive adult kidney transplants performed from January 2012 to April 2020. National data and our local center data were analyzed separately. We compared outcomes in single kidney transplants (KT) compared with two-for-one KT in both data sets. National data was obtained from the United Network for Organ Sharing (UNOS) and our local center data was collected from the electronic medical records.
Results: Nationally there were 248,755 kidney transplants with 2,501 (1%) two-for-one KT. Our center performed 1,455 kidney transplants with 38 (2.6%) two-for-one KT during the study period. The mean national donor age was 38 vs. 57 years for single KT and two-for-one KT respectively, (p<0.001) compared with a mean age of 19 vs.38 years at our local center (p<0.001). The national recipient mean age was 50 vs.59 years for single KT and two-for-one KT respectively, (p<0.001) compared with our local center recipient mean age of 33 vs. 58 years (p<0.001). Nationally, there was a statistical difference in delayed graft function between the single KT (25%) compared with two-for-one KT (30%), p<0.001. There was no difference in delayed graft function between the two groups at our center, single KT (17%) vs. two-for-one KT (18%), p=1.00. Nationally, single KT had better graft survival than two-for-one KT (p<0.001), while there was no difference at our center, p=0.32. Patient survival at the national level was significantly improved for single KT vs. two-for-one KT (p<0.001), whereas there was no difference in patient survival in our center's data (p=0.82).

Conclusions: Two-for-one kidney transplants are a viable means of expanding the organ donor pool, however patient and graft survival differ between the national and local center data. These findings suggest disparities between both the quality of organs and recipient selections. Further studies of donor and recipient comorbidities and risk factors are warranted to facilitate greater utilization of two-for-one kidney transplants.

Abstract# 851

Transplant Center Volume in High-risk Donors are Associated with Graft and Patient Survival

M. A. Merzkani, H. Murad, M. Mattu, M. Wang, V. Hu, S. Chang, T. Alhamad, *Transplant, Washington University, Saint Louis, MO*

Purpose: Evaluation of high-risk kidney donors in transplant centers involves an intensive assessment of the individual risks and selection of appropriate recipients. Understandably, this requires well thought out protocols and structures to maintain good outcomes. In this study, we explore the association of center volume with patient and graft survival in high risk donor transplants.

Methods: We reviewed Organ Procurement and Transplantation Network (OPTN) data on kidney transplants among 285 transplant centers between 2000 and 2016. High-risk kidney transplant included donation after cardiac death (DCD), cold ischemic time≥24 hours and high KDPI≥85%. For each high-risk transplant, transplant centers were categorized into tertiles of low, medium and high volume according to the annual average transplant volume of such transplant. The outcomes were death censored graft loss (DCGL) and death with functioning graft (DWFG). The association of center volume with each outcome was analyzed using multivariable Cox regression including adjustment for recipient, donor, and transplant characteristics.

Results: Compared to high volume centers, the lower and medium center volume for DCD kidneys had a lower risk for DCGL at 3 months (aHR=0.771[0.639-0.932]; aHR=0.733[0.605-0.888]) longer follow up at 1, 5 and 10 years and overall have similar trends. There was only lower risk for DWFG for medium center volume DCD in 10 years aHR=0.910(0.844-0.982) and overall aHR=0.912 (0.848-0.981). For lower volume and medium volume with cold ischemic time ≥ 24 hours there was lower risk for DCGL at 1 year (aHR=0.869[0.778-0.971];aHR=0.889[0.799-0.989]), 5 years (aHR=0.892[0.831-0.957];aHR=0.918[0.858-0.982]); 10 years (aHR=0.925[0.871-0.982];aHR=0.935[0.882-0.990]) and overall (aHR=0.933[0.882];aHR=0.930[0.880-0.983]) when compare high center volume. In low and medium center volumes for prolonged cold ischemic time there was a lower risk for DWFG overall (aHR= 0.940[0.897-0.986]; aHR=0.933[0.892-0.980]) when compared with high center volume. We observed that lower and medium center volume in kidney with a KDPI≥85% were not associated with higher risk for DCGL and DWFG.

Conclusions: We found that DCD and cold ischemic time≥24 hour had a worse DCGL in high volume centers but not in kidney with high KDPI≥ 85%. Large studies with prospective follow up are needed to determine donor characteristics of DCD and cold ischemic time>24 hours that lead to greater risk for DCGL in high volume centers.

Abstract# 852

Improving Eligibility of Renal Transplants in the Elderly

L. B. Moraitis, J. Rogers, A. Farney, A. Reeves-Daniel, G. Orlando, W. Doares, S. Kaczmorski, A. Mena-Gutierrez, C. Jay, R. Stratta, *Abdominal Organ Transplant, Wake Forest Baptist Health, Winston-Salem, NC*

Purpose: In the recent past, older age was contraindication to kidney transplantation (KT). New kidney allocation schemes with use of longevity matching, initiation of frailty testing, and enhanced psychosocial assessment have improved kidney access for the elderly population, age 75 and higher.

Methods: We retrospectively reviewed outcomes in adult patients (pts) ≥75 years of age transplanted at our center with kidneys from deceased donors. All patients (pts) received antibody induction in combination with reduced dose FK, MMF, and steroids. Protocol adjustments included frailty testing, stricter psychosocial clearance, and demonstration of stable comorbidities.

Results: Over a 16-year period, we performed 92 KTs (4.7% of all adult KTs) in pts age ≥75 (mean 77 years, range 75-84). The recipient group included 40 women and 52 men (58 white, 31 black, 3 other) with a mean waiting time of 13 months and dialysis

duration of 30 months. 11 pts (12%) were transplanted prior to starting dialysis. 55 pts (60%) received kidneys from expanded criteria donors (ECDs, including 25 ≥ age 65), 8 pts received dual kidney transplants, and 6 were retransplants. Mean KDPI was 74%. The incidence of delayed graft function (need for dialysis post-KT) was 23%. With a mean follow-up of 53 months (60 pts had at least 5 years f/u), actual pt and kidney graft survival rates were 57% and 49%, respectively; death-censored kidney graft survival (DCGS) was 70%. One year pt and kidney graft survival rates were 95% and 88%, respectively. Of 47 graft losses, 11 occurred within 1 year and 28 (60%) were secondary to death with a functioning graft (DWFG). Half of the deaths and DWFGs occurred ≥ 5 years post-KT. At present, 45 of the 52 surviving pts (87%) have functioning grafts. Major causes of death were cardiovascular (10), stroke (7), sepsis (6), and respiratory failure (6). The incidences of surgical complications, acute rejection and major infection were 9%, 20%, and 25%, respectively. In 28 cases, the mate kidney from the same donor was transplanted into a <75 year old pt (mean age 60 years) at our center. DCGS rates in the donor-matched pairs were comparable in the older (56%) and younger (59%) age cohorts.

Conclusions: New kidney allocation policies should not discriminate against older recipients who are physically active and functional, have good psychosocial support, and have stable comorbidities. Acceptable medium-term outcomes can be achieved in appropriately selected elderly patients, improving both their quality and quantity of life compared to dialysis. By using predominantly ECD kidneys, which otherwise may not be appropriate for younger patients, we have enhanced opportunities for KT in the elderly while simultaneously reducing the risk for organ discard, thus permitting liberalization of both donor and recipient eligibility criteria.

Abstract# 853

Outcomes in Older Recipients Receiving Kidneys from Donors with Acute Kidney Injury (AKI)

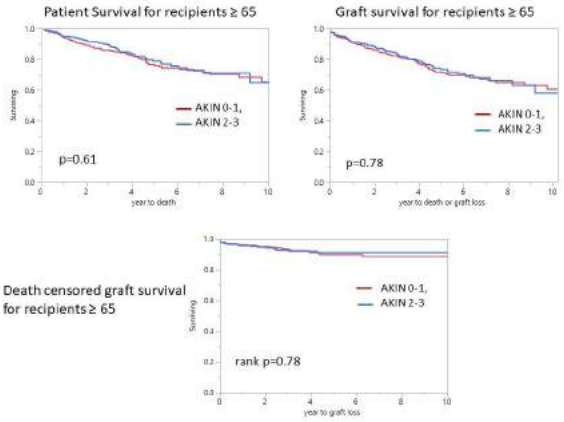
S. Nair, K. Reddy, L. Kodali, P. Budhiraja, J. Ninan, C. Jadlowiec, A. Mathur, J. Harbell, H. Khamash, M. Smith, R. Heilman, *Mayo Clinic, Phoenix, AZ*

Purpose: Older patients are perceived to tolerate delayed graft function (DGF) poorly and there is a reluctance to transplant a kidney from an AKI donor into older recipients. Our aim was to examine the outcomes of older transplant recipients (age ≥65years) receiving kidneys from donors with AKI.

Methods: We included all patients ≥65 years of age who received deceased donor kidney transplants from 2/1/08 - 12/29/19 at our center. We used acute kidney injury network (AKIN) criteria to assess the severity of AKI in the donors. Patients who received kidneys from donors with AKIN2-3 were compared to those receiving kidneys from AKIN0-1 donors. The primary outcomes were patient survival, all-cause and death-censored graft survival.

Results: Of the 594 patients who received kidney transplant at our center during the study period 265 received AKIN 2-3 kidneys and 329 received AKIN 0-1 kidneys. Baseline characteristics were similar between the 2 groups. AKIN 2-3 had a lower KDPI (58 Vs 68), younger donor age (43 Vs 51) and lower % of DCD kidneys (12 VS 23%). DGF rate was higher in the AKIN 2-3 group (65% vs 45%). The patient survival, graft survival, death censored graft survival, 1 year GFR and rejection rate were not significantly different. Biopsies at 1 year showed no significant difference for acute or chronic changes (table 2). Death with functioning graft was the most common cause for graft failure in both groups (67.4% AKIN0-1 Vs 69.8% AKIN2-3). 4 cases of primary non function (PNF) were seen in AKIN0-1 Vs 3 in AKIN2-3.

Conclusions: Despite higher rate of DGF, recipients ≥ 65 tolerate AKIN 2-3 kidneys well and have equivalent outcomes to those receiving AKIN 0-1 kidneys. As expected, death with functioning graft is the primary cause for graft loss in older recipients. Older recipients should not be excluded from receiving kidneys from severe AKI donors.



Outcomes for recipients ≥ 65

	AKIN 0-1	AKIN 2-3	P

Abstract# 855

Efficacy of Hope: Analysis of Quality HIV+ Deceased Donor Organ Availability

G. E. Owens[1], B. Shelton[1], P. MacLennan[1], D. Sawinski[2], J. E. Locke[1], *[1]Transplant, University of Alabama at Birmingham, Birmingham, AL, [2]Transplant, University of Pennsylvania, Philadeplphia, PA*

Purpose: The purpose of this study is to understand the number of organs actually available for HIV+ to HIV+ transplant utilizing data on a national scale, while taking into account organ quality.

Methods: Using data collected at Center for AIDS Research Network of Integrated Systems (CNICS) centers (1995 - 2018), 6,223 deaths (potential deceased organ donors) among PLWH were identified. 1,137 were excluded due to cancer diagnosis. The remaining 5,086 were studied to assess organ quality/suitability. Potential deceased organ donors were further characterized as high (viral load > 200 copies/mL and CD4 < 200 cells/mm^3) or low (viral load < 200 copies/mL and CD4 > 200 cells/mm^3) risk for transmission of resistant virus. Kidney quality was assessed using the Kidney Donor Profile Index (KDPI) with a KDPI > 85 indicating poor quality. Liver viability was assessed via Fibrosis-4 (FIB-4) score, which measures AST, ALT, platelet count, and age, with a FIB-4 score > 3.25 indicating severe cirrhosis rendering the donor liver not suitable for transplantation.

Results: In 1995, 100% of PLWH were considered high risk compared to just 42% in 2017 [figure]. 3,907 potential donors were high risk. Among low risk potential donors, 605 (9.72%) had a KDPI < 85, suggestive of high quality kidneys for transplant, and 967 (15.54%) had minimal (FIB-4 < 1.45) to moderate cirrhosis (FIB-4 1.45-3.25), suggestive of high quality livers for transplant. Importantly, 316 (32.7%) of potential liver donors were coinfected with hepatitis C.

Conclusions: Since the introduction of antiretrovirals in the 1990's, HIV care is increasingly more accessible, targeted, and effective, and thus, over time fewer potential donors were high risk. During the 23 years covered by this study, only 25% of deaths occurred among low risk PLWH with laboratory and clinical features suggestive of high quality, transplantable organs.

Abstract# 857

Excellent Outcomes of Kidney Transplantation from Hepatitis C Infected Donors

B. Rawashdeh, J. Dann, K. M. Marsh, A. Doddi, S. Rao, A. Agarwal, *UVA Health System, University of Virginia, Charlottesville, VA*

Purpose: Utilization of Hepatitis C viremic (HCV D+) kidney donors in HCV naïve recipients has increased in the United States. While there are shorter waiting times to receive HCV D+ organs, there is a need for HCV therapy and possible higher rates of other viral infections including cytomegalovirus (CMV) and polyomavirus virus (BK). We conducted this study to compare the outcomes of HCV D+ and HCV D- with a focus on viral infections.

Methods: A retrospective chart review was conducted to identify deceased donor kidney transplant recipients from December 1, 2018 to November 30, 2019 at a large single-center transplant center. Primary outcome was 1-year patient and kidney allograft survival. Details of kidney allograft function, rejection, HCV therapy, and viral infections were recorded. The recipients were divided into 2 groups according to donor HCV status: HCV D+ (n= 31) and HCV D- (n= 95).

Results: The groups had similar age (59 vs 56 years, p=0.3), gender (68 vs 55% male, p=0.2), race (Caucasian 55 vs 53%, African American 42 vs 38%, p=0.7), chronic dialysis (94 vs 89%, p=0.5) and dialysis vintage (4 years for both groups, p=0.5). The HCV D+ group had higher BMI (33 vs 30 kg/m2, p =0.03), more primary transplants (97% vs 80%, p =0.02) and lower mean PRA (6 vs 26, p =0.049). Comorbidities were frequent but similar between groups: HTN (90%), DM (44%), CAD (28%) and PAD (5%). Donors in the HCV D+ group were younger (36 vs 45 years, p=0.04) but the proportion of donors with terminal creatinine > 1.5mg/dl was higher (61% vs 34%, p =0.007). While the allocated KDPI was similar, the optimized KDPI was lower in the HCV D+ group (35% vs 55%, p <0.001). Delayed graft function (DGF) (54%) and cold ischemia time (CIT) (22 hours) were similar for the 2 groups. Twenty-nine HCV D+ recipients acquired HCV viremia due to donor transmission; 2 recipients in the HCV D- cohort had HCV viremia prior to transplant. All of these recipients were treated post-transplant and achieved sustained virologic response at 12 weeks. Transaminitis occurred in 9 recipients, with at least 3 times normal aminotransferase levels; no recipients had evidence of advanced hepatic dysfunction. The 1 year patient survival was excellent in HCV D+ recipients (100%) and was similar to HCV D- recipients (90%, p=0.1). No additional kidney allografts were lost at 1 year post-transplant, and both groups had similar GFR at 1 year (56 vs 60 ml/min/1.73 m^2, p=0.4). CMV and BK infections occurred at similar rates (35 vs 21%, p=0.08 and 26 vs 21%, p=0.6, respectively).

Conclusions: Our study shows that HCV D+ kidneys can be safely utilized with excellent patient and kidney allograft outcomes. The rates of viral infection were not associated with donor HCV status. HCV D+ kidneys with AKI and long CIT have high rates of DGF, but the short term outcomes are favorable. These results support a more liberal criteria for HCV D+ kidneys for transplantation.

Abstract# 858

Donation After Circulatory Death Kidney Transplantation Has Equal Long-Term Graft and Patient Survival as Donation After Brain Death: A Systematic Review and Meta-Analysis

E. Rijkse[1], S. Ceuppens[1], H. Qi[2], J. N. IJzermans[1], D. A. Hesselink[3], R. C. Minnee[1], *[1]HPB/Transplant surgery, Erasmus Medical Center, Rotterdam, Netherlands, [2]Biostatistics, Erasmus Medical Center, Rotterdam, Netherlands, [3]Nephrology and Transplantation, Erasmus Medical Center, Rotterdam, Netherlands*

Purpose: Donation after circulatory death (DCD) kidneys are not worldwide accepted yet due to concerns about inferior quality. To investigate whether these concerns are justified, a meta-analysis was performed to assess DCD graft survival compared to donation after brain death (DBD) graft survival. Secondary outcomes were the risk of primary non-function (PNF), delayed graft function (DGF), acute rejection (AR) within 3 months, 1-year estimated Glomerular Filtration Rate (eGFR), patient survival, and risk of urologic complications.

Methods: EMBASE, Medline, Cochrane, Web of Science and Google Scholar databases were searched for studies published until September 15th, 2020. Studies comparing DCD to DBD for any of the outcomes were included. Exclusion criteria were: studies using normothermic machine perfusion or regional perfusion and studies reporting on pediatric/dual kidney transplants. A random-effects model was used for meta-analysis. Meta-regression analysis was performed if I^2 exceeded 50%.

Results: 1808 studies were screened, 51 studies were included. The risk of 1-year all-cause and death-censored graft loss was increased in DCD recipients (risk ratio (RR) 1.13 (1.08-1.19) and RR 1.10 (1.04-1.16)). The risk of 10-year all-cause and death-censored graft loss (RR 1.03 (0.94-1.13) and RR 1.02 (0.92-1.13)) was equal to DBD recipients. DCD recipients had a higher risk of PNF (RR 1.43 (1.26-1.62)) and DGF (RR 2.02 (1.88-2.16)). The risk of AR and 1-year eGFR was similar to DBD. One-year mortality risk was increased in DCD recipients (RR 1.10 (1.01-1.21), while the 5-year and 10-year mortality risk were similar to DBD. The risk of ureter leakage/stenosis was not significantly different.

Conclusions: DCD kidney transplant recipients have similar long-term graft and patient survival as DBD recipients despite a higher risk of PNF and a higher risk of mortality and graft loss in the first year. These results should encourage implementation of DCD programs worldwide to increase the donor pool.

Abstract# 859

Prolonged Cold Ischemic Time Demonstrating Minor Effect on Outcomes Following Renal Transplantation - A Paired Kidney Analysis

N. Sanichar[1], V. Sandra[2], K. L. King[2], S. A. Husain[2], S. Mohan[2], *[1]Columbia University Irving Medical Center, New York, NY, [2]Columbia University, New York, NY*

Purpose: An improved understanding of the effects of cold ischemia time (CIT) on deceased donor kidney (DDK) outcomes may increase organ utilization by clarifying the detrimental impact on outcomes. We performed a paired analysis of DDKs with long CIT to measure its impact on delayed graft function (DGF) and death-censored graft survival (GS).

Methods: Using national UNOS data, we identified 6,234 pairs (by donor) of transplanted DDKs from January 2000 to February 2020 with CIT above the US median (16 hours) and at least 5 hours apart. Among 1,955 pairs with discordant DGF status, we analyzed the impact of recipient factors and shorter versus longer CIT on DGF and 10-year GS using logistic regression and the log-rank test.

Results: Recipients were predominantly male with a mean age of 55.4 ± 12.4 years. The kidney pairs had a median CIT difference of 10 hours between the shorter and longer CIT kidneys. The DDK with shorter CIT in the pair experienced DGF 45.3% of the time, vs 54.7% for the DDK with longer CIT. The longer CIT kidneys had an increased odds ratio for DGF compared to the shorter CIT kidneys in the pair (OR=1.44, 95% CI: 1.25-1.67, p<0.0001), but no different 10-year GS (logrank p=0.36). Kidneys that experienced DGF, however, experienced worse 10-year GS than the non-DGF group (logrank p <0.001). Among the 1,955 kidneys with shorter CIT, recipients who were male, black, had a higher body mass index (BMI), or had a longer dialysis vintage had an increased odds of DGF (Table 1).

Conclusions: In a paired analysis of long CIT kidneys, DGF is associated with worse 10-year GS. When discordant in donor kidney pairs, DGF is likely the result of recipient factors, especially when it occurs in the kidney that experienced less CIT.

Abstract# 860

A Kidney Waitlist Outcomes Timeline to Visualize Candidate Offers and Outcomes

C. Schaffhausen[1], J. Miller[2], A. Matas[3], A. Israni[4], A. Wey[5], A. Hart[4], *[1]Hennepin Healthcare Research Institute / University of Minnesota (UMN), Minneapolis, MN, [2]Chronic Disease Research Group, Minneapolis, MN, [3]Department of Surgery, UMN, Minneapolis, MN, [4]Hennepin Healthcare / UMN, Minneapolis, MN, [5]Scientific Registry of Transplant Recipients, Minneapolis, MN*

Purpose: While transplant centers closely monitor posttransplant outcomes for each transplant recipient, centers currently lack data to monitor waitlist outcomes of individual candidates. Candidates who are waiting may receive multiple deceased donor organ offers. Centers may decline offers on behalf of the candidate in order to wait for a better offer. These decisions may impact waitlist outcomes because a better offer may not arrive, and dialysis-related morbidity may worsen. We sought to develop waitlist outcomes reports to facilitate monitoring of candidates who are receiving donor offers.

Methods: Multiple report mockups were developed using patient-level data from the Scientific Registry of Transplant Recipients (SRTR). Data included a deidentified random sample of 200 kidney waitlist candidates from across the US who had received at least one offer between May 7, 2019 and May 6, 2020. For each candidate, offers were identified from match runs from January 1, 2014 to May 6, 2020. Match run data included any offer that was ultimately accepted somewhere and resulted in a transplant. Mockups excluded candidates with multiple listings.

Results: Reports were designed to visually identify several outcomes: candidates who had died after receiving offers, additional time on dialysis for candidates receiving offers, and changes to quality and frequency of donor offers over time. Figure 1A depicts multiple patients on a waitlist. Each horizontal line represents one candidate and each mark represents an offer to the candidate. Figure 1B depicts an alternative report showing a single candidate who was an example of offer Kidney Donor Profile Index (KDPI) not improving over time.

Conclusions: The waitlist reports are a potential method for centers to self-monitor candidates and may supplement posttransplant outcomes monitoring and existing decision support tools, such as statistical outcomes calculators. The reports illustrate how offer frequency and KDPI change while candidates wait and the dialysis burden faced by candidates. Future stakeholder feedback will inform improvements and alternatives to reports and identify additional relevant candidate and donor data (e.g. offer number). Additional research is warranted to understand the utility of a visual representation of the impact of offer decisions made on behalf of waitlist candidates.

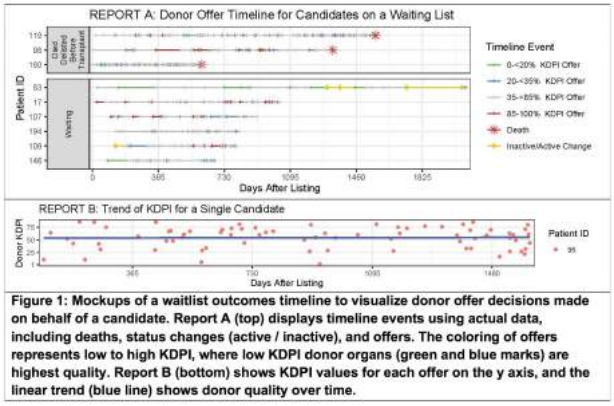

Figure 1: Mockups of a waitlist outcomes timeline to visualize donor offer decisions made on behalf of a candidate. Report A (top) displays timeline events using actual data, including deaths, status changes (active / inactive), and offers. The coloring of offers represents low to high KDPI, where low KDPI donor organs (green and blue marks) are highest quality. Report B (bottom) shows KDPI values for each offer on the y axis, and the linear trend (blue line) shows donor quality over time.

Abstract# 861

Outcomes After Usage of Organs from Deceased Organ Donors with Sepsis - A Single-center Experience

A. Sharma[1], D. Choudhary[1], D. Kenwar[1], S. Singh[1], S. kumar[1], K. jain[2], N. Bansal[3], A. Ravi[1], *[1]Renal & Pancreas Transplant Surgery, Postgraduate Institute of Medical Education and Research, Chandigarh, Chandigarh, India, [2]Anesthesiology, Postgraduate Institute of Medical Education and Research, Chandigarh, Chandigarh, India, [3]Transplant Coordinator, Postgraduate Institute of Medical Education and Research, Chandigarh, Chandigarh, India*

Purpose: The deceased Organ Donation rate is around 0.8/million in our nation. There remains a severe shortage of organs worldwide, leading to a trend towards relaxing acceptance criteria for using organs. However, after these donations, outcomes need to be carefully analyzed to have guidelines for the safe use of organs from these donors. The present study analyzed the outcomes after using organs from Deceased Organ Donors (DOD) with sepsis in a kidney-pancreas transplant program at a tertiary care hospital

Methods: Data from January 2016 -October 2019 was analyzed from the local database. A total of 118 DOD were identified. 37/118(31.3%) fulfilled the criteria of ongoing sepsis any time before organ donation. Sepsis was defined as a positive blood/urine/tracheal aspirate cultures and a positive Sequential Organ Failure Assessment score (SOFA). Cultures sent on any day after ICU admission till organ procurement were included. Parametric and nonparametric multivariate analysis was done among these DODs

Results: Over 95% of donors had brain death due to road traffic accidents with a mean ICU stay of 7.3+ 6.3 days. 235 recipients received kidneys and pancreas from these donors, and 73 of these were from septic donors. Among 37 septic organ donors, 19 had multiple drug-resistant organisms (MDRO) on cultures, most commonly being Acinetobacter baumannii. A total of 6/235 Recipients had died during the hospital stay, with most (5/6) of these in patients who received kidneys from septic donors. Recipients from septic donors had Significantly higher DGF rates, required more post-op re-explorations (11. Vs. 4.9%), and had longer ICU stay, 19.8 vs. 15.6 days

Conclusions: Organ transplantation from donors with sepsis resulted in higher mortality in the early post-op period. There is a need to characterize risk factors associated with mortality in these donors. However, long-term outcomes were similar in patients who recovered

Total (n-236)	Sepsis YES (n-recipient)	Sepsis NO (n-recipient)	Multivariate significance
DCD/DBD	7/66 (73)= 31.0%	4/159 (162) = 68.9%	
Recipient age & Donor Age	41.6 & 35	40.8 & 35.5	
Cold ischemia Time(min)	347.41	357.87	
DGF	38.4%	19%	.002
In stay Rejection	8.2%	11.6%	
Discharge sCr vs follow-up sCr (mg/dl)	1.67 vs 1.29	1.50 vs 1.09	
Patient survival at 3 years	62/73= 84.9%	148/162= 91.3%

Abstract# 862

Poor Reliability of Karnofsky Performance Score in Kidney Transplant Candidates

M. R. Stedman, D. J. Watford, G. M. Chertow, J. C. Tan, *Medicine, Stanford University, Palo Alto, CA*

Purpose: The Karnofsky Performance Status (KPS) Scale has been used as a proxy for frailty and as a predictor of transplant outcomes, however reliability of the instrument in national transplant data registries is unknown. We investigate the inter-rater reliability of KPS reporting among transplant centers to assess its utility as a measure of physical function in kidney transplant candidates.

Methods: Patients were selected from the Scientific Registry of Transplant Recipients (SRTR) database between 2006-2020 with at least two KPS scores in a three-month period. The reliability of KPS was estimated from the intraclass correlation coefficient (ICC) in a multilevel model with patient and center level random effects. All analyses were adjusted for the time elapse between measurements, year reported, patient demographics and comorbid conditions.

Results: Among the 8,197 patients observed, 5,348 (65%) had a KPS score in the normal range (80-100 points) and only 87 (1%) had scores in the disabled range (0-40). We found substantial variability and poor reliability in KPS reporting between centers. Roughly one third of candidates had scores that varied 20-80 points in difference (See Table: Range between the maximum and minimum scores.) The Interrater reliability between centers was estimated to be 23% (95% CI: 21%, 25%) agreement, where estimates below 50% are considered poor.

Conclusions: Conclusions: Poor reliability in KPS reporting raises concerns for its utility as a measure of physical function and proxy for frailty. Kidney transplant candidates are a unique population that require a less subjective and more precise instrument for risk assessment.

Abstract# 863

Use of Hepatitis B N.A.T. Positive Kidneys in Hepatitis B Immune Recipients

E. Stephenson[1], B. Nangunuri[2], T. McCune[3], *[1]Nephrology and Critical Care, Eastern Virginia Medical School, Norfolk, VA, [2]Eastern Virginia Medical School, Norfolk, VA, [3]Nephrology, Eastern Virginia Medical School, Norfolk, VA*

Purpose: There is an increasing demand for kidney donations as roughly 4000 people die on the waitlist each year while the number of kidneys being discarded has continued to increase[1,2]. Despite use of Hep C positive kidneys, thousands of kidneys are discarded annually[3]. Nucleic Acid Test (NAT) is a rapid test used to detect presence of a virus prior to serologic conversion and the false positive rate remains unknown[4]. We present nine patients with hepatitis B surface antibodies of >100 mIU/mL that received renal transplants from NAT positive donors without evidence of seroconversion.

Methods: During annual transplant evaluation, HBsAb quantitative levels were obtained. Patients with HBsAb >100mIU/mL were offered to accept Hep B antigen negative, Hep B NAT positive kidneys with informed consent. From July 2019 - July 2020, 9 patients were transplanted with Hep B NAT positive kidneys. Hep B NAT and Hep B surface antigen were checked at 4 weeks, 12 weeks and 12 months postoperatively. Hep B surface antibody and Hep B core antibodies were performed 6 months post-transplant.

Results: None of our patients experienced seroconversion or active viremia to date. Three patients will complete one year surveillance on June 2021 (Table 1). Due to small sample size, no statistical analyses were performed. Evaluation of our cohorts wait time compared to matching blood types is ongoing.

Table 1. Recipients of Hep B NAT+ kidney transplant and graft function at 1 year. NR =Non-reactive

Patient ID	Gender	Age (years)	KDPI %	HBsAb quantitative value (mIU/mL)	12 week/ 1 year Hep B NAT	Creatinine 1 year post transplant (mg/dL)
1	Male	54	70	>150	NR/NR	1.1
2	Male	41	70	>150	NR/NR	1.1
3	Female	67	59	>150	NR/NR	1.1
4	Male	68	59	>150	NR/NR	1.3
5	Male	64	40	122.8	NR/NR	1.4
6	Male	71	40	>150	NR/NR	1.2

Conclusions: We have successfully transplanted nine NAT positive kidneys into patients with immunity to Hep B without inducing active hepatitis. Our results support the use of Hep B NAT positive donors into recipients with high levels of immunity. This may assist in decreasing the number of discarded kidneys but further research is needed.

Abstract# 864

Can Procurement Biopsy Data Tell Us Anything? The Influence of Interstitial Fibrosis on Long-term Kidney Graft Survival

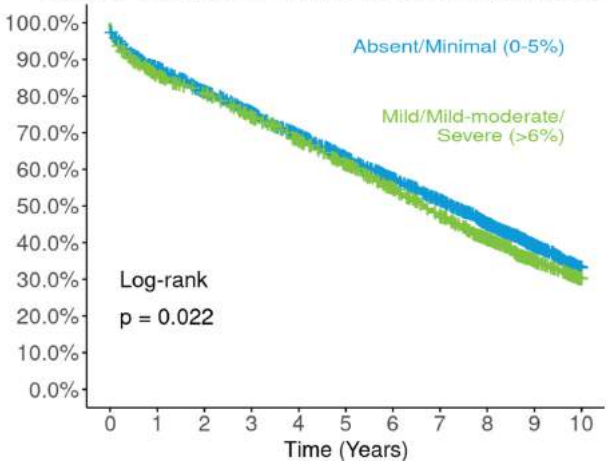
D. Stewart[1], J. Foutz[1], L. Kamal[2], H. McGehee[1], P. Saravanane[2], S. Yu[3], R. Yousfi[2], G. Gupta[2], *[1]Research, United Network for Organ Sharing, Richmond, VA, [2]Virginia Commonwealth University Health, Richmond, VA, [3]Research, Virginia Commonwealth University Health, Richmond, VA*

Purpose: Biopsy findings have been shown to have a profound impact on kidney utilization decisions. Most studies of the association between procurement biopsy findings and kidney recipient outcomes have been limited in scale and focused on short-term survival. With a goal of aiding transplant decision-making, the BARETO (Biopsy, Anatomy, and Resistance Effects on Transplant Outcomes) national registry study unlocks previously trapped biopsy and anatomy data on DonorNet attachments to assess relationships between these findings and long-term renal graft outcomes.

Methods: Data were manually entered for a preliminary cohort of 4,125 ECD donor solitary kidney transplants from 2008-2011. Interstitial fibrosis (I/F) was characterized as absent/minimal (0-5%) or mild+ (≥6%). Analyses include Kaplan-Meier all-cause graft survival and 3 types of Cox models (propensity weighted, multivariable regression, and doubly robust regression (DRR)) to adjust for 18 possible confounders.

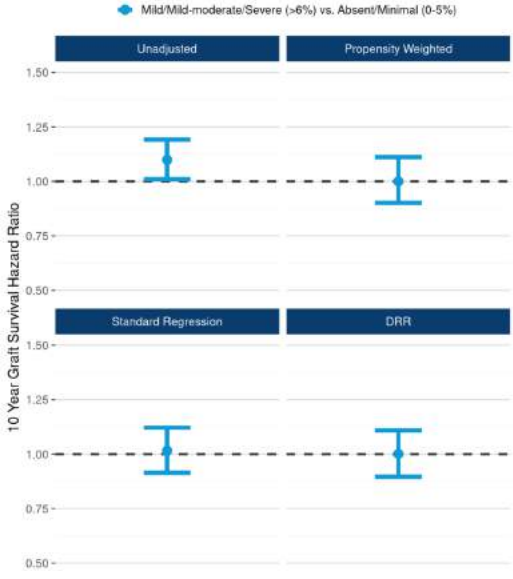
Results: Survival curves suggest a reduction in long term graft survival for kidneys having mild or worse I/F (p=0.022, Fig 1).

Fig 1. Ten-Year All-Cause Graft Survival by Interstitial Fibrosis



However, after risk adjustment (Fig 2) this effect was negated (HR 1.00, 95% CI: 0.90, 1.11 in DRR), suggesting these observed differences may be entirely attributable to correlations with other factors, namely glomerulosclerosis and ischemia time.

Fig 2. All-Cause Graft Failure Hazard Ratios by Interstitial Fibrosis



Conclusions: Robust causal inference methods suggest that the independent association between I/F and long term graft survival is very small or non-existent, challenging this parameter's relevance in kidney utilization decisions.

Abstract# 865

The Impact of High Kdpi on 1-year Post-transplant Graft Function and Survival in a Brazilian Cohort

H. Tedesco Silva Junior, R. Demarchi Foresto, M. Hazin, B. Cassão, A. Aquino, J. Taddeo, C. Rosso Felipe, L. Requião Moura, J. Medina, *Núcleo de Ensino e Pesquisa, Hospital do Rim, Universidade Federal de São Paulo, São Paulo, Brazil*

Purpose: To evaluate the impact of High Kidney Donor Profile Index (KDPI) on 1-year post-transplant renal function and graft survival.

Methods: This retrospective cohort analyzed 3,059 deceased donor kidney transplants performed between January 2013 and December 2017 in a high-volume center in Brazil. They were divided into 4 groups according to KDPI values: Group A-KDPI 0-35 (n=561), Group B-KDPI 36-50 (n=361), Group C-KDPI 51-85 (n=1,289), and Group D-KDPI >85 (n=848) and were followed during the first year post-transplantation. GFR was estimated according to the CKD-EPI formula. Sensitive analysis of GFR used last observation carried forward imputation method for death and set at 0 ml/min/1.73m^2 for graft loss.

Results: Recipients of kidneys with KDPI>85% were older and more frequently had hemodialysis as previous treatment. A higher proportion received kidneys from older, non-black, and female donors with hypertension and diabetes. Median cold ischemia time was similar and high in all groups (23h; p=0.513). The incidence of DGF were A=50.6%, B=59.3%, C=62.7% and D=62.0% (p<0.001). Median GFR were A=64.8 (50.1-82.4), B=53.3 (38.8-68.6), C=46.9 (34,5-59.6) and D=39.1 (26.8-50.5) ml/min/1.73m^2 (p<0.001), respectively (Figure 1). Biopsy-proven acute rejection (A=9.1%, B=9.8%, C=8.4%, D=9.1%, p=0.736) and graft survival (A=93.6%, B=91.1%, C=92.7%, D=90.0%, p=0.051) were similar between groups. In the ROC curve, increased values of KDPI were correlated to GFR <50ml/min/1.73m^2 with an AUC of 0.702 (IC 95% 0.684-0.721; p<0.001). In multivariate analysis, increased values of KDPI were related to GFR <50ml/min/1.73m^2 (OR 1.23; CI 95% 1.02-1.026; p<0.001).

Conclusions: In a single-center cohort of deceased donor kidney transplants with high cold ischemia time and high incidence of DGF, KDPI is correlated to GFR at 1-year post-transplantation. The median values of GFR were lower among those with high KDPI. Besides that, 1-year graft survival was similar between groups

Figure 1. Boxplot comparing median GFR between KDPI groups.

Abstract# 866

The Edge of Glory: Determinants of Success and Failure for Prolonged Cold Ischemia in Kidney Transplantation

A. Turner[1], M. Hamidi[1], V. Ariyamuthu[2], R. Harland[1], B. Tanriover[2], *[1]Surgery, Banner University of Arizona Medical Center, Tucson, AZ, [2]Medicine, Banner University of Arizona Medical Center, Tucson, AZ*

Purpose: Prolonged cold ischemia time (CIT>30 hours) is associated with an increased risk of primary non-function and early graft loss in kidney transplantation, although this risk is incompletely characterized. We sought to evaluate outcomes of kidney transplants at our center with CIT>30 hours from 2010-2019.

Methods: 166 kidney transplants with CIT>30 hours were performed at our center from 2010-2019. We compared transplants with graft loss (n=20) and EGFR<40 ml/min (n=39) at 1 year (total n=59) to transplants with eGFR>40 ml/min at 1 year (n=107) with multivariable logistic regression using backward stepwise variable selection (p<0.1). Variables included recipient age, gender, race, BMI, DM, re-transplantation, EPTS, cPRA; donor age, terminal creatinine, CIT, anastomosis time, pump status, terminal pump flow and resistive index, KDPI, recovery/post perfusion biopsy Remuzzi score, and DCD status.

Results: There were no significant demographic differences between recipients of either group. The average cold ischemia time was similar between groups, 40±6 hours (p=0.59). Transplants with graft loss or eGFR<40 ml/min at one year were more likely to be DCD donors (47.5% vs. 25.2%, p=0.004; OR=3.95, 95% CI=1.64-9.50), or higher KDPI (66±19% vs. 59.6±21%, p=0.04; OR=1.31, 95% CI=1.03-1.69). Kidneys with graft loss or eGFR<40 ml/min at one year were less likely to have been placed on machine pulsatile perfusion (76% vs. 90%, p=0.05; OR=0.19, 95% CI=0.06-0.61).

Conclusions: Successful utilization of kidneys with prolonged cold ischemia time is possible with careful donor selection. Graft loss and eGFR<40 ml/min at one year is associated with kidneys transplanted from DCD donors and those with high KDPI. Machine perfusion may mitigate the risk of prolonged CIT.

Recipients of deceased donor kidneys with CIT more than 30 hours (2010-2019)			
N=166	eGFR>40 ml/min at 1 year	eGFR<40 ml/min at 1 year and/or failed allograft	P-value
N	107	59	
Recipient age	61.8 ±11.0	63.4 ±10.5	0.36
DM %	56.1	59.3	0.69
BMI	28.5 ±5.0	28.8 ±5.1	0.71
EPTS, %	57.7 ±31.8	56.2 ±32.8	0.78

Deceased donor kidneys with CIT more than 30 hours (2010-2019)			
N=166	eGFR>40 ml/min at 1 year	eGFR<40 ml/min at 1 year and/or failed allograft	P-value
KDPI, %	59.6 ±21.0	66.4 ±19.1	0.04
DCD, %	25.2	47.5	0.004
Pump, % (n=123)	90.0	76.7	0.05

Abstract# 867

Long Term Outcomes of Kidney Transplantation from Deceased Donors with Terminal Acute Kidney Injury

J. Rogers[1], R. Stratta[2], A. Farney[2], G. Orlando[2], C. Jay[2], A. Reeves-Daniel[3], A. Mena-Gutierrez[3], N. Sakhovskaya[3], K. Gurung[2], B. Sharda[2], J. Rogers[2], *[1]Surgery, Wake Forest School of Medicine, Winston Salem, NC, [2]Surgery, Wake Forest Baptist Medical Center, Winston Salem, NC, [3]Internal Medicine, Wake Forest Baptist Medical Center, Winston Salem, NC*

Purpose: Long term outcomes of kidney transplantation from deceased donors with terminal acute kidney injury (AKI) are not well defined.

Methods: Single center retrospective review of all deceased donor kidney transplants from 1/31/07-9/1/19. AKI donor kidneys were defined by a doubling of the donor's admission serum creatinine (SCr) level and a terminal SCr > 2.0 mg/dl before organ recovery.

Results: 185 AKI donor kidneys were transplanted during the study period, including 147 kidneys from standard criteria donors (SCD), 26 from expanded criteria donors (ECD), and 12 from donation after cardiac death (DCD). Mean donor age was 36 years (range 1 - 69 years); mean admission and terminal SCr levels were 1.3 mg/dl and 3.1 mg/dl, respectively (mean terminal eGFR 32 ml/min). With a mean follow-up of 78 months, actuarial graft survival was comparable to concurrent kidney transplants from brain-dead non-AKI SCD's at our center (Table 1). Patient survival was similar between groups. Delayed graft function (DGF) occurred in 87 patients (47%) vs. 22% in recipients of non-AKI SCD kidneys ($p < 0.001$). Mean SCr at 48 months was 1.61. DGF was associated with lower graft survival in recipients of both AKI (Table 2) and non-AKI (Table 3) SCD kidneys but the impact was earlier and more pronounced in non-AKI recipients.

Conclusions: Despite having a significantly higher incidence of DGF, kidneys from deceased donors with terminal AKI have long term outcomes that are comparable to non-AKI SCD kidneys and represent a safe and effective method to expand the donor pool.

Table 1. Kidney Graft Survival				
	1-year	**3-year**	**5-year**	
AKI	95%	88%	74%	
Non-AKI	95%	85%	76%	P=NS

Table 2. AKI Kidney Graft Survival: DGF vs No DGF				
	1-year	**3-year**	**5-year**	
No DGF	97%	89%	84%	
DGF	92%	89%	67%	P=0.025

Table 3. Non-AKI Kidney Graft Survival: DGF vs. No DGF				
	1-year	**3-year**	**5-year**	
No DGF	97%	90%	81%	
DGF	86%	69%	60%	P<0.001

Abstract# 868

Identifying Barriers to Transition Readiness in Pediatric Kidney Transplant Patients

K. Amatya, S. Yuhas-Schiltz, C. Petyak, A. Moudgil, *Nephrology, Children's National Medical Center, Washington, DC*

Purpose: Inadequate readiness for transition from pediatric to adult care is associated with loss of transplant, initiation of or return to dialysis, and other negative outcomes after transition. Graft failure rate is reported to range from 30% to 35% among renal transplant youth after transition to adult providers. Differences in the patient and family's goals and expectations and shifts in responsibilities around healthcare behaviors, perception of healthcare provider roles, and health literacy around adult health care systems may all present as risk factors in transition readiness. The purpose of this study is to identify and address barriers to transition preparedness, a crucial part of health care management in pediatric patients from pre- or early teen years in order to set them on a path to successful post-transition care.

Methods: Participants were 21 post-kidney transplant patients followed at a major pediatric hospital. Mean age at participation was 18.2 years and mean age at transplant was 11.6 years. Patients were administered the STARx Questionnaire, a validated measure of medical transition readiness and the Readiness for Transition to Adult Care Assessment Tool, a survey of transplant-related transition readiness as a part of a multidisciplinary transition program.

Results: On the STARx Questionnaire, patients reported lowest average scores (1-5 scale) on asking providers about medical care (mean= 3.2) and using internet, books, or other guides to learn more about illness (mean= 2.75). On the Readiness for Transition survey lowest averages (0-2 scale) were observed on knowledge of target medication levels (mean=1.45), make and keep track of appointments (mean= 1.4), and knowledge about health insurance (mean= 1.1). The average score for preparedness for transition was 7.2 (0-10 scale) and for confidence in transition success was 6.9 (0-10 scale).

Conclusions: Adolescents and young adults in pediatric transplant programs present with a variety of barriers to transition success. It is important to identify patients who are struggling with developmentally appropriate engagement in health care behaviors. Education about illness from providers and external forums, making appointments, and learning about health insurance policies may prepare youths for transition and practicing healthcare skills while under pediatric care may also increase confidence in success after transition. Further research on assessment of readiness and interventions to improve readiness is needed.

Abstract# 869

Greater Social Vulnerability is Associated with Self-advocacy in the Living Donor Navigator Program

A. Carter, A. C. Kale, R. D. Reed, B. A. Shelton, H. Qu, M. C. McLeod, B. J. Orandi, R. M. Cannon, D. Anderson, P. MacLennan, V. Kumar, M. Hanaway, J. E. Locke, *University of Alabama at Birmingham Hospital, Birmingham, AL*

Purpose: The Living Donor Navigator (LDN) program helps transplant candidates identify live donors by pairing them with an advocate - a friend or family member trained to speak on their behalf. Some candidates are unable to identify an independent advocate and undergo LDN advocacy training alone as self-advocates. The self-advocate phenotype mirrors that of other vulnerable populations and is associated with decreased likelihood of LDKT. The purpose of this study was to examine the association between social vulnerability and LDN self-advocacy.

Methods: This single center, retrospective cohort study included 110 transplant candidates with Alabama residences who enrolled in the LDN program between 04/2017-06/2019. Social vulnerability measures at the census tract-level were obtained from the CDC's Social Vulnerability Index (SVI), which is comprised of 15 social factors based on data collected from the US census. Modified Poisson regression was used to evaluate the relative risk of self-advocacy associated with social vulnerability.

Results: Of the 110 candidates, 19% (n=21) were self-advocates. LDN participants had 17% higher risk of self-advocacy for every 10-percentage point increase in overall SVI (adjusted relative risk (aRR) 1.17, 95% Confidence Interval (CI): 1.03-1.32, p=0.01; Table 1, Figure 1). Living in areas with more unemployment (aRR: 1.18, 95%CI: 1.04-1.33, p=0.02), single parent households (aRR: 1.23, 95%CI: 1.06-1.42, p=0.006), minority status (aRR: 1.30, 95%CI: 1.04-1.55, p=0.02), or no vehicle households (aRR: 1.17, 95%CI: 1.02-1.35, p=0.02) was significantly associated with increased risk of self-advocacy (Table 1).

Conclusions: LDN participants living in more socially vulnerable areas had increased risk of self-advocacy. Community-level vulnerability may limit transplant candidates' ability to engage with the LDN program as designed. LDKT programs should address individual- and community-level vulnerability to create culturally competent solutions for mitigating disparities in LDKT.

Table 1. Modified Poisson models for relative risk of self-advocacy for every 10-percentage point increase in SVI measures

SVI	Adjusted	
	Relative Risk (95% CI)	p - value
Overall	1.17 (1.03, 1.32)	0.01
Unemployment	1.18 (1.04, 1.33)	0.02
Single Parent Household	1.23 (1.06, 1.42)	0.006
Minority Status	1.30 (1.04, 1.55)	0.02
No Vehicle	1.17 (1.02, 1.35)	0.02

Every row represents a different model adjusted for transplant candidate gender, age, race, and whether the candidate lives alone

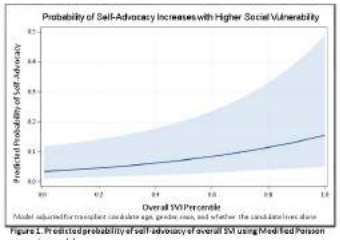

Figure 1. Predicted probability of self-advocacy of overall SVI using Modified Poisson regression model

Abstract# 870

Health-related Quality of Life (HRQoL) in Patients on Dialysis and Kidney Transplant Recipients - Experience with the PROMIS Global-10 Survey

G. Chawla, W. Hajjar, M. Dastgheib, N. Yanga, G. Ahmadzadeh, N. El-Dassouki, A. Shahreza, N. Al Kaabi, N. Edwards, I. Mucsi, *University Health Network, Division of Nephrology and Multi-Organ Transplant Program, Toronto, ON, Canada*

Purpose: The PROMIS (Patient-Reported Outcomes Measurement Information System) Global-10 survey has been used to assess HRQoL in population surveys and studies including patients with chronic medical conditions but not in patients with chronic kidney disease (CKD). Here we compare HRQoL between kidney transplant recipients (KTR) and patients on dialysis using the PROMIS Global-10 survey.

Methods: A cross-sectional convenience sample of adult KTRs and patients on dialysis completed the 10 item PROMIS Global-10 which yields a Global Physical Health (GPH) and a Global Mental Health (GMH) score. Sociodemographic and clinical characteristics were also collected. The two-sample t-test and multivariable linear regression were used to compare HRQoL between groups. Multiple imputation by chained equations was used to handle missingness.

Results: 355 patients (mean(SD) age 55(15) years, 61% male, 52% White, and 61% transplanted) were enrolled. Patients on dialysis vs KTRs were older (mean[SD] age 62[14] vs 51[14] years), less likely to be White 34% vs. 63%), and to have more than 12 years of education (43% vs. 73%.); p<0.001 for all. Compared to patients on dialysis, KTRs had significantly higher GPH (47[9] vs. 43[11], p<0.001) and GMH (49[10] vs 47[11], p= 0.048). The proportion of patients with "impaired HRQoL" (GPH or GMH <45, 5-point, i.e. half SD below general population mean, i.e. 50), was lower among KTRs (48% vs 71%, p<0.001, and 35% vs 48%, p=0.016 for GPH and GMH, respectively). After adjusting for age, sex, marital status, ethnicity, income, education, and comorbidity in linear regression, GPH (b=2.52, 95%CI: 0.1 - 4.9, p= 0.038) but not GMH (b=0.90, 95%CI: -1.8- 3.6, p= 0.504) was significantly higher in KTRs.

Conclusions: The PROMIS Global-10 GPH but not GMH was higher among KTRs compared to patients on dialysis. Further studies are needed to assess the value of this brief, widely validated tool in assessing HRQoL among patients with CKD.

Abstract# 871

The Impact of Health Literacy on Kidney Transplant Listing

G. Chen[1], J. Siahaan[2], L. Leon Novelo[2], I. Rizvi[3], A. M. De Golovine[4], A. R. Edwards[4], A. Pai[4], W. A. Dar[3], *[1]Abdominal Transplant, Memorial Hermann Hospital, Houston, TX, [2]Department of Biostatistics and Data Science, School of Public Health The University of Texas Health Science Center at Houston, Houston, TX, [3]Department of Surgery, McGovern Medical School The University of Texas Health Science Center at Houston, Houston, TX, [4]Department of Internal Medicine, Renal Diseases and Hypertension, McGovern Medical School The University of Texas Health Science Center at Houston, Houston, TX*

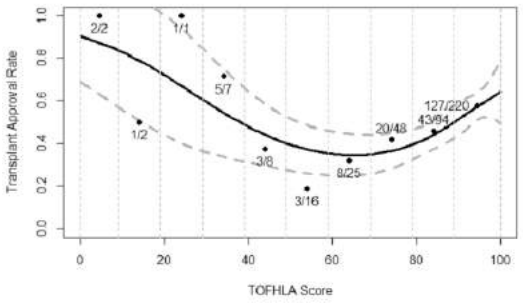
Purpose: Limited health literacy has long been associated with poor health outcomes in the general population, but there have been few studies investigating the association between health literacy and kidney transplant listing. The primary objective of this study was to determine if a patient's health literacy is associated with transplant listing.

Methods: We retrospectively reviewed 423 kidney transplant candidates who were prospectively administered the Test of Functional Health Literacy in Adults, a comprehensive numeracy and reading comprehension assessment, during their transplant evaluation. Health literacy scores, demographic, psychosocial, and medical variables were analyzed for correlation value with kidney transplant listing.

Results: Health literacy scores were found to highly correlate with transplant listing (p=0.003). Unexpectedly, a subset of patients (n=14 out of 36) who had health literacy scores < 59 was still able to obtain approval for listing. The probability of approval decreased when health literacy scores ranged from 0 to 59 and increased when health literacy scores varied between 60 to 100 (Figure 1). Multivariate analysis found transplant listing to also be associated with substance use (OR = 0.15, p < 0.001), ESRD etiology other than diabetes or hypertension (OR = 2.61, p < 0.001), pace of transplant evaluation (p < 0.001), and time on dialysis (p < 0.05). In contrast to other studies, neither race nor annual income were associated with transplant listing.

Conclusions: Health literacy is associated with kidney transplant listing, however patients with limited literacy are still able to be listed for transplant. The outcomes of this study suggest that health literacy should not be a barrier to listing, but rather an indicator for interventions that can promote access to transplantation. Further exploration on the impact of such interventions is important to reduce disparities in transplantation.

Figure 1. Estimated transplant approval rate and its 95% confidence intervals, as a function to TOFHLA score.



Note. Vertical dotted bins indicate the right limit of the frequency of score classes (0-9, 10-19, 20-29, 30-39, 40-49, 50-59, 60-69, 70-79, 80-89, 90-100). The points indicate the observed relative frequency of each class. For example, 2 out of 2 patients with TOFHLA score lower or equal to 9 were approved for transplant.

Abstract# 872

Experiential Expertise: What Can Patients and Donors Teach Us About Living Donation?

L. A. Davis[1], E. H. Wood[2], E. Ho[3], R. Pines[4], S. M. Advani[5], A. D. Waterman[2], *[1]DeSales University, Center Valley, PA, [2]UCLA David Geffen School of Medicine, Los Angeles, CA, [3]Terasaki Institute, Los Angeles, CA, [4]Santa Barbara Cottage Hospital, Santa Barbara, CA, [5]National Human Genome Research Institute, NIH, Bethesda, MD*

Purpose: While educational materials and discussions with medical professionals are factually sound, insight from actual living donors (LDs) and recipients (Rs) may offer unique, experiential expertise that many transplant professionals do not have. Here, we examined the lessons learned, recommendations, and critical advice provided by LDs and Rs to others considering living kidney donation (LKD) as part of the Living Donation Storytelling Project.
Methods: 160 storytellers (122 donors, 38 recipients) shared their experiences by online video platform. Storytellers were primarily White (55% White; 6% Black; 7% other; and 8% Hispanic) with a mean age of 50 years old for LDs and 48 years old for Rs. Two coders watched each video and coded dimensions of advice shared in response to the following prompts: "The best advice I could give someone else who is thinking about being a Living Donor is", and "My advice to others who need a kidney is...". Descriptive statistics were run to assess frequencies of themes across stories.
Results: Thematic analyses revealed 9 LD advice dimensions and 10 R advice dimensions. LDs advised potential donors to: Do research to learn about donation (30%); Get the support needed for post-donation care (28%); Go for it, donate a kidney (25%); Ask questions and get help with the donation process (21%); The choice is yours/listen to your heart when deciding whether to donate (20%); and Seek peer support from those who have donated (20%). Rs offered advice including: Get the word out/Share your need (58%); Don't lose hope (50%); Get the support you need for post-transplant care (32%); Do your research/stay informed (24%); and Be Proactive/Advocate for yourself (16%).
Conclusions: Both donors and recipients highlighted the positive impact of LKD on their overall life and encouraged participants to proceed with LKD. Key advice identified can help prospective LDs/Rs make informed choices, address key barriers, and seek help when needed. Although this type of advice cannot replace education, it does offer a source of peer support that can enhance the experience of donors and recipients, but also encourage autonomy and self-management post-transplant.

Abstract# 873

Ambient Air Pollution and Changes in Cognitive Function Among Kidney Transplant Recipients

Y. Feng[1], M. Jones[2], N. Chu[2], D. Segev[1], M. McAdams Demarco[1], *[1]Department of Surgery, Johns Hopkins School of Medicine, Baltimore, MD, [2]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Purpose: Although cognitive function among kidney failure patients improves after kidney transplant (KT), cognitive impairment is common and associated with worse post-KT outcomes. Particulate matter ($PM_{2.5}$), a common type of air pollution, is associated with dementia among general population; less is known about this effect among KT recipients. In this study, we seek to investigate the association between $PM_{2.5}$ and post-KT cognitive function trajectory among KT recipients.
Methods: We measured global cognitive function (3MS) among 637 KT recipients from a two-center, prospective cohort. We obtained the $PM_{2.5}$ data from NASA's Socioeconomic Data and Application Center Global Annual $PM_{2.5}$ Grids and linked the data to the participants using personal address and year of KT. The association between $PM_{2.5}$ and cognitive change post-KT was investigated using mixed model with random slope (time) and intercept (person) adjusting for age, sex, race/ethnicity, education and cognitive score prior to KT. We also explored the association separately by smoking status.
Results: Among 637 KT recipients, the median age at KT was 54.4 (IQR 43.1-64.0), 60.4% were male and 50.2% were non-Hispanic white. The median $PM_{2.5}$ exposure level was 10.1 $\mu g/m^3$ (IQR 9.4-11.1 $\mu g/m^3$). After adjustment, higher level of $PM_{2.5}$ exposure was not associated with steeper cognitive decline among KT recipients (Table 1). However, among ever smokers, those who had the 2nd (9.4-10.1 $\mu g/m^3$; slope=-1.34 points/year; $p_{interaction}$=0.003), 3rd (10.2-11.2$\mu g/m^3$; slope=-0.47 points/year; $p_{interaction}$=0.048) and 4th (11.2-16.5 $\mu g/m^3$; slope=-1.01 points/year; $p_{interaction}$=0.006) quartile of $PM_{2.5}$ exposure had steeper decline in cognitive function compared to those who had lowest quartile of $PM_{2.5}$ exposure (1.2-9.3 $\mu g/m^3$; slope=1.24 points/year).
Conclusions: Exposure to higher level of $PM_{2.5}$ was associated with steeper cognitive decline among KT recipients who were ever smokers, but not the overall study population. Our results suggested that air pollution might contribute to cognitive decline among some subgroups of KT recipients. Clinicians should consider performing cognitive screening tests for all transplant recipients who have a history of smoking and live in an area with high air pollution.

Association between PM2.5 and cognitive score trajectory by smoking status among 637 KT recipients

Abstract# 874

True Living Donation Experiences: A Thematic Analysis of Storytelling from Kidney Living Donors

E. Ho[1], E. H. Wood[2], R. Pines[3], L. A. Davis[4], S. M. Advani[5], A. D. Waterman[2], *[1]Terasaki Institute, Los Angeles, CA, [2]UCLA David Geffen School of Medicine, Los Angeles, CA, [3]Cottage Hospital, Santa Barbara, CA, [4]DeSales University, Center Valley, PA, [5]National Human Genome Research Institute (NIH), Bethesda, MD*

Purpose: Personal experiences of living donors (LDs) or recipients (Rs) can motivate more individuals to pursue living donor kidney transplant. After building

a library of 160 video stories of patients and LDs, we conducted thematic content analysis to identify common themes and the emotional changes experienced along the LD journey.
Methods: The 160 storytellers (76% LDs; 24% Rs) of diverse race/ethnicities (55% White; 6% Black; 7% other; and 8% Hispanic) recorded stories using open-ended prompts. Two coders watched each video and coded dimensions of the content participants shared including their emotions, barriers, motivations and personal experiences. Descriptive statistics were run to explore common themes and chi-squared test were run to compare differences based on participant's emotional status.
Results: Rs mostly reported they pursued a LD transplant due to its improved outcomes over deceased donation (84%), support from family (64%), and dissatisfaction feeling sick on dialysis (40%). A majority felt gratitude for the transplant (61%). LDs reported motivations to donate to improve someone's quality of life (42%), family support for donation (47%), concern for the donor's future health (38%), and gratitude and fulfillment received from donating (47%). As Rs & LDs progressed along the transplant journey their emotions shifted (Fig 1,2). Compared to before surgery, afterwards Rs were more likely to report feelings of happiness (21% vs 29%), relief (8% vs 21%), and hope (3% during kidney failure vs. 8% after surgery). Compared to before donation, LDs were more likely to report happiness (22% vs. 55%), relief (10% vs. 20%), and pride (3% vs 10%) afterwards.
Conclusions: LD stories captured through a digital library address the emotional and practical challenges they faced as well as the positive outcomes and gratitude they feel now. This realistic and reassuring library can be used to supplement traditional education about LD within medical encounters and through social media campaigns to generate interest in LD.

Abstract# 875

Association of Kidney Function with Patient Reported Outcomes After Kidney Transplantation

G. S. Kochar, S. A. Rega, I. D. Feurer, A. Dreher, H. Schaefer, D. Shaffer, R. C. Forbes, C. W. Pinson, B. P. Concepcion, *Nephrology, Vanderbilt University Medical Center, Nashville, TN*

Purpose: Our study aimed to determine the association of posttransplant eGFR with patient reported outcomes (PROs) and, specifically, the risk of reduced health-related quality of life (HRQoL) and increased symptoms of depression and anxiety with reduced eGFR.
Methods: PROs, assessed since 2002 in adult kidney transplant recipients at a single center, included the physical and mental summary components (PCS and MCS) of the Short Form 36 Health Survey, Centers for Epidemiologic Studies Depression Scale (CES-D), and Beck Anxiety Inventory (BAI). PROs were interpreted as being based on relevant norms (low if <35 for the PCS and MCS, and present if >9 or >7 for the CES-D and BAI). eGFR was classified as stages of chronic kidney disease (CKD): 1 or 2, 3a, 3b, and 4 or 5. The effects of eGFR on longitudinal PRO data were analyzed using multivariable mixed effects models that adjusted for age, donor type, time posttransplant, and prior transplantation. Using the most recent PRO observation per patient, multivariable logistic regression models determined the likelihood of substantively impaired PROs in relation to CKD stage.
Results: PRO data were reported by 2,116 adult kidney transplant recipients (mean age = 49.9 ± 13.1 years, male gender = 58%, re-transplantation rate = 5.5%, mean time from transplant to last (or only) observation = 74 ± 1.3 months). All covariable-adjusted longitudinal models (n >8,400 observations) demonstrated statistically significant associations between decreasing eGFR and lower PCS and MCS scores as well as greater symptom severity for depression and anxiety (all p <0.03). Substantively reduced PCS scores were 75% more likely at CKD stages 4 or 5 when compared to CKD stages 1 or 2. There was no effect of CKD stage on the likelihood of substantively reduced MCS. CKD stage 4 or 5, compared to CKD stage 1 or 2, carried a 65% greater likelihood of symptoms of depression and a 55% greater likelihood of symptoms of anxiety.

	Low Physical Quality of Life n = 2,116		Low Mental Quality of Life n = 2,116		Symptoms of Depression n = 1,809		Symptoms of Anxiety n = 1,890

Constant	0.080	< 0.001	0.154	< 0.001	0.679	0.082	0.404	0.002

Conclusions: Using a robust dataset of PROs, we found that kidney transplant recipients with CKD stages 4 and 5 are at increased risk for lower physical quality of life, and greater likelihood of having symptoms of depression and anxiety. Vigilant monitoring and earlier interventions by clinicians may be warranted in this vulnerable population.

Abstract# 876

Attitudes of Obese Kidney Transplant Candidates Towards Bariatric Surgery

C. LaVerne, V. Thompson, G. Aguiluz, P. DiCocco, J. Almario Alvarez, M. Spaggiari, I. Tang, I. Tzvetanov, E. Benedetti, *Surgery, University of Illinois Hospital & Health Sciences System, Chicago, IL*

Purpose: Obesity is an epidemic in the US and increasingly prevalent in kidney transplant candidates. Surgical weight-loss interventions are effective and reduce transplant-related complications. They also have a significant positive impact on the lifestyle and wellbeing of these patients. Special attention should be given to analyze what barriers or deterrents impede these patients from having bariatric surgery and design initiatives to overcome them.
Methods: A retrospective review was conducted in patients registered for kidney transplant evaluation from July 2017- June 2018. A chart review of the electronic medical record was conducted to collect demographics of the patients with criteria

(BMI > 35) for laparoscopic sleeve gastrectomy (LSG) and their responses to the offer of a bariatric referral with posterior follow up to identify patients that ultimately receive the procedure.

Results: A total of 422 patients were registered for kidney transplant and had nutrition evaluation completed, 119 (28.2%) met the eligibility requirements for bariatrics. Of those that were eligible, 73 (61.34%) accepted bariatric referral of which 32 (43.8%) initiated bariatric workup. Ultimately, 12 (10.1%) completed bariatric workup and underwent bariatric surgery, 1 patient had surgery in an affiliated hospital, details characterized in table and graphic.

Conclusions: Our obese candidates for kidney transplant have low bariatric surgery rates despite offering evaluations for LSG to all of them. Diet and exercise remain as their primary choice, which unfortunately has low success. Initiatives to increase acceptance of bariatric referral such as education and motivation should be considered for further investigation as a tool for success.

Abstract# 877

Current Opioid Utilization Practices of Kidney Transplant Centers in the United States: A National Survey of Institutional Practices

A. Lichvar[1], H. Kim[1], A. Ingemi[2], J. Jarrett[1], *[1]University of Illinois at Chicago, Chicago, IL, [2]Sentara Healthcare, Norfolk, VA*

Purpose: The opioid epidemic in the United States (US) and the known risks of opioid utilization highlight the need for better understanding of pain management around kidney transplantation. Although studies have been published describing efforts to minimize opioid therapy, clinical practices across the US remain unknown. The purpose of this survey study was to describe the utilization of opioids in the perioperative timeframe and upon discharge after kidney transplantation in the US.

Methods: This study was a cross-sectional survey of transplant pharmacists to evaluate the national landscape of opioid management with regards to pre-transplant candidacy, perioperative pain management, and post-transplant pain management. A 25-question survey was distributed to members of transplant pharmacy listservs within the US in March 2020.

Results: A total of 63/208 (30.3%) adult kidney transplant centers responded to the survey. Table 1 details survey demographics. The majority of institutions (84%) utilized opioids for first-line post-operative pain management in opioid-naïve patients. More than half of the centers (55%) did not differentiate post-operative pain regimen between opioid-naïve and opioid-tolerant patients. A total of 72.6% of institutions prescribed opioids upon discharge from transplant, and 10.8% of the institutions prescribed subsequent opioid analgesics in the outpatient setting. Figure 1 and Table 2 summarizes opioid utilization. Many patients were actively listed while on opioids (84.1%) or medications for opioid use disorder medications (MOUD) (58.2%) (Table 3). Many responders (82.7%) reported their institutions did not have a written protocol or policy for post-transplant pain management.

Conclusions: This survey highlights the existence of significant practice heterogeneity regarding opioid and MOUD utilization across kidney transplant programs in the US. Our survey highlights the opportunity transplant pharmacists have within the context of their multidisciplinary team to develop multimodal pain management strategies to minimize opioid use in kidney transplant candidates and recipients to continue to optimize patient care.

Table 1. Demographics Information

Demographic characteristic	n (%)
Type of hospital (n=47), n (%)	
Academic medical centers	40 (85.1%)
Non-academic medical centers	7 (14.9%)
Mean years of kidney transplant program, (SD) (n = 40)	35.5 (15.6)
Median number of transplants in year 2018-2019, (IQR) (n = 45)	150 (94.75-250)
UNOS Transplant Region (n = 44), n (%)	
Region 1	3 (6.8)

Abstract# 878

Covid-19-related Knowledge, Health Behaviors and Attitudes Towards Telemedicine and Emergency Visits in a Population of Kidney Transplant (KTx) Recipients

A. Lin, M. Saw-Aung, W. Yang, G. Udod, A. Imas, M. Markell, *SUNY Downstate Health Sciences University, Brooklyn, NY*

Purpose: We explored knowledge about COVID-19 and attitudes towards emergency care and telemedicine visits in a population of inner-city KTx pts.

Methods: A telephone survey was administered to a random sample of 33 KTx pts during July 2020, including questions regarding knowledge about COVID-19, health behaviors and attitudes regarding emergency and telemedicine visits. A COVID-19 knowledge score and COVID-19 concern score were calculated, with higher numbers indicating better knowledge and higher concern.

Results: Mean age was 58.3±11.1 yrs, with 19 (58%) men and 14 (42%) women with 23 (74%) Black, 4 (13%) Hispanic, 2 (7%) White, and 2 (7%) Other. 25 (78%) pts had not completed college. Five (15%) pts answered all questions correctly on COVID-19 knowledge, 28 (85%) answered at least 1 question incorrectly. 23 (74%) pts were afraid of COVID-19. 15 (46%) pts feared going to public places. 32 (97%) believed social distancing is important. Half were afraid of getting infected from a friend (18, 55%) or a family member (17, 52%). 27 (93%) reported feeling unsafe traveling on a plane. 6 (21%) pts reported reluctance to go to the ED if they had a medical emergency, including if they had a persistent low-grade fever (8, 28%), trouble breathing (2, 7%), or extreme belly pain (5, 17%). Pts who were afraid of going to the ED had higher scores for fear of COVID-19, fear of getting infection from a family member, fear of going to public places, and fear of traveling on an airplane ($p<0.05$). No associations were found between concerns about ED and COVID-19 knowledge. Pts who preferred telemedicine over in-person appointments were less likely to go the ED in an emergency (40% vs 89%, $p<0.05$) and scored higher overall on the COVID-19 knowledge (0.90±0.12 vs 0.76±0.13, $p<0.05$). No association was found for telemedicine preference and attitudes towards COVID-19. 100% (31) of pts reported: hand-washing with soap and water; using masks in crowds;

and isolating if flu-like symptoms were felt. Fewer avoided touching eyes, nose or mouth (94%); sanitized regularly surfaces at home (90%); avoided traveling for fun (87%), leaving their home (61%), or interacting in-person with someone who has COVID-19 (87%). No associations were found between behaviors and COVID-19 knowledge, telemedicine preference, or ED concerns.

Conclusions: In our population of KTx: 1. The majority of pts are knowledgeable but concerned about COVID-19 and follow public health guidelines. 2. Few pts answered all knowledge questions correctly. 3. Over a quarter would refuse to go to the ED if they had a persistent fever and many were concerned about the ED in general. 4. Pts who preferred telemedicine appointments were more knowledgeable about COVID-19 and less likely to go to the ED which may reflect their overall concern with COVID-19 exposure. 5. Education of our patients regarding actual risks of in-person or ED visits should be done to assure that they get care when needed.

Abstract# 879

Identifying the Needs of Kidney Transplant Recipients That Can be Addressed by a Web-based Self-management Program

D. Massierer[1], R. Sapir-Pichhadze[2], V. Bouchard[3], K. Dasgupta[2], N. Fernandez[4], D. da Costa[2], S. Ahmed[1], M. Fortin[5], R. Langevin[6], N. Mayo[1], T. Janaudis-Ferreira[1], *[1]Faculty of Medicine- School of Physical and Occupational Therapy, McGill University, Montreal, QC, Canada, [2]Centre for Outcomes Research and Evaluation (CORE), Research Institute of the McGill University Health Centre (RI-MUHC), Montreal, QC, Canada, [3]CIUSSS du Saguenay-Lac-Saint-Jean, Chicoutimi, QC, Canada, [4]Department of Family Medicine/Emergency Medicine, Université de Montreal, Montreal, QC, Canada, [5]Department of Medicine, Université de Montreal, Montreal, QC, Canada, [6]Canadian Donation and Transplantation Research Program (CDTRP), Edmonton, AB, Canada*

Purpose: Kidney transplantation improves the quality of life (QoL) of patients with end-stage renal disease, however, post-transplant recovery of physical health and other aspects of QoL remains well below age- and sex-matched norms. While members of the health care team are focused on optimizing the biological responses to transplant, patients may have few or no tools at their disposal to engage in behaviours that optimize QoL. We aimed to identify the needs of kidney transplant (KTx) recipients that are appropriate to address through self-management.

Methods: We used four strategies to identify areas of concern post-kidney transplantation: 1) assessment of affected areas post-transplant in 51 KTx recipients using the patient-generated index to identify areas of QoL that are affected post-transplant; 2) review of the outcome domains suggested by the Standardized Outcomes in Nephrology-Transplantation (SONG-Tx) international initiative; 3) review of the domains included in QoL questionnaires for KTx recipients and patients with chronic kidney disease and 4) focus groups and key informant interviews with patients, clinicians, and researchers. We linked the identified themes to the International Classification of Functioning's code list and created a saturation table to visualize the most common areas of concern.

Results: The most prevalent identified topics (identified in >3 strategies) were physical activity; fatigue; pain; sleep; mental health; nutrition; sexual function; side effects of medication; religion and spirituality; personal relationships/social life; and heart and kidney health.

Conclusions: KTx recipients have many areas of concern post-transplant that can be addressed through self-management. The next steps will include the development of a comprehensive, evidence- and experience-based self-management web-based program tailored to this patient population to improve their QoL.

Abstract# 880

Intersecting Disparities in Health Literacy Among Renal Patients Experiencing Transplant Barriers

C. W. Nonterah, K. Workman, S. Shah, *Psychology, University of Richmond, Richmond, VA*

Purpose: Recent data from the United States Renal Data System (USRDS, 2020) indicate that 131, 636 patients were diagnosed with end-stage renal disease (ESRD) in 2018, a 2.3% increase from the previous year (USRDS, 2020). Although kidney transplantation has been reported as the most effective form of renal replacement therapy, factors such as race, gender and socioeconomic status continue to affect patients' access to this treatment, resulting in disparities (McSorley et al., 2017; Nonterah & Gardiner, 2019; Patzer & Paston, 2013; Schold et al., 2011). Health literacy has been revealed as a contributing factor to reduced access to kidney transplantation, perpetuating disparities (Levy & Janke, 2016; Grubs et al., 2009). Yet, few studies have examined different disparities in health literacy and the ways in which they intersect to magnify a patient's barrier to transplantation. The current study sought fill a gap in the literature by examining disparities in race, gender and income associated with health literacy as well as potential intersections between these disparities.

Methods: Participants consisted of ESRD adult patients (N=181) with a mean age of 43.50 (SD =9.50) who reported experiencing transplant barriers. These participants were recruited from a transplant center in the Southeastern region of the US. Participants took a survey which consisted of demographic questions and all nine scales of the Health Literacy Questionnaire.

Results: Multiple regression analyses were conducted to examine the associations between race, gender and income with health literacy. Results revealed a significant relationship between gender and feeling understood and supported by providers, having enough information to manage health, actively managing health, and appraisal of health information. Income was also significantly associated with these dimensions of health literacy. When gender, income, and the multiple effects of gender and income were placed in the model, the results revealed a significant regression equation between gender and feeling understood by providers, β =-.44 , t (175) = -2.306 , p = .022 well as the combined effect of gender and having a household income between $40,000-$79,999, β =.34, t (175) = 2.036 , p = .043.

Conclusions: Overall, the findings from the current study suggest that gender differences contributed the most to the differences in health literacy with women reporting low health literacy relative to the men in our sample. Men in the middle-income range reported higher levels of health literacy. These results provide some evidence for additional research in this area, especially research that examines the multiple effects of different factors associated with disparities in health literacy.

Abstract# 881

Understanding Early Transplant Preparation: CKD 3-5 Patients' Transplant Knowledge and Actions at Kaiser Permanente Southern California

R. Pines[1], S. H. Kawakita[2], G. H. Kim[3], O. Ranasinghe[4], B. Mittman[5], B. Dub[5], H. Wilhalme[3], A. D. Waterman[3], *[1]Santa Barbara Cottage Hospital, Santa Barbara, CA, [2]Terasaki Institute, Los Angeles, CA, [3]UCLA David Geffen School of Medicine, Los Angeles, CA, [4]Outbreak Management Branch, Los Angeles County Department of Public Health, Los Angeles, CA, [5]Research and Evaluation, Kaiser Permanente, Pasadena, CA*

Purpose: While consensus exists on the need to educate patients earlier about transplant, delays in education persist, leaving patients insufficient time to make optimal renal replacement (RRT) decisions. This study assessed levels of transplant-related knowledge and actions by kidney patients varying by CKD stage and primary language spoken.

Methods: 971 patients at Kaiser Permanente Southern California were assessed about their knowledge of CKD symptoms (6-items, e.g., increased fatigue is a CKD symptom) and transplant (20-items, e.g., patients can live longer with a transplant than on dialysis). They also reported whether they had already taken 25 possible RRT actions divided into three groups: (1) learning actions, (2) making informed decisions about RRT, and (3) pursuing transplant. Patients varied by CKD Stage [3 (41.2%); 4 (34.4%); 5 (24.4%)], race/ethnicity, and primary language [Spanish-speaking Hispanic (28%), White (22%), English-speaking Hispanic (22%), Black (18%), and Asian (10%)].

Results: Overall, patients correctly answered 58% of CKD symptoms items, and 20% of transplant knowledge items. Most patients had taken few steps to learn more (median: 0 of 5 steps), make informed decisions about RRT options (median: 2 of 6 steps), and pursue transplant (median: 0 of 6 steps). Earlier CKD stage and Spanish-speaking patients had poorer CKD symptom and transplant knowledge and took fewer action steps overall (Table).

Conclusions: Patients in earlier CKD stages and Spanish-speakers are less knowledgeable and less likely to take transplant-related actions, however, all patients need

greater support with RRT decision-making and pursuit of transplant. Educational interventions that engage patients earlier in their CKD progression may increase informed decision-making and pursuit of LDKT.

Table. Variation in Transplant Knowledge and Actions

	CKD Stage			Primary Language Spoken	
	3	4	5	English	Spanish
Knowledge (% Correct)					
CKD Symptoms**	50.0%	58.3%	75.0%	66.7%	50.0%
Transplant Knowledge**	16.0%	20.0%	24.0%	20.0%	14.0%
Actions (Median Completed)					
Learn about RRT**	0	1	2	1	0
Make Informed Decisions about RRT**	1	3	4	3	2
Pursue Transplant*	0	0	1	0	0

Abstract# 882

Patients' Perceptions of Kidney Transplant Failure and Transitioning to Dialysis

E. Ramos[1], C. Gu[2], C. Hanson[2], K. Abdel-Kader[3], K. Bonnet[2], D. Schlundt[2], E. Gordon[4], B. P. Concepcion[3], *[1]Cleveland Clinic Foundation, Cleveland, OH, [2]Vanderbilt University, Nashville, TN, [3]Vanderbilt University Medical Center, Nashville, TN, [4]Northwestern University, Chicago, IL*

Purpose: Approximately 5,000 US kidney transplant recipients return to dialysis each year due to allograft failure. Understanding how kidney allograft failure and transitioning to chronic dialysis affects patients emotionally, and their perceptions of the care that they received during the transition can identify avenues for improved care for patients.

Methods: Semi-structured interviews were conducted at a single center with 29 adult patients who had developed allograft failure and returned to dialysis within the last 5 years. Thematic analysis was used to code the transcripts and identify emerging themes.

Results: Five themes emerged about patients' transition from allograft failure to chronic dialysis: 1) Patient context: the acuity of allograft decline, symptoms that accompanied decline, frequency of interactions with the heath care system, and personal understanding of reasons for graft failure varied among patients. 2) Impact on quality of life: allograft failure had a negative impact on quality of life such as interference with daily life activities, and loss of independence. (3) Emotional response: patients reported feelings of shock, sadness, hopelessness, frustration, disappointment and anxiety, (4) Coping: they felt well-supported emotionally by their family, friends and providers. They expressed desire that the diagnosis of allograft failure be delivered with compassion along with a thorough discussion of the cause of allograft loss. They expressed appreciation when this occurred. (5) Health system context: mental health resources were considered helpful. Poor care coordination after allograft failure leading to confusion in immunosuppression medication tapering and infectious complications as well as limitations in insurance coverage were perceived as harmful.

Conclusions: Kidney allograft failure is a devastating experience to patients and their families. Ensuring compassionate communication between patients and providers, readily available mental health resources and care coordination, and social work support to navigate health insurance challenges during the transition from allograft failure to chronic dialysis may improve the patient experience.

Abstract# 883

Impact of Pre- and Post-transplant Outcomes on Patient-reported Outcomes in a Prospective Multicenter Trial in Kidney Transplantation

J. M. Rohan[1], J. P. Leone[2], E. Woodle[3], D. Kaufman[4], A. R. Shields[3], A. Wiseman[5], A. J. Matas[6], P. West-Thielke[7], E. King[3], R. R. Alloway[3], *[1]Children's Hospital Richmond VCU, Richmond, VA, [2]Tampa General, Tampa, FL, [3]U Cincinnati, Cincinnati, OH, [4]U Wisconsin, Madison, WI, [5]Centura Transplant, Denver, CO, [6]U Minnesota, Minneapolis, MN, [7]UIC, Chicago, IL*

Purpose: BEST Trial (**B**elatacept-based **E**arly **S**teroid-withdrawal **T**rial) compared belatacept (BELA)-based early steroid withdrawal (ESW) regimens with a tacrolimus (TAC)-based ESW regimen across 2years. CNI free/ESW bela groups revealed improved patient-reported outcomes (PROs) in kidney transplant (KTx) patients (pts). GI distress in TAC group increased across 2-years. Neurologic, GI, and mobility symptoms were reported less frequently in BELA groups. Previous trials did not examine predictive models investigating longitudinal differences in PROs between BELA- and TAC-groups. We attempt to determine if clinically relevant pre- and post-transplant outcomes [e.g., chronic dialysis vs. pre-emptive, acute rejection, diabetes (preexisting, new onset diabetes after transplant (NODAT), death, death censored graft loss (DCGL), and eGFR<45] predicted worse PROs over two years

Methods: This longitudinal, multisite study was conducted across 8 sites. All pts received mycophenolate and 5 days of steroids. Pts were randomized to 3 groups: alem+BELA, r-ATG+BELA, r-ATG+TAC. Pts completed 2 PRO measures at baseline, 1-, and 2-years (MEMPHIS, MTSOSD-59R). Intent to treat analyses (n=316) using a multivariate analysis (MVA) framework examined pre- and post-transplant outcomes, randomization assignment, time since KTx, gender, and race

Results: MVA (Table 1) indicated pts receiving pre-emptive transplant reported worse PROs across 2-years. Preexisting diabetes and NODAT predicted worse PROs over time. Death, DCGL, rejection, and eGFR<45 was not predictive of PROs with exception of mobility; those with eGFR<45 reported worse mobility. Controlling for gender, race, and time post KTx, medication regimen only significantly influenced the relationship between PROs in pts who developed NODAT and received TAC; these pts reported significantly worse miscellaneous symptoms than BELA-treated pts.

Conclusions: Predictive models indicated pre-emptive transplant, preexisting diabetes, NODAT, and eGFR<45 significantly predicted worse PROs. Rejection did not predict PROs. TAC pts with NODAT reported worse miscellaneous symptoms. These findings support utilization of PROs in drug trials to highlight the value of regimens with lower NODAT and improved eGFR.***Table 1. Multivariate Analyses for Predictive Models of PROs***

Abstract# 884

Validation of PROMIS Anxiety Computer Adaptive Test in Solid Organ Transplant Recipients

M. Saqib, M. Yang, F. Jamal, S. Aghamohammadi, G. Ahmadzadeh, M. Hamid, V. Shah, N. Jayakumar, M. Novak, I. Mucsi, *University Health Network, Toronto, ON, Canada*

Purpose: To assess the validity and reliability of the PROMIS Anxiety item bank administered using Computer Adaptive Test (PROMIS-A CAT) in patients who received solid organ transplant.

Methods: A cross-sectional convenience sample of adult kidney (KTR), kidney-pancreas (KPTR), and liver (LTR) transplant recipients completed PROMIS-A CAT, General Anxiety Disorder-7 (GAD7), Patient Health Questionnaire (PHQ-9), Kidney/Liver Disease Quality of Life-36 (KDQoL/LDQoL), Edmonton Symptom Assessment System Revised (ESASr) and EuroQoL EQ-5D (EQ5D) questionnaires on an electronic data capture platform. Sociodemographic and clinical variables were collected from medical records. A sub-group of participants was asked to retake PROMIS-A CAT within 14 days; test-retest reliability was assessed using intraclass correlation coefficient (ICC). Construct validity was confirmed using correlation between PROMIS-A CAT scores and scores on questionnaires measuring similar constructs, and also using "known group" comparisons. Discrimination of PROMIS-A CAT was assessed using receiver operating characteristic (ROC) analysis and an established cut-off on GAD7 (≥10) for moderate/severe anxiety.

Results: A cross-sectional, convenience sample of 431 participants were recruited (mean [SD] age: 53 [14] years, 65% male, 68% Caucasian). 251 (58%) were KTRs, 18 (4%) were KPTRs and 162 (38%) were LTRs. 13% reported moderate/severe anxiety (GAD7 score ≥10). Mean (SD) PROMIS-A CAT score was 52.4 (8.5); participants answered an average of 5 questions. PROMIS-A CAT showed good test-retest reliability (ICC: 0.802). PROMIS-A CAT showed moderate correlation with GAD7 (rho=0.63, p<0.001), PHQ9 (rho=0.60, p<0.001), and KDQoL/LDQoL SF-12 Mental Health Composite Score (rho=-0.56, p<0.001). In "known group" comparisons, mean (SD) PROMIS-A CAT scores were significantly higher for females compared to males (54 [7], 51 [9]; p<0.001) and for albumin (g/L) ≤35 compared to ≥40 (56 [8], 52 [8]; p=0.024). PROMIS-A CAT scores were also significantly higher for patients who reported ≥30 score on ESASr compared to <30 (59 [8], 51 [8]; p<0.001), and for patients who reported moderate/severe compared to no/slight anxiety/depression on EQ5D (56 [9], 51 [8]; p<0.001). PROMIS-A-CAT had excellent discrimination with an area under of the ROC curve of 0.87 (95% CI: 0.82, 0.93).

Conclusions: These results provide support the validity and reliability of PROMIS-A CAT among patients who received a solid organ transplant and support its use in research and clinical care.

Abstract# 885

Transplant Decision Making Concerns for Asian Patients with End-Stage Kidney Disease

N. Singh[1], A. Wasim[1], G. Chawla[1], F. Jamil[1], M. Hamid[1], R. Siddiqui[1], E. Lui[1], N. El-Dassouki[1], M. Novak[1], A. D. Waterman[2], I. Mucsi[1], *[1]University Health Network, Toronto, ON, Canada, [2]David Geffen School of Medicine, UCLA, Los Angeles, CA*

Purpose: Compared to White Canadians, Asian Canadians with end stage kidney disease (ESKD) are less likely to receive living donor kidney transplant (LDKT). We explored factors associated with kidney transplant (KT) decision-making, specifically the weight patients give to perceived pros and cons for KT decisions.

Methods: Using the Transplant Decisional Balance survey, patients rated the importance of perceived pros and cons to KT decision-making from 1-5 ("not important"-"extremely important"). We surveyed a cross-sectional convenience sample of adults with ESKD in Toronto. Ethnicity (White, Asian [South and East], other) was self-identified. Individual ratings of pro/con items were summed to yield LDKT and deceased donor KT (DDKT) pro/con scores. Individual scale items were also examined: dichotomized (not/slightly/moderately vs very/extremely important) and their independent association with ethnicity was analyzed in multivariable logistic regression.

Results: Among 590 participants (mean[SD] age 57[13] years, 62% male), 24% were Asian, and 42% were White. Asians were less likely to have incomes >$30K/year (52% vs 71%, p<0.001) and were more likely to be immigrants (75% vs 27%, p<0.001) compared to Whites. The summed LDKT scores and DDKT pro scores were similar between the groups. However, Asian participants rated perceived DDKT con scores (median [IQR]: 12[7,16] vs 9[5,13]; p=0.025) higher than Whites. In univariable analysis, compared to White participants, Asian participants were more likely to indicate that perceived "pain from surgery" (OR, 2.20 [95% CI: 1.30, 3.37]), "taking many medications post-transplant" (OR, 2.18 [95% CI: 1.40, 3.38]), and "if transplant failed it would be a lot of work/pain for nothing" (OR, 3.02 [95% CI: 1.75, 5.21) were very/extremely important to their transplant decision. These associations remained significant after adjusting for sociodemographic variables, comorbidity, and transplant knowledge at onset, (OR, 2.16 [95% CI: 1.23, 3.78]), (OR, 2.22 [95% CI: 1.37, 3.60]), (OR, 3.30 [95% CI: 1.83, 5.95], respectively).

Conclusions: Anticipated pain, concerns about the quantity of post-transplant medications and potential unsuccessful transplant weighs into KT decision making among Asian Canadians with ESKD more than for White Canadians. Further qualitative research is needed to better understand the reasons for these ethnicity-specific differences in decision making.

Abstract# 886

Information-Seeking Behavior During Covid-19: Opportunities for Communication and Care Transition Improvements

S. H. Advani[1], S. M. Advani[2], Y. A. Iraheta[3], A. Murillo[4], H. A. Gritsch[3], A. D. Waterman[3], *[1]Terasaki Institute, Bethesda, MD, [2]National Human Genome Research Institute, Bethesda, MD, [3]UCLA, Los Angeles, CA, [4]Terasaki Institute, Los Angeles, CA*

Purpose: To learn more about how at-risk dialysis and transplant patients sought health information during COVID-19 and what was most helpful, we conducted a mixed-methods study of people contacting a telephone COVID-19 Kidney & Transplant Listening Center.

Methods: Participants answered a survey in English or Spanish, including open-ended and closed-item questions assessing the types of COVID-19 related care transition experiences they had, their telehealth comfort using the Unified Theory of Acceptance and Use of Technology (UTAUT), what types of questions they had, and information-seeking behavior. Thematic analysis was conducted and descriptive statistics were run for quantitative items.

Results: 111 participants completed the survey. They were primarily English-speakers (84.85%) and of Hispanic/Latino (26.13%), White (24.35%) Black (23.42%) and Asian (23.42%) race/ethnicities, with an average age of 50 years, and with either a bachelor's degree or higher (51.96%).

Participants consumed health information at least two times weekly via internet (56.57%), television (40.57%), or print sources (31.13%). They were more likely to learn about health issues from news media (78.38%) than healthcare institutions (57.66%). Nearly 70% talked about health issues with family/friends twice a week. Most patients had experienced a change in care during the pandemic (66.3%), and 44.14% said they had postponed a medical visit. Questions that were raised related to their vaccine priority, higher risk of death as a transplant patient during COVID-19, and how to stay safe at dialysis.

A third (28.57%) agreed they could not find specific health information they needed. Participants with high school (HS) degrees or less were less likely to agree that the amount of information they had to make health choices was helpful (P=0.002).

Generally, participants believed they had the necessary resources (95.23%) and knowledge (93.27%) to access telehealth, however, those with HS degrees (p=0.002) or Medicare (P<0.001) were less confident. Finally, they reported that a website with FAQs answered by experts (68.47%) or a live chat for questions (67.57%) would be helpful.

Conclusions: During the pandemic, patients engaged in high levels of health information seeking weekly, often from media sources versus healthcare institutions that have more accurate kidney-related recommendations.

Kidney

Kidney: Acute Cellular Rejection

Abstract# 887

How Should Acute T-Cell Mediated Rejection of Kidney Transplants be Treated?

F. Aziz[1], S. Parajuli[2], N. Garg[2], M. Mohamed[2], A. Djamali[2], D. Mandelbrot[2], *[1]University of Wisconsin, Madison, WI, [2]University of Wisconsin, Verona, WI*

Purpose: Many guidelines suggest treating acute T-cell mediated rejection (TCMR) of kidney allografts that is Banff grade I with steroids alone and Banff grade II with steroids plus anti-thymocyte globulin (ATG).

Methods: We reviewed the kidney function and histological outcomes after treatment of 163 first episodes of biopsy-proven TCMR between 1/1/2015 and 07/31/2020. Patients with any component of antibody mediated rejection were excluded. Histological responses were defined: complete response (CR) as no residual rejection, partial response (PR) as improved Banff grade but persistent rejection, and no response (NR) as no change in Banff grade. Kidney function responses were defined: CR as eGFR returned to within 5ml/min/m2 of baseline eGFR, PR as improvement of eGFR by more than 5ml/min/m2 from nadir eGFR, and NR as eGFR staying above a value 5ml/min/m2 lower than peak eGFR.

Results: Of 163 kidney recipients with TCMR, 146 were treated with steroid pulse alone. 83% of patients with borderline rejection, 82.5% with grade 1A, 67% with grade 1B, and 50% with grade IIA had a histological CR or PR to treatment with steroids alone. Seventeen patients were treated with steroids plus ATG. The CR or PR response rate was 100% with grade 1A, 75% with grade 1B, 100% with grade IIA, and 57% with grade IIB. In patients with CR histologically, 58% had CR in their eGFR, but 18% had NR in eGFR. Of patients with PR histologically, 33% had CR, 42% had PR and 25% had NR based on eGFR. Of the 34 patients without CR histologically on the first biopsy who underwent additional treatment with steroids, 26 achieved CR. Histological and kidney function response to treatment was associated with better graft outcomes compared to patients with PR or NR to treatment (p=0.03 & 0.01 respectively). Multivariate analyses showed that higher grade of rejection was associated with worse long-term graft outcomes (HR=1.5, p=0.004, 95%CI 1.13 to 1.99). Histological response and kidney function response to treatment was associated with improved graft outcomes (HR=0.64, p=0.04, 95%CI 0.3961 to 1.0541; HR=0.5, p=0.003, 95%CI 0.315 to 0.84 respectively).

Conclusions: We demonstrate that responses based on kidney function alone do not correlate well with histological responses. Some patients with CR in eGFR have only PR histologically, and benefit from additional treatment. Others with NR in eGFR have CR histologically, and do not require additional treatment. These findings support the utility of protocol follow-up biopsies after treatment for TCMR to guide further treatment.

Correlation between histological and kidney function response to the treatment

Histological response to the treatment	Response to the treatment based on eGFR		
	Complete response (n=79)	Partial response (n=42)	No response (n=42)
Complete response (N=129)	75/129 = 58%	31/129 = 24%	23/129 = 18%
Partial response (N=12)	4/12 = 33%	5/12 = 42%	3/12 = 25%
No response (N=22)	0/22	6/22 = 27%	16/22 = 73%

Abstract# 888

Kidney Transplant Survival After Borderline Rejection in the Setting of Denovo Dsa Formation

A. P. Bregman[1], S. Jackson[2], S. Riad[1], *[1]Department of Nephrology, University of Minnesota, Minneapolis, MN, [2]Biostatistics, M-Health Fairview Analytics, Minneapolis, MN*

Purpose: The significance of borderline cellular rejection has been questioned in the past. Data on borderline rejection with deNovo DSA (dnDSA) formation is limited. We sought to evaluate the outcome of borderline rejection detected after the appearance of dnDSA.

Methods: Retrospective review of adult primary kidney alone transplant recipients of either living or deceased donor at our center since 2000 who received depletional induction with thymoglobulin 6mg/kg and early steroid withdrawal that survived >1 month with allograft, found to have dnDSA and had kidney transplant biopsy within 2 months of dnDSA discovery. We grouped recipients by rejection grade into 3 groups: no rejection (n=60), borderline rejection (n=24) and definitive rejection group defined as rejection other than borderline (BPAR) (n=46). Kaplan-Meier curves were generated for death censored graft Survival (DCGS) by rejection grade with follow up censored at 5-years post dnDSA discovery.We used Cox proportional hazard model to examine the association between rejection grade and death censored graft survival. Model was adjusted for HLA-MM, Race, BMI, donor type and age.

Results: Baseline characteristics are listed in Table 1. Greater than 70% of patients had a subtherapeutic CNI level in the month preceding biopsy. In the Kaplan-Meier analysis, death censored graft survival was not statistically different by rejection grade among recipients with dnDSA formation (Figure 1). In the multivariable Cox proportional hazards model for DCGS, compared to the no rejection group, borderline rejection was not found to be a significant predictor of graft loss [HR 2.9, 95% C.I. (0.48, 17.2) p=0.25], while BPAR was associated with a 5.7-fold increased risk of graft loss among dnDSA forming recipients [HR 5.7, 95% C.I. (1.756, 18.415), p=0.004].

Conclusions: In this small sample of transplant recipients with dnDSA formation who underwent diagnostic biopsy, borderline rejection was not a significant predictor of graft loss as compared to recipient without rejection.

Abstract# 889

Impact of Induction Immunosuppression Selection on Clinical Outcomes in Kidney Transplant Recipients During the COVID-19 Pandemic in New York City

K. Khalil, S. Jonchhe, J. Stern, T. C. Lewis, N. Alnazari, B. Lonze, Z. Stewart Lewis, N. Ali, *Transplant Institute, NYU Langone Health, New York, NY*

Purpose: As an early epicenter in the coronavirus pandemic, our center modified induction immunosuppression strategies for transplantation. We sought to determine if changes in induction immunosuppression secondary to the COVID-19 pandemic impacted the incidence of acute rejection.

Methods: Adult kidney transplant recipients at NYU Langone Health between 09/2019 and 08/2020 were retrospectively identified. Patients who received a multi-organ transplant or whose induction regimen was changed due to clinical course were excluded. Patients transplanted before and after 3/17/2020 were grouped as pre-pandemic (PRE) and post-pandemic (POST), respectively, based on temporary interruption of transplantation. Induction immunosuppression discordance was identified by blind adjudication from a standard protocol. Reduced induction agent use (basiliximab given when pre-pandemic protocol indicated rabbit anti-thymocyte globulin (rATG)) was compared between groups using a Chi-square test. Biopsy-proven acute rejection (BPAR) and the incidence of rejection was compared using a Poisson regression model.

Results: 203 kidney transplant recipients were retrospectively identified. 38 patients were excluded, leaving 165 patients for analysis. Median patient age was 57 years, 67% were male, and diabetes mellitus (35%) was the most common cause of renal disease. Discordance from protocol induction agent was 16% in the PRE group and 28% in the POST group (p=0.06). More patients received reduced induction with basiliximab in lieu of rATG in the POST group than the PRE group (26% vs. 7%, p=0.001). BPAR occurred in 5 PRE (5%) and 6 POST (11%) patients (p=0.19). The incidence of rejection was 0.13 and 0.75 rejection episodes/1,000-patient days for the PRE and POST groups, respectively; this was significantly different between the 2 time periods (unadjusted IRR 5.69, 95% CI 1.74-18.6, p=0.004).

Conclusions: More patients received reduced induction immunosuppression driven by the COVID-19 pandemic concerns. These COVID-related changes in immunosuppression may have contributed to a trend in increased acute rejection in a preliminary analysis.

Abstract# 890

Impact of Treatment of Subclinical Rejection at 2 Weeks After Kidney Transplantation, Compared by 1 Year Histologic Outcomes

O. Lee[1], K. Lee[1], J. Park[1], J. Lee[2], G. Kwon[3], K. Kim[4], *[1]Surgery, Samsung Medical Center, Seoul, Korea, Republic of, [2]Medicine, Samsung Medical Center, Seoul, Korea, Republic of, [3]Pathology, Samsung Medical Center, Seoul, Korea, Republic of, [4]Biostatistics, Samsung Medical Center, Seoul, Korea, Republic of*

Purpose: Subclinical rejection (SCR) is associated with chronic allograft nephropathy, which is the most common cause of allograft failure in kidney transplantation (KT). Therefore, early detection and treatment of subclinical rejection through protocol biopsy can reduces the incidence of chronic allograft nephropathy and the improvement of graft survival. This study aims to evaluate the effective early detection role of routine protocol biopsy by comparing the pathologic outcome.
Methods: We retrospectively analyzed 914 kidney transplantation recipients in our center between August 2012 and December 2018. Of these, pediatric cases, re-transplantations and multi-organ transplantation, cyclosporine and azathioprine users, patients who were not underwent protocol biopsy, and diagnosed rejection but not treated patients were excluded. Finally, a total of 624 adult patients who were underwent protocol biopsy at post KT 2 weeks and 1 year were analyzed.
Results: After propensity score matching, patients were divided into two groups, 2-week protocol biopsy proven normal group (n=256) and rejection group (n=96). Before propensity matching, normal group was significant higher recipient age and ABO incompatible KT, rejection group was higher HLA II mismatch and proportion of deceased donor KT, the difference was corrected through matching. Rejection group showed no significant difference from normal group in the tendency of graft function (eGFR), and Kaplan-Meire curve also shown that in graft survival. In the pathologic outcomes between two groups and two periods, the pathological differences between two groups showed a decrease between two periods.
Conclusions: Subclinical rejection treatment through protocol biopsy can contribute to maintenance of graft function and improvement of pathologic change.

Abstract# 891

Continuous 24-Hour Antithymocyte Globulin (ATG) for Renal Allograft Rejection: Results of a Randomized Controlled Trial

S. J. Patel, A. Rogers, S. Kuten, R. Knight, E. Graviss, D. Nguyen, T. Ellimuttil, I. Agboli, L. Gaber, A. Gaber, *Houston Methodist Hospital, Houston, TX*

Purpose: For acute renal allograft rejection (AR), ATG is generally administered in the inpatient setting because of the need for intravenous access, patient monitoring, and daily administration. Herein, we report the initial outcomes of a trial evaluating the feasibility of a 24-hour ATG infusion to reduce inpatient length of stay (LOS).
Methods: Patients requiring ATG (Thymoglobulin®) for treatment of biopsy-proven AR were randomized 1:1 to receive either a 24-hour continuous infusion of ATG 6 mg/kg (24-hour arm) or 4 daily infusions of 1.5 mg/kg, each over 6 hours (Daily arm). Pre-medications were methylprednisolone, diphenhydramine and acetaminophen administered every 6 hours starting prior to the infusion in the 24-hour group and prior to each daily infusion in the Daily group. Patients with concomitant antibody mediated rejection (AMR) were excluded. The primary endpoint of the study was LOS defined as the number of overnight stays post-ATG initiation. Secondary endpoints included side effects occurring during the infusions, rejection resolution

(defined as absence of AR on repeat biopsy 2-3 weeks post-treatment), 30-day readmissions, infections, renal function, and hematologic laboratory values through 6 months post-treatment.

Results: To date, 30/30 patients have been randomized, all have reached the primary endpoint analysis and 24/30 have completed 6 months of follow-up. One 24-hour patient was diagnosed with AMR after enrollment and required an extended LOS for treatment but was included in the current analysis. Baseline characteristics were similar between groups (Table 1). 24-hour ATG was discontinued after 75% of the infusion in one patient due to nausea and anxiety, and temporarily held in another patient due to chills and fatigue. All other patients tolerated the infusion well. Mean infusion time for the 24-hour group was 25±5.2 hours. Mean LOS following ATG initiation was 2.3±1.4 days for the 24-hour group vs. 3.7±1.0 days for the Daily group (p=0.004, Table 2). No differences were seen in vital signs or adverse effects between 24-hour and Daily infusion groups, nor were there significant differences in hematologic parameters, renal function and other post-treatment outcomes through 6 months (Table 2). Graft loss occurred a week after ATG initiation in one 24-hour patient who presented with acute and chronic rejection 7.7 years post-transplant.

Conclusions: Continuous infusion ATG over 24 hours for AR is feasible and significantly reduces inpatient LOS. Complete follow-up on the remaining patients is ongoing.

Abstract# 892

Dosing Weight of Rabbit Antithymocyte Globulin and Outcomes Among Kidney Transplant Patients Treated for Rejection

C. Patton, K. Cunningham, C. D'Agostino, A. Novak, M. Kapugi, K. Lang, C. Kane, *Pharmacy, Northwestern Memorial Hospital, Chicago, IL*

Purpose: Rabbit antithymocyte globulin (rATG) is FDA approved for kidney transplant induction therapy and treatment of T-cell mediated rejection (TCMR). While prior studies comparing dosing weight strategies for induction therapy have illustrated similar outcomes between IBW and TBW, there is no data comparing dosing strategies for treatment of rejection. This study was designed to identify the impact of dosing weight on outcomes in kidney transplant recipients treated for TCMR.

Methods: This was a single-center, retrospective review of kidney transplant recipients who received at least one dose of rATG for the treatment of TCMR between 2014 and 2019 at Northwestern Memorial Hospital. Patients were excluded if they were multi-organ transplant recipients < 18 years of age. Patients were divided into groups based on cumulative rATG exposure of > 7.5 mg/kg or ≤ 7.5 mg/kg according to IBW. The primary outcome was the change in serum creatinine (SCr) from the first dose of rATG to one month after the final dose. Six-month secondary outcomes included graft survival, hospital readmissions, and infection rate. In addition, we evaluated the incidence of leukopenia (WBC < 3.5 K/UL), neutropenia (ANC < 1.5 K/UL), and thrombocytopenia (PLT < 150 K/UL) after the final rATG dose.

Results: 44 patients who received rATG for treatment of TCMR were included, with 16 patients receiving > 7.5 mg/kg and 28 patients receiving ≤ 7.5 mg/kg. BMI was significantly greater in the group receiving > 7.5 mg/kg group (31.3 vs 25.2 kg/m^2, p=0.008), with other baseline characteristics similar between groups. There was no difference between groups in the percent change in SCr one month after rATG therapy (-14.3% vs -16.9% p=0.8). Graft failure at six months was numerically higher in the >7.5 mg/kg group; however, this was not a statistically significant finding (31.3% vs 17.9%, p=0.46). There were two fungal infections identified, Cryptococcal meningitis in the > 7.5 mg/kg group and pulmonary blastomycosis in the ≤ 7.5 mg/kg group. One patient died from septic shock in the >7.5 mg/kg group. Overall, the infection rate was similar between treatment groups (43.8% vs 25.0%, p=0.31). No difference was identified for other secondary outcomes (Table 1).

Conclusions: There was no significant difference in percent change in SCr between dosing groups in kidney transplant patients treated for rejection. There was a trend towards a decreased risk of infectious complications, hospital readmissions, and graft failure in the ≤ 7.5 mg/kg dosing group. Larger, prospective studies are needed to confirm these findings.

Table 1: Baseline Characteristics and Outcomes

	≤ 7.5 mg/kg rATG, IBW (n=28)	> 7.5 mg/kg rATG, IBW (n=16)	P-value
Baseline Characteristics			
Age (years ± SD)	37 ± 17	40 ± 15	0.61
Male gender	16 (57.1%)	10 (62.5%)	0.76
BMI (kg/m^2 ± SD)	25.5 ± 6.6	31.3 ± 6.5	**0.008**
TBW (kg ± SD)	73.8 ± 26.5	96.9 ± 26.7	**0.008**
TCMR ≥ Banff 2A	10 (35.7%)	9 (56.3%)	0.22
Outcomes			
Percent change in SCr	-16.9%	-14.3%	0.8
Graft failure	5 (17.9%)	5 (31.3%)	0.46
Hospital readmissions	10 (35.7%)	9 (56.3%)	0.22
Infection	7 (25.0%)	7 (43.8%)	0.31
Leukopenia*	4 (14.3%)	3 (23.1%)	0.67
Neutropenia*	0 (0%)	1 (6.3%)	0.37
Thrombocytopenia*	5 (23.8%)	4 (36.4%)	0.68

SD – standard deviation; IBW – ideal body weight; TBW – total body weight; rATG – rabbit antithymocyte globulin; BMI – body mass index; TCMR – T-cell mediated rejection; SCr – serum creatinine
*Patients were excluded from this outcome if they had leukopenia, neutropenia, or thrombocytopenia prior to rATG administration.

Abstract# 893

Role of Serial Donor Derived Cell-Free DNA Monitoring in Kidney Transplant Recipients

A. X. Wang, C. R. Lenihan, *Nephrology, Stanford University School of Medicine, Palo Alto, CA*

Purpose: Donor derived cell-free DNA (dd cf-DNA; Allosure, CareDx) is increasingly employed for non-invasive kidney transplant monitoring. The goal of this study was 1) to examine the association between dd cf-DNA and for-cause biopsy findings and 2) describe changes in dd cf-DNA and creatinine following rejection treatment.

Methods: We included patients who 1) received a kidney transplant between May 2017 and July 2020 at our center, 2) underwent for-cause kidney transplant biopsy, 3) had ≥ 1 dd cf-DNA prior to biopsy and 4) had ≥ 2 dd cf-DNA levels measured during the entire study period. Patient demographic and clinical data were abstracted from medical records.

Results: 41 patients were stratified into 4 groups based on their most recent pre-biopsy dd cf-DNA: >1.0% (Group 1), 0.50-0.99% (Group 2), 0.21-0.49% (Group 3), and <0.21% (Group 4). Baseline characteristics are shown in table 1. The prevalence of rejection was greatest in the highest dd cf-DNA stratum (Group 1) and decreased across the 4 dd cf-DNA strata (table 2). Severe rejection (per Banff Criteria) was seen more frequently in Group 1. Only 1 patient (out of 11) in the lowest dd cf-DNA stratum (Group 4) had rejection and that was a 'borderline' T cell mediated rejection diagnosed on a background of prominent tubular injury and delayed graft function. Nearly all patients had a decrease in dd cf-DNA after treatment of rejection. Post-rejection decrease in creatinine (measured at the same time as dd cf-DNA) was less pronounced (figure 1).

Conclusions: Our study suggests that kidney transplant recipients with low dd cf-DNA (<0.21%) who undergo for-cause biopsy are unlikely to have rejection. Monitoring of dd cf-DNA may prove useful in assessing response to rejection treatment.

Table 1				
	Group 1: dd cf-DNA >1.0% (N = 12)	**Group 2: dd cf-DNA 0.50-0.99% (N=7)**	**Group 3: dd cf-DNA 0.21-0.49% (N=11)**	**Group 4: dd cf-DNA<0.21% (N=11)**

Kidney: Cardiovascular and Metabolic Complications

Abstract# 894

Risk of Statin-Related Side Effects in Kidney Transplant Recipients

S. Bae[1], J. Ahn[1], K. Lentine[2], M. A. Schnitzler[2], G. Hess[3], H. Xiao[2], D. Segev[1], M. McAdams DeMarco[1], *[1]Johns Hopkins University, Baltimore, MD, [2]Saint Louis University, Saint Louis, MO, [3]Drexel University, Philadelphia, PA*

Purpose: Statins are widely used in kidney transplant (KT) recipients for prevention of cardiovascular events. Statins' safety profile may differ in KT recipients due to their chronic comorbidities and concomitant immunosuppression. We conducted a national registry study to measure the association of statin use with the statin-related side effects in KT recipients.

Methods: We studied 101,460 adult (≥18) kidney-only recipients with Medicare Parts A, B, and D coverage in 2006-2016 using USRDS data. Use of statins was ascertained from Medicare Part D prescription drug claims and treated as a time-varying exposure. Statin-related side effects, including hemorrhagic stroke, type 2 diabetes, cataract, liver injury, and rhabdomyolysis, were ascertained from ICD-9/-10 diagnosis and procedure codes, and CPT codes in Medicare Parts A and B claims. After excluding recipients with diagnoses of the specific side effect during 30 days prior to KT, we conducted Cox regression for each side effect.

Results: The proportions of statin users were 29.6% at KT and 44.7% at 5 years post-KT. Type 2 diabetes was the most common side effect (5-year incidence=22.8%), followed by cataract (11.6%), liver injury (1.8%), hemorrhagic stroke (1.3%), and rhabdomyolysis (0.9%). Compared to non-users, statin users were at higher risk of type 2 diabetes ($aHR=_{1.78}1.87_{1.96}$), cataract ($aHR=_{1.57}1.65_{1.74}$), and rhabdomyolysis ($aHR=_{1.21}1.42_{1.68}$). The risk of hemorrhagic stroke ($aHR=_{0.70}0.81_{0.94}$) and liver injury ($aHR=_{0.90}1.02_{1.16}$) was not higher in statin users after adjustments.

Conclusions: Statins might increase the risk of type 2 diabetes, cataract, and rhabdomyolysis in KT recipients, potentially to a greater degree than they do in the general population. On the other hand, unlike the general population, KT recipients may not experience increased risk of hemorrhagic stroke or liver injury following statin use.

Table. Association of statin use with statin-related side effects in kidney transplant recipients

	Model 1 (Unadjusted)	Model 2 (M1 + recipient)	Model 3 (M2 + IS)	Model 4 (M3 + donor)
Hemorrhagic stroke	1.20 (1.05 - 1.38)	0.85 (0.74 - 0.98)	0.84 (0.73 - 0.97)	0.81 (0.70 - 0.94)
Type 2 diabetes	2.39 (2.29 - 2.50)	1.94 (1.85 - 2.03)	1.92 (1.83 - 2.01)	1.87 (1.78 - 1.96)
Cataract	2.41 (2.30 - 2.54)	1.68 (1.59 - 1.76)	1.67 (1.59 - 1.76)	1.65 (1.57 - 1.74)
Liver injury	1.16 (1.03 - 1.31)	1.05 (0.92 - 1.20)	1.05 (0.92 - 1.20)	1.02 (0.90 - 1.16)
Rhabdomyolysis	1.87 (1.60 - 2.19)	1.48 (1.25 - 1.74)	1.46 (1.24 - 1.72)	1.42 (1.21 - 1.68)

Abstract# 895

Association of Delayed Graft Function with Mortality Post-kidney Transplantation

N. Eguchi[1], H. Ichii[2], F. J. Ferrey[1], U. G. Reddy[1], D. C. Dafoe[2], H. Seo[3], K. Kalantar-Zadeh[1], E. Tantisattamo[1], *[1]Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine, Orange, CA, [2]Division of Kidney and Pancreas Transplantation, Department of Surgery, University of California Irvine, Orange, CA, [3]School of Pharmacy and Pharmaceutical Sciences, University of California Irvine, Irvine, CA*

Purpose: Given the ongoing shortage of donated organs, marginal kidneys with a higher possibility of delayed graft function(DGF) have been increasingly utilized. While DGF in kidney transplant recipients(KTR) is associated with acute kidney allograft rejection, its association with mortality is unclear.
Methods: A single-center retrospective cohort study of consecutive KTR was conducted over 2 years. DGF was defined as a dialysis requirement within 7 days post-transplant. With the study population divided into DGF and non-DGF groups, an association between DGF and all-cause mortality were examined by multiple Cox proportional hazard regression analysis. Competing risk analysis was performed to determine the association of DGF with acute rejection by using mortality as a competing risk variable.
Results: Of all 219 KTR, mean age±SD was 50±13 years and 123 patients (56%) were male. The majority were White(45%) followed by Asian(20%) and Black (2%). Up to 87 patients(40%) had diabetes and 26% had coronary artery disease. During a median follow-up of 22.2 months(0.63, 34.93), incidence rates of all-cause mortality and acute rejection were 0.002 and 0.006 person-months, respectively. Among 10 patients who died during the follow-up period, 6 patients (60%) were in the DGF group (p 0.012); whereas, only 7 out of 26 patients (27%) with acute rejection had DGF (p 0.871). Compared to the non-DGF group, the DGF group had 4.4 times greater mortality risk (HR 4.39, p 0.022, 95% CI 1.24, 15.55; Figure 1). After adjusted by age, gender, body mass index, former smoking, presence of pre-transplant diabetes, coronary artery disease, stroke, type of deceased kidney donors, the DGF group still had a significantly higher risk of death (HR 4.39, p 0.034, 95% CI 1.12, 17.22). However, DGF was not associated with acute rejection from unadjusted and adjusted competing risk analyses ($HR_{unadjusted}$ 1.05, p 0.910, 95% CI 0.44, 2.55 and sub-$HR_{adjusted}$ 1.35, p 0.515, 95% CI 0.55, 3.30).
Conclusions: While DGF was an independent risk of mortality post-transplant, it was not associated with acute rejection. Non-immunological factors may play a role in poorer survival in KTR who developed DGF. Mechanism and risk factors of mortality in patients with DGF require further studies.

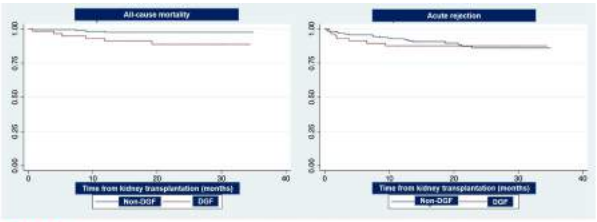

Figure 1: Kaplan-Meier curves show the statistical significance of unadjusted cumulative all-cause mortality and non-significantly unadjusted cumulative acute rejection in kidney transplant recipients with delayed graft function (DGF) compared to those without DGF.

Abstract# 896

Superior Metabolic Function of Type 2 Diabetes Mellitus Patients After Simultaneous Kidney/pancreas Transplantation Compared with Kidney Transplantation Alone

X. Y. Fu, C. Yu, H. Wang, J. Zhao, Z. Wang, C. Mo, X. Shi, G. Feng, W. Song, Z. Shen, *Tianjin First Centeral Hospital, Tianjin, China*

Purpose: To compare the renal function, metabolic profiles and survival outcomes of simultaneous pancreas kidney transplantation (SPK) and kidney transplantation alone (KTA) to end-stage renal disease (ESRD) patients with type II diabetes mellitus (T2DM).
Methods: patients with ESRD combined with T2DM who underwent SPK (n=85) or KTA (n=71) in our center were retrospectively analyzed. General demography data, perioperative parameters, postoperative blood glucose and lipid profiles, complications and survival outcomes in these two cohorts were analyzed. Repeated data were compared with mixed effect model.
Results: SPK recipients were generally younger than KTA recipients (49.01±7.98 vs. 52.14±8.34 years, p = 0.018), as well as for the age of donors (32.1±9.78 vs. 47.14±11.67 years, p <0.001)(Table1). SPK leads to superior renal function and metabolic outcomes, with higher eGFR level (p=0.393), lower fasting serum glucose level (p<0.001), lower triglyceride level (p =0.0439), and lower cholesterol level (p=0.002) (Figure 1). The rate of infection was higher in KTA group (38% vs. 22.4% , p = 0.003) (Table2). The survival outcomes were comparable between the two groups(Figrue2).
Conclusions: SPK provides better renal function and metabolic outcomes, but has higher rate of infection than KTA for ESRD-T2DM patients. The 5-year survival outcomes of recipients and grafts were comparable between the two groups.

Abstract# 897

Early Parathyroidectomy for Management of Post-transplant Hyperparathyroidism: A Case Series

A. Gokhale, J. Chancay, S. Johnson, R. P. Owen, F. Tedla, A. Bhansali, V. Sehgal, R. Shapiro, G. De Boccardo, *Recanati Miller Transplant Institute, Mount Sinai Hospital, New York, NY*

Purpose: Secondary hyperparathyroidism (HPT) gradually resolves after successful kidney transplantation (KT), and parathyroidectomy (PTX) is reserved for patients whose HPT persists longer than a year after KT. Few reports have examined the role of PTX within the first year of transplant. In this case series, we describe our experience with early PTX as treatment for post-transplant HPT that failed medical therapy.

Methods: Between August 2015 and December 2019, we identified 12 patients who underwent PTX within a year of KT. PTX was considered if HPT persisted despite treatment with the maximal tolerated dose of cinacalcet. Demographic and clinical characteristics were summarized using descriptive statistics. Estimated glomerular filtration rate (eGFR) was calculated using the Modification of Diet in Renal Disease (MDRD) formula. Intra-individual changes of relevant serum chemistry values and eGFR before and after PTX were compared with the Sign test. Statistical analysis was performed with SPSS v. 24.0; $p<0.05$ was considered significant.

Results: The median (interquartile range [IQR]) age was 54 (44-63) years; 42% were women and 83% had undergone deceased donor KT. The median daily dose of cinacalcet was 120 (60-120) mg. Pre-PTX renal biopsy showed intratubular calcium phosphate crystals in 2 patients. The median interval between KT and PTX was 169 (134 - 272) days, and the median length of stay for the PTX was 3 (3-4) days. There were no cases of permanent injury of the recurrent laryngeal nerve or chronic hypocalcemia. Before PTX, median eGFR (ml/min/1.73m2), and serum intact parathyroid hormone (iPTH, pg/mL), calcium (Ca, mg/dL), phosphorus (Phos, mg/dL), and alkaline phosphatase (ALP, U/L) were 64 (44-83), 548 (363-1032), 10.8 (9.8-11.9), 2.4 (2.2-3), and 170 (126-297), respectively. The corresponding values at 3 months post-PTX were 50 (39-68), 46 (18-154), 9.4 (9-10.5), 3 (2.6-3.2), and 75 (61-120), respectively. One year post-PTX, eGFR, and serum Ca, Phos and ALP were 49 (40-70), 9.1 (8.5-9.6), 3.2 (2.9-3.5), and 77 (50-87), respectively. Comparing intra-individual pre-PTX to post-PTX values, ALP was lower at 3 and 12 months ($p<0.01$), iPTH was lower at 3 months ($p=0.02$) and Ca at 12 months ($p<0.01$); changes in eGFR or Phos were not statistically significant at 3 or 12 months.

Conclusions: Our data suggest that early PTX is a safe and effective treatment for HPT after KT, with minimal complications. Early PTX was not associated with graft dysfunction in our study. Long term outcomes of early PTX need to be studied.

Abstract# 898

Renal Transplant Recipients with Low Skeletal Muscle Attenuation Have a Greater Risk of Developing New-onset Diabetes After Transplantation

A. Han, H. Kim, C. Chung, H. Ko, K. Choi, S. Min, S. Min, J. Ha, *Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic of*

Purpose: Decreased muscle radiation attenuation on computed tomography (CT) is indicative of fat infiltration within the muscle. Such ectopic fat accumulation has recently been recognized as a risk factor for metabolic alterations and cardiovascular disease. Here we examined the possible association between skeletal muscle attenuation and future development of new-onset diabetes after transplantation (NODAT) in renal allograft recipients.

Methods: We performed a morphometric assessment of preoperative abdominal CT scans of non-diabetic adult patients who underwent renal transplants between January 2009 and December 2014 in our transplant center. Mean skeletal muscle attenuation (SMAT), skeletal muscle index (SMI; height normalized skeletal muscle area) were assessed for non-contrast CT scans at the level of L3 vertebra. Patients with polycystic kidney disease were excluded. We examined the association between CT morphometric indices and NODAT development.

Results: Our study population included 314 adult renal allograft recipients who did not have diabetes mellitus at the time of transplant. A total of 59 (18.8%) patients developed NODAT during the mean follow-up period of 8.9 years. According to univariate cox analysis, SMAT but not SMI showed significant association with future NODAT development (HR of the lowest quartile of SMAT 2.44, 95% CI 1.45-4.09, $p=<0.001$; HR for SMI 1.02, 95%CI 0.99-105, $p=1.55$; Figure 1). Other patient and transplant factors that showed significant association with NODAT development in univariate analysis were age (HR 1.03), BMI (HR 1.16), previous diagnosis of hypertension (HR 2.67). In the multivariate model including the factors mentioned above and other known risk factors of NODAT such as HCV and tacrolimus use, SMAT remained a significant factor (HR of the lowest quartile of SMAT 1.96, 95% CI 1.04-3.69, $p=0.039$) along with age (HR 1.03, 95% CI 1.00-1.06, $p=0.023$).

Conclusions: Our study shows that decreased muscle attenuation in preoperative CT scans is associated with the development of NODAT in renal allograft recipients independent of known risk factors.

Abstract# 899

An Unexpected Case of Transthyretin Amyloid Cardiomyopathy (ATTR-CM) Overlooked Pretransplant, but Then Diagnosed Early After Kidney Transplant with a Negative Patient Outcome: A Case Report

W. Hoffman, M. Waybill, H. Yang, D. Ladie, M. Singh, *UPMC Pinnacle Transplant, Harrisburg, PA*

Purpose: ATTR-CM is underrecognized and commonly overlooked and undiagnosed. When found it is often a late diagnosis in patients with severe left ventricular hypertrophy (LVH) and diastolic heart disease. These findings are common and non-specific in patients with end-stage renal disease (ESRD) making for a challenging diagnosis.

Methods: We present a case of a 63-year-old female with a history significant for ESRD on hemodialysis, idiopathic chronic hypotension, and dysautonomia. She

had a seemingly unremarkable pre-transplant workup including for the hypotension and then underwent a deceased donor kidney transplant admitted 4 weeks later with acute onset dyspnea.

Results: On that admission, the patient required renal replacement therapy for volume overload and acute kidney injury. A kidney transplant biopsy was consistent with acute tubular necrosis but was without acute rejection. Her Kidney function improved with a baseline creatinine of 1.8-2.2. A repeat echocardiogram found severe LVH with grade 2 diastolic dysfunction, unchanged from pre-transplant but now reported to have a speckled pattern suggestive of infiltrative cardiomyopathy. Congo red staining of the kidney biopsy was negative in the renal tissue but surprisingly positive in sampled extra-renal vascular tissue suggestive of systemic amyloidosis. Her clinical picture including the history of dysautonomia, EKG findings of low QRS voltage and AV block, and increased LV wall thickness were fitting of amyloidosis. The patient underwent a TcPYP (Technetium-pyrophosphate) scan that was highly suggestive of ATTR-CM. Serum and urine protein electrophoresis and immunofixation and serum-free light chain ratios were not consistent with an immunoglobulin light chain (AL) amyloidosis. Genetic testing for mutant ATTR (ATTRm) was also negative. The patient was therefore thought to likely have wild-type ATTR (ATTRwt) and was started on Tafamidis (transthyretin selective stabilizer) therapy. The patient was planned for an endomyocardial biopsy for a definitive diagnosis. Unfortunately, before this could be completed she succumbed to sudden death likely related to cardiac arrhythmia about 7 months post-transplant.

Conclusions: This case demonstrates the need for high suspicion of cardiac amyloidosis in appropriate cases. The early and accurate diagnosis of ATTR cardiac amyloidosis is paramount given advances in noninvasive diagnostic modalities and treatment options.

Abstract# 900

Changes in Body Mass Index Before and After Kidney Transplant

M. Laub[1], S. Finder[2], P. Harikrishnan[1], M. Simon[3], I. Gani[1], M. Saeed[1], R. Kapoor[1], *[1]Augusta University Medical Center, Augusta, GA, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Brandon Wilde, Augusta, GA*

Purpose: Describe changes in body mass index (BMI) before and after kidney transplant and determine the association between BMI and graft loss or mortality.

Methods: Single center, retrospective study of adult patients undergoing kidney transplant from June 2012-June 2016. Patients were excluded if they received a repeat or multi-organ transplant, experienced death or graft loss prior to three months post-transplant, were lost to follow up, became pregnant, or underwent a weight-loss surgery. BMI at time of listing, time of transplant and post-transplant at 3 months, 1 year, 2 years, and 3 years were documented. The changes in BMI over time were analyzed using paired sample t-test. The association of BMI with graft loss and mortality were analyzed using logistic regression.

Results: A total of 202 patients met inclusion criteria; 171 patients were alive with a functioning renal graft at 3 years post-transplant. The average age at time of transplant was 54 years-old (SD 13), and the majority of subjects were African American males who received a deceased donor transplant. The average BMI at transplant listing was 29.7 kg/m^2 (SD 5.9), which significantly decreased to 29 kg/m^2 (SD 5.3) by the time of transplant (p=0.02). BMI increased post-transplant to 29.1 kg/m^2 (SD 5.3) at 3 months (p=0.69); 30.8 kg/m^2 (SD 5.6) at 1 year (p<0.01); 31.1 kg/m^2 (SD 5.6) at 2 years (p<0.01); and 31.1 kg/m^2 (SD 5.8) at 3 years (p<0.01) as compared to the time of transplant. The increase in BMI from the second year to third year after transplant was not significant. None of the baseline patient characteristics were significantly associated with extent of BMI change. The average BMI at the time of transplant for subjects who experienced graft loss (n=14) was higher than those who did not [32 kg/m^2 (SD 5.3) vs 29 kg/m^2 (SD 4.2), (p=0.02)]. The average BMI at the time of transplant for subjects who died during follow up (n=18) was similar to subjects who survived [29.6 kg/m^2 (SD 4.6) vs 29.2 kg/m^2 (SD 5.3), (p=0.76)].

Conclusions: Patients lost weight while on the wait list for kidney transplant and then gained weight post-transplant. Weight gain became significant at 1 year post-transplant and continued to increase until 2 years post-transplant, after which it plateaued. Higher BMI at transplant was associated with increased graft loss. There was no association between BMI at transplant and 3 year post-transplant mortality.

Abstract# 901

Predictors of Postoperative Atrial Fibrillation in an Urban, Obese Adult Renal Transplant Population

A. Lichvar, Z. Ress, M. Tabriz, H. Jenkins, T. Walsh, I. Tzvetanov, E. Benedetti, M. Campara, *University of Illinois at Chicago, Chicago, IL*

Purpose: Postoperative atrial fibrillation (POAF) is a common surgical complication. Renal transplant (RT) recipients possess risk factors that may lead to a higher incidence of POAF. Past evaluations did not include obese RT recipients. The purpose of this analysis is to identify factors associated with the development of POAF after RT in a diverse population.

Methods: Adult RT recipients between 1/1/2013 - 12/31/2017 at the University of Illinois Hospital were analyzed. POAF was identified by electrocardiogram. Furosemide dosing and net fluid balance were collected within the first 3 postoperative days (POD). Delayed graft function was defined as requiring dialysis within the first 7 days post-RT. The primary outcome was to describe the incidence of POAF. Demographics, pre-transplant cardiac history, and clinical course were compared between those with and without POAF. Univariate and multivariate logistic regression models were built to identify risk factors for POAF. Area under the receiver operating characteristic curve (ROC AUC) was reported in the final model.

Results: A total of 430 RT recipients were included in the analysis. The incidence of POAF was 9.3%. Demographics and cardiac history are detailed in Table 1. Those with POAF received more furosemide (p<0.001) without difference in net fluid balance (p=0.164), experienced more DGF (p<0.001), and had longer transplant admission LOS (<0.001). Clinical course outcomes are demonstrated in Table 2. Increasing age (OR 1.53, p=0.03), increasing body mass index (BMI) (OR 2.69, p<0.001), history of prior pre-RT atrial arrhythmias (OR 7.09, p=0.002), increasing IV calcium supplementation requirements (OR 1.12, p=0.005), and increasing cumulative furosemide dosing (OR 1.37, p=0.012) were associated with increased risk of POAF (Table 3). ROC AUC was 86.4% (Figure 1).

Conclusions: Judicious fluid management is required in RT recipients who are older in age, obese, and have a pre-RT history of atrial arrhythmias. Appropriate replacement of calcium and utilization of furosemide in tandem with fluid management should also be pursued. Protocols guiding fluid management in a high POAF risk population should be developed and evaluated.

Table 1. Demographic Information and Pre-Transplant Cardiac History

Variable	No POAF (n=390)	POAF (n = 40)	P-value
Age at transplant, years (SD)	48.4 (14.7)	54.9 (12.5)	0.007

Abstract# 902

The Seattle Heart Failure Model is a Predictor of Mortality After Kidney Transplant in Patients with End Stage Renal Disease and Heart Impairment

A. Perez-Gutierrez[1], P. J. Bachul[2], D. N. Danz[3], B. Juengel[2], M. Josephson[2], J. Fung[2], P. Witkowski[2], B. Chung[4], Y. Becker[2], *[1]Surgery, University of Chicago, Chicago, IL, IL, [2]Surgery, University of Chicago, Chicago, IL, [3]Economics, University of Pittsburgh, Pittsburgh, IL, [4]Cardiology, University of Chicago, Chicago, IL*

Purpose: Cardiovascular disease is the main cause of mortality after kidney transplantation. Many patients with ESRD have heart failure that is attributed to fluid overload. The Seattle heart failure model (Seattle Model) is a risk model based on clinical status, therapy and laboratory parameters. It includes the following variables: age, gender, NYHA class, ejection fraction (EF), ischemic disease, systolic BP, use of angiotensin-converting enzyme inhibitor, angiotensin receptor blocker, statin, betablocker, diuretics, allopurinol, sodium, hemoglobin, lymphocytes, uric acid, and cholesterol. It predicts survival in patients with heart failure. Our objective was to apply this model to patients with ESRD at the time of their evaluation for kidney transplant and to determine whether the model predicts mortality after transplant.

Methods: This is a retrospective study of all adult, deceased donor kidney transplants from 2014 to 2017. We used univariate and multivariate logistic regression models ($p < 0.05$).

Results: A total of 154 kidney transplant patients were reviewed. The table shows the patient characteristics and outcomes. The overall mortality was 9.7%. The one-year survival from the Seattle Model predicted all-cause mortality after transplant in patients with an EF ≤50% or the presence of ventricular hypertrophy (p=0.045, OR 0.70), this after controlling for age and gender. All input factors of the model where evaluated individually in univariate analysis and none of the factors alone was a significant predictor of mortality.

Conclusions: The Seattle Model is a useful tool to predict mortality in patients with heart failure and it does not take into account kidney function. We show for the first time that this model can be used in patients with ESRD and cardiac impairment and can help to better select patients for transplant. It can also identify those patients that need cardiac rehabilitation or treatment optimization to reduce risk of death after transplant.

Patients characteristics and outcomes	
Age	52 (20 - 79)
Male	63.6%
African American	72.7%
BMI (median)	27.5 (18.2 - 46.1)
HTN	35.7%
DM2	26%

Patients characteristics and outcomes (cont)	
Years on dialysis	6.7 (0.7 - 17.5)
Smoking	44.2%
Ischemic disease	15.6%
Delayed graft function	45.6%
Rejection	14.9%
Death	9.7%

Abstract# 903

Effect of Insulin versus Oral Agents on Early Glycemic Control Following Kidney Transplant

A. Petrosan, A. Santeusanio, R. Khaim, V. Delaney, *Mount Sinai Hospital, New York, NY*

Purpose: Insulin therapy is commonly prescribed to treat hyperglycemia early post-kidney transplant (KTx) due to its widespread availability and ease of titration. Alternatively, there is limited evidence analyzing the comparative effectiveness of oral therapies on glycemic outcomes following KTx.

Methods: This was a single-center, retrospective cohort study of adult KTx recipients with new or worsening hyperglycemia requiring treatment between 01/2014-05/2020. Patients were excluded if they had received a prior or combined organ transplant, had a history of type 1 diabetes or HIV, were converted to belatacept, or were on intensive insulin prior to transplant. Patients discharged on oral medications were matched in a 1:1 ratio to patients receiving intensive insulin based on pre-transplant diabetes regimen, baseline hemoglobin A1c (HbA1c), duration of diabetes, and steroid maintenance. The primary endpoint was the number of hyperglycemia-related readmissions within 6 months of KTx. Key secondary endpoints included HbA1c at 6 months post-transplant, serum glucose levels and documented hypoglycemia within 1 month of KTx, and treated urinary or bloodstream infections.

Results: 30 patients prescribed intensive insulin were matched to 30 patients receiving oral therapies based on clinical parameters. Four patients in each group were discharged on chronic steroid therapy, while others received dual tacrolimus and mycophenolate. Baseline characteristics were similar between groups, with the exception of more Caucasians in the insulin group (53.5% vs 26.7%; p=0.04). There were no differences between groups in the incidence of the primary endpoint (3.3% vs 6.7%; p=0.55) or all-cause readmissions within 30 days (26.7% vs 26.7%; p=1.00); however, 9 patients in the oral group required the use of emergency sliding scale insulin and 7 (23.3%) subsequently were converted to standing insulin. HbA1c at 6 months was similar between groups (7.0 vs 7.3; p=0.49), and no differences were observed in serum glucose levels during follow-up (179.9 vs 179.8; p=0.99). There were also no significant differences in the incidence of laboratory reported hypoglycemia or weight change at 6 months. More insulin patients were treated for urinary or bloodstream infections, however this did not reach statistical significance (23.3% vs 13.3%; p=0.32).

Conclusions: This study suggests that the early use of oral antiglycemics post-KTx in selected patients results in similar outcomes relative to insulin therapy. Rigorous follow-up of blood glucose levels is still required, as up to 25% of patients may require conversion to intensive insulin within the first month. Practitioners should consider concomitant comorbidities, lifestyle preferences, and patient goals of care when selecting patients for oral therapies.

Abstract# 904

Kidney Transplantation in Patients with Severe Pulmonary Hypertension: Not an Absolute Contraindication?

B. Prajapati[1], D. Gumber[2], I. Moinuddin[1], C. Bhati[1], G. Gupta[1], D. Grinnan[3], D. Kumar[1], *[1]Nephrology, Virginia Commonwealth University, Richmond, VA, [2]Cardiology, Virginia Commonwealth University, Richmond, VA, [3]Pulmonology, Virginia Commonwealth University, Richmond, VA*

Purpose: Severe pulmonary arterial hypertension (PAH) as defined by a pulmonary artery systolic pressure (PASP) >50mmHg is associated with high peri-operative mortality and thus is usually considered a contraindication to kidney transplantation. In this preliminary study, we describe the pre-kidney transplant management and post-transplant outcomes in patients with severe PAH using a multidisciplinary care team approach.

Methods: Between November 2013 and August 2020 we identified all patients with severe PAH on initial pre-transplant workup who underwent ultrafiltration (UF) and/or medical therapy for PAH prior to kidney transplant. After transplant we evaluated their peri-operative course, renal function, graft and patient survival.

Results: Fourteen patients (mean age=56±12years, AA race: 8/14; 57%) were diagnosed with severe PAH on pre transplant screening echocardiogram. These findings were confirmed by right heart catheterization (RHC) (mean PASP 63.4±15mmHg). These patients were also noted to have an elevated pulmonary capillary wedge pressure (mean PCWP 23.4±6.4mmHg) and right atrial pressure (mean RA 12.1±3.6mmHg). Based upon a diagnosis of mixed PAH with a post-capillary component, patients were subjected to aggressive mechanical ultrafiltration (UF; mean 4.6±1.6 sessions) with an average weight loss of 5.5±2.1kg at the end of the UF sessions. Twelve (out of 14; 86%) patients underwent repeat RHC and were noted to have a marked decline in PASP from an average of 65±16 to 33±12 mmHg, in PCWP from 23.5±7 to 7.4±3.4 mmHg and in RA pressure from 12.1±3.6 to 3.17±2.0 mmHg. Four (29%) patients were on vasodilator (phosphodiesterase type 5; PDE5 inhibitor therapy) prior to UF and remained on those after UF and through transplant. Majority of these patients received a deceased donor kidney transplant (12/14; 86%). Two (14%) of the patients had a planned one-day ICU stay after surgery, six (42%) had a 30-day readmission and nine (64%) of the patients had delayed graft function. The mean eGFR at 3, 6, 9 and 12 months was 70.69±27, 70.23±27, 74.92±30 and 73.09±32 ml/min/1.73m^2. At a mean follow-up of 28±21 months post-transplant both graft and patient survival are 100%.

Conclusions: In this small single center study, we report that severe PAH should not be considered an absolute contra-indication to kidney transplantation. A better elucidation of the etiology of PAH with a RHC should be considered. Post-capillary PAH can be a significant and common contributor to elevations in PASP and mean PAP especially in the dialysis population. Using a multidisciplinary approach, PAH could be improved with optimal volume removal and PDE5 inhibitor therapy leading to a complication free peri-operative period and a successful post-transplant outcome.

Abstract# 905

Screening, Management and Acceptance of Patients with Aortoiliac Vascular Disease for Kidney Transplantation: An International Survey Among Transplant Surgeons

E. Rijkse[1], H. J. Kimenai[1], F. J. Dor[2], J. N. IJzermans[3], R. C. Minnee[1], *[1]HPB/Transplant Surgery, Erasmus Medical Center, Rotterdam, Netherlands, [2]Imperial College Transplant Centre, Hammersmith Hospital, London, United Kingdom, [3]HPB/Transplant surgery, Erasmus Medical Center, Rotterdam, Netherlands*

Purpose: Aortoiliac vascular disease (AVD) is frequently observed during the work-up for kidney transplantation, but recommendations on its screening and management are lacking. We aimed to assess differences in screening, management and acceptance of these patients for transplantation by performing an international survey among transplant surgeons. Secondly, we aimed to identify center- and surgeon-related factors associated with either declining or accepting kidney transplant candidates with AVD.

Methods: A survey was sent to transplant surgeons worldwide. The survey contained general questions and 2 patient-based cases with Trans-Atlantic Inter-Society Consensus (TASC) D and B AVD supported with videos of their CT-scans.

Results: 191 (20.3%) potential participants responded; 171 were currently involved in kidney transplantation; 145 (84.8%) completed the survey. Screening for AVD was mostly (37.2%) restricted to high-risk patients. Pre-transplantation vascular interventions were infrequently performed (71.7% mentioned <10 per year). If needed, 67.5% would perform an open vascular intervention before transplantation and 32.5% simultaneously. The likelihood to decline a patient for transplantation was higher in the TASC D case compared to TASC B (26.9% and 9.7%). Respondents from centers with expertise in pretransplant vascular interventions were more likely to accept both patients with TASC D and B for transplantation.

Conclusions: Heterogeneity exists concerning management of transplant candidates with AVD. A multidisciplinary meeting where technical feasibility and comorbidity are discussed could aid in providing equal access to transplantation. Referral to centers with experience in pretransplant vascular procedures may increase the chance of acceptance of patients with AVD for transplantation.

Abstract# 906

Renal Transplant is Safe in Septuagenarians

P. Serrano Rodriguez, J. Vonderau, K. Szempruch, C. S. Desai, *Abdominal Transplant Surgery, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Purpose: With increasing life expectancy, there has been increase in transplant rates amongst elderly recipients who often have more comorbidities than younger recipient. The aim of the study was to evaluate the outcomes of septuagenarian kidney transplant (KT) recipients.

Methods: Single-center, retrospective cohort study was conducted to evaluate outcomes of recipients more than 70 years old who underwent KT with respect to 1-3-5 year graft and patient survival and peri-operative outcomes like length of stay and delay graft function. For assessment of the results which can be meaningful, we compared it to recipients between age 65 and 69 who underwent KT. We divided the groups in cohort 1 65-69 years old, and cohort 2 70-79 years old. EHR charts were reviewed for hospital stay, need for ICU management, delay graft function and primary non function. We adjusted for patient comorbidities common in this patient population, which include, hypertension, diabetes mellitus, coronary artery disease, cerebral vascular disease, peripheral vascular disease, and chronic obstructive pulmonary disease. T-test was used for comparisons of parametric continuous variables and Mann-Whitney U test was utilized for nonparametric continuous variables.

Results: From April 2014 to July 2019 55 kidney transplants were performed in cohort 1and 28 in cohort 2. Cohort 1 54% were male, 42% White, 47% Black, 11% other; 27% received living donor (LD), 23% donation after cardiac death (DCD) and 49% brain death donor (BDD). In cohort 2 40% were male, 53% were white, 43% were black and 4% other. 32% received LD, 10% DCD, 58% BDD. One-, three- and five-year graft and patient survival were 94%, 91% and 91%in cohort 1 and 100% in cohort 2 (p=NS). Mean length of stay (LOS) was 8 days for both cohorts with a median of 6 days. Readmission in first 30 days was 18.2% and 33.3% respectively, delay graft function (DGF) was 18.2% and 22.2% respectively.

Conclusions: We did not find significant differences between the 65-69 year old and the 70-79 year old after adjusting for comorbidities. We found that more women and white patients were in the cohort 2. Kidney transplant is a safe and adequate procedure in septuagenarian recipients.

Abstract# 907

Early Hypertransaminasemia in Kidney Transplant Recipient: Influence of Donor Type and Clinical Significance

E. Solà-Porta, M. Redondo-Pachón, S. Núñez-Delgado, C. Arias-Cabrales, M. Mir, A. Buxeda, C. Burballa, M. Crespo, J. Pascual, M. Pérez-Sáez, *Nephrology, Hospital del Mar, Barcelona, Spain*

Purpose: The increase in transaminases after kidney transplant (KT) is frequent. Although the cause is unknown, it has been associated with factors such as immunosuppression, infections and cross-talk between liver and kidney in ischemia-reperfusion situations. However, the influence of the type of donor has not been evaluated. We analyze the incidence, relevance and meaning of post-KT hypertransaminasemia.

Methods: Retrospective study (2004-2018) to analyze the increase in serum AST/ALT during the first 3 months after KT in 119 consecutive KT recipients of deceased donors either brain death (DBD), controlled after cardiac death (cDCD) or uncontrolled after cardiac death (uDCD). All donors received induction with thymoglobulin and maintenance with tacrolimus and mycophenolate.

Results: Comparing the donor groups, in the uDCD group (n=39) donors and recipients were younger, there were more first transplants and prolonged delayed graft function, although creatinine was similar at 3 months. There were no differences in liver disease history, cold ischemia time, or post-KT hypotension. There were no differences in thymoglobulin induction dose, and uDCD recipients presented lower levels of tacrolimus at one week post-KT. At 72 hours post-KT, 69.2/82.1% of uDCD recipients presented elevation of AST/ALT over the normal values (vs 22/29.3% DBD and 21.1/21.1% cDCD, p<0.001) and 30.8/56.4% presented an elevation of AST/ALT twice over the normal values (vs 6.8/12.1% DBD and 5/5% cDCD, p=0.024/<0.001). This elevation was resolved early, one moth after KT AST/ALT values in all groups were below normal limits (Figure). In the multivariate analysis, donor type was associated with hypertransaminasemia at 72 hours post-KT and, in the uDCD group, hypertransaminasemia was not associated with a prolonged delayed graft function (creatinine decrease> 15 days post-KT).

Conclusions: Post-transplant hypertransaminasemia is frequent and is associated with the type of kidney donor. This finding is temporary and is not related to a prolonged delayed graft function.

Abstract# 908

Sodium Zirconium Cyclosilicate Use in Kidney Transplant Recipients

K. J. Swanson, F. Aziz, S. Parajuli, M. Mohamed, D. A. Mandelbrot, A. Djamali, N. Garg, *University of Wisconsin-Madison, Madison, WI*

Purpose: Hyperkalemia is a common problem experienced by kidney transplant recipients (KTR)s. New strategies to treat hyperkalemia are now available. KTRs often require medications that raise serum potassium (K). Sodium zirconium cyclosilicate (ZS-9) lowers serum K levels via exchanging sodium and hydrogen for potassium in the gastrointestinal tract. Its safety and efficacy in KTRs is unknown.
Methods: This was a single-center retrospective analysis of KTRs with hyperkalemia (serum K >5.1mEq) treated with sodium zirconium cyclosilicate from 12/2019 - 10/2020. Treatment was determined by electronic medical record review of the medication administration record and/or documented use. Primary outcomes were need for renal replacement therapy and change in serum K at ~ 48 hours (mmol/L). Secondary outcomes included use of potassium raising medications, mean change in tacrolimus level (ng/dL), significant hypokalemia (serum K <3.0mmol/L), major gastrointestinal adverse outcomes (bleed, perforation, ischemic colitis, post-operative ileus) and hypersensitivity reactions.
Results: 27 KTRs with hyperkalemia were treated with ZS-9 from 12/2019 - 10/2020. Mean age at transplant was 52 years. Median time to use since transplant was 0.75 years. Most patients were white (17, 63%) men (23, 85%). Diabetes mellitus (11, 41%) and glomerulonephritis (10, 37%) were the leading causes of end stage kidney disease. 5 (19%) patients were living donor recipients. Basiliximab (18, 67%) was the primary induction agent used. Most patients (22, 81%) were on standard triple maintenance immunosuppression. Mean baseline serum creatinine was 3.71 ± 2.84 mg/dL. 16 (59%) of the patients were inpatient. 6 (23%) had delayed graft function. 5 (19%) had slow graft function. Mean total ZS-9 used was 30 gm; mean doses utilized was 3. 9 patients were treated with ZS-9 within 30 days of transplant. The remaining 18 received ZS-9 thereafter. Primary outcomes wise, 6 patients (22%) required hemodialysis. 3 (50%) underwent hemodialysis for hyperkalemia. The mean decrease in K at ~48 hours was 0.8 ± 0.5 mmol/L. In steady state patients (n = 5), tacrolimus levels remained stable with the mean change of 1.3 ± 0.7 ng/mL. Patients were also able to remain on potassium raising medications e.g. prophylactic (n=4) and treatment (n =1 for *Pneumocystis* pneumonia, 1 for *Nocardiosis*) dosed trimethoprim-sulfamethoxazole, angiotensin-converting enzyme inhibitors/angiotensin receptor blockers/mineralocorticoid receptor antagonists (n=4), treatment dosed heparin (n=2), and azoles (n=2). Safety wise, no major adverse outcomes were observed. Edema is a concern but could not be assessed precisely due to multiple, dynamic factors driving fluid status in this population.
Conclusions: Sodium zirconium cyclosilicate appears to be an effective, safe medication in KTRs. More studies are needed to characterize its use in the kidney transplant population.

Abstract# 909

Dietary Intake of Calories and Protein in the Acute Phase Following Kidney Transplant: Opportunities for Improvement

L. Teigen[1], G. Onyeaghala[1], Y. Doronin[2], B. Guo[1], B. Wu[1], J. Abrahante[1], D. Schladt[1], W. Guan[1], C. Staley[1], M. Al-Kofahi[1], S. Riad[1], A. Matas[1], R. Remmel[1], W. Oetting[1], C. Dorr[1], P. Jacobson[1], A. Israni[1], *[1]University of Minnesota, Minneapolis, MN, [2]Hennepin Healthcare Research Institute, Minneapolis, MN*

Purpose: Nutritional therapy post kidney transplant includes both an acute (1-1.5 months post-transplant) and a chronic phase. To date, most of the available literature has focused on the metabolic derangements (e.g. obesity, diabetes) associated with the chronic phase. Adequate nutrition during the acute phase, however, is essential to support an increased metabolic demand following surgery and to begin correction of altered body composition (e.g. sarcopenia) associated with end stage renal disease, which is important for long-term metabolic health. Currently, recommendations support calorie intakes of up to 35 kcal/kg/d and protein intakes of up to 1.5 g/kg/d, but little is known about dietary intake during the acute post transplantation phase.
Methods: In the Microbiome and Immunosuppression in Kidney Transplantation (MISSION) study, we collected baseline 48 hours food recalls up to 20 days after kidney transplantation for 7 participants, using the Nutrition Data System for Research (NDSR). Descriptive tables and figures were generated using SAS version 9.4.
Results: Demographic characteristics, calorie, and protein intake of the study cohort are presented in **Table 1**. Calorie and protein intake collected during the 3 weeks post-transplant correlated positively (r=0.84). Calorie intake ranged from 20 kcal/kg/d to 34 kcal/kg/d and protein intake ranged from 0.7 g/kg/d to 1.5 g/kg/d. Only 1/7 (14%) kidney transplant recipients achieved a calorie intake of ~35 kcal/kg/d. Similarly, only 1/7 (14%) patients achieved a protein intake of 1.5 g/kg/d. Notably, 4/7 (57%) patients had protein intakes less than 1.0 g/kg/d.
Conclusions: These preliminary findings suggest an opportunity to optimize nutritional intake in the acute period following kidney transplantation. Given the negative impact of end stage renal disease on body composition, it is important to ensure adequate nutritional intake begins in the acute post-transplantation phase to help support both recovery from surgery and prevention of long-term metabolic complications.

Table 1: Demographics and Dietary Intake

Variable	
Body Mass Index (BMI; kg/m^2); Median (Min, Max)	27.3 (23.3, 27.8)
Sex (Female:Male)	3:4
Donor Type (Living:Deceased)	4:3
Calorie Intake (kcal/kg/d); Median (Min, Max)	22.4 (19.8, 34.3)
Protein Intake (g/kg/d); Median (Min, Max)	0.8 (0.7, 1.5)

Abstract# 910

Clinical Effect of Post-transplant Av-fistula Ligation on Hemodynamic Status and Kidney Allograft Function

S. Valavoor, J. Powelson, A. Sharfuddin, O. Adebiyi, *Nephrology, Indiana University, Indianapolis, IN*

Purpose: Ligation of AVF post kidney transplant often done mostly for esthetic reasons, however, they are occasionally indicated in the presence severe steal syndrome, severe heart failure or pulmonary hypertension. Several observational studies have shown conflicting outcome with respect to the clinical implication of post kidney transplant AV-Fistula ligation on hemodynamics and allograft function. A few observational studies have shown worse outcome with increased risk for accelerated kidney allograft decline with no remarkable effect on blood pressure profile post AVF ligation. We conducted an observational study in our academic center to see the effects of AVF ligation on Hypertension and kidney function parameters at one-year post procedure.

Methods: This was an observational case series with retrospective chart review of patients who underwent AVF ligation between January 1 2015 and September 30 2019 with a minimal of one year follow up. Patient with baseline history of kidney allograft rejection, donor specific antibodies (DSA) or with rising serum creatinine leading to the AVF ligation were excluded from the study. Blood pressure profile including the number of anti-hypertensive medications in use, serum creatinine and Urine protein creatine ratio were compared at 12 months before and after procedure.

Results: Sixty-four patients were included in the study. There was no clinically significant difference in Mean Serum Creatinine and Mean Urine Protein-Creatinine ratio at 12 months before and 12 months after AVF ligation. However, there was a modest increase in the mean MAP from 93 mmhg at 12 months before AVF ligation to 99 mmhg at 12 months after procedure (Delta positive change of 6 mmhg).

Conclusions: Post-kidney transplant AV fistula Ligation appears to have no significant effect on kidney allograft function one-year post procedure though it may be associated with higher blood pressure.

Abstract# 911

Risk Factors for Low Bone Density and Vertebral Fracture in Kidney Transplant Recipients: A Cross-sectional Cohort Study

A. Velioglu[1], B. Kaya[1], B. Aykent[1], B. Ozkan[2], M. S. Karapinar[1], H. Arikan[1], E. Asicioglu[1], O. Bugdayci[3], D. Gogas Yavuz[4], S. Tuglular[1], *[1]Nephrology, Marmara University School of Medicine, Istanbul, Turkey, [2]Marmara University School of Medicine, Istanbul, Turkey, [3]Radiology, Marmara University School of Medicine, Istanbul, Turkey, [4]Endocrinology, Marmara University School of Medicine, Istanbul, Turkey*

Purpose: Kidney transplantation (KT) recipients are at increased risk of low bone density (LMD) and fractures. In this retrospective study, we investigated bone mineral density (BMD), vertebral fractures, calculated risk for major osteoporotic fractures (MOF) and hip fractures in the KT recipients.

Methods: Patients completed at least one year after KT were included in the analysis. Demographic, clinical, and laboratory data were recorded. Measurements of BMD were performed by dual-energy X-ray absorptiometry. Vertebral fractures were assessed using semi-quantitative criteria with conventional radiography. The ten-year risk for MOF and hip fracture were calculated using the FRAX@ tool with BMD.

Results: One hundred fifty-three KT recipients were included in the study. The population included 77 women. The mean age at evaluation was 46,5±11,9years. Seventy-eight (50.9%) patients had normal femoral neck BMD while osteoporosis and osteopenia at the femoral neck were present in 12 (7.8%) and 63 (41.1%) of the patients, respectively. Age at evaluation was the risk factor for LMD (OR 1.057; 95% CI 1.024-1.091; p=0.001). In female KT recipients, LMD was principally affected by menopausal status whereas in males, mammalian target of rapamycin (mTOR) inhibitor use and lower BMI levels were the risk factors. The prevalent vertebral fracture was found in 43.4% of patients. In multivariate analysis, only steroid use (OR 0.121; 95% CI 0.015-0.988; p=0.049) was found to be associated with prevalent fracture. Among all KT recipients, 1.9% had a high MOF probability (≥20% risk of fracture), and 23.5% had high hip fracture probability (≥3% risk of hip fracture).

Conclusions: Exploring the prevalence of LBD and vertebral fracture and the risk factors would help clinicians to modify long-term follow-up strategies. Furthermore, the high hip fracture risk probability in our cohort suggested that there is a need for longitudinal studies to confirm the validity of the FRAX tool in the transplant population.

Abstract# 912

The Association of Pre-Kidney Transplant C-Peptide Level with Post Transplant Outcomes

A. J. Vinson, K. Tennankore, *Nova Scotia Health Authority Division of Nephrology, Departm, Halifax, NS, Canada*

Purpose: Insulin is produced by pancreatic beta-cells by cleavage of a prohormone precursor into equal parts insulin and C-peptide. C-peptide has been shown to have renoprotective properties including decreasing microalbuminuria, reduced hyperfiltration injury, and regression of diabetic histologic changes on kidney biopsy when administered to type 1 diabetics. In animal models, C-peptide also protects against ischemia-reperfusion injury. How pre-transplant C-peptide levels relate to outcomes after kidney transplantation has not been previously explored.

Methods: We identified a cohort of non-diabetic adult patients who underwent kidney transplant in Halifax, Nova Scotia between January 1, 2016-December 31, 2018 who had fasting C-peptide levels measured immediately prior to transplant. The association of pre-transplant C-peptide level dichotomized around the median and i. delayed graft function (DGF), ii. proteinuria and iii. median estimated glomerular filtration rate (eGFR) at one year was determined and statistical differences were identified using Fischer's exact or Wilcoxon rank-sum methods where appropriate. C-peptide level was also examined as a continuous variable and categorized into quartiles. We used multivariable linear regression to determine the association of pre-transplant C-peptide level with eGFR at one year post-transplant.

Results: Mean and median pre-transplant C-peptide levels were 3458 and 3118 pmol/L, respectively. As such, in an initial analysis, pre-transplant C-peptide level was dichotomized at 3000 pmol/L. The incidence of DGF was higher 8/31 (25.8%) amongst those with low C-peptide levels, compared with 6/33 (18.2%) for those with levels ≥ 3000. The eGFR was lower at 1 year in those with a C-peptide < 3000 compared with ≥ 3000 (49.8 ± 4.1 versus 60.0 ± 4.2, p-value 0.0877). When C-peptide was instead categorized based on quartile, eGFR again increased steadily from the lowest to highest quartile, Table 1, likewise, the percentage with proteinuria at 1 year also increased. When C-peptide was treated as a continuous variable, the association between C-peptide and eGFR at one year post transplant was significant (coefficient = 0.0043, 95% CI 0.00038-0.0081, p-value 0.032).

Conclusions: A higher pre-transplant C-peptide level is associated with a lower risk of DGF, and a higher eGFR and lower proportion with proteinuria at one year after kidney transplant.

Pre-Transplant C-Peptide Level (pmol/L)	eGFR at 1 year (mL/min/1.73m²) (Q1, Q3)	DGF* (%)	Proteinuria > Trace at 1 year (%)
≤1940	46.4 (27.4, 71.4)	12 (25.5)	7 (43.8)
1940-3118	48.8 (32.0, 62.2)		5 (29.4)
3118-4616	55.0 (48.8, 86.5)		4 (26.7)
>4616	57.3 (39.7, 67.7)	2 (12.5)	4 (25.0)

*DGF dichotomized due to a low number of events.

Kidney

Kidney Immunosuppression: Desensitization

Abstract# 913

Deceased Donor Transplantation Across Positive Flow Crossmatch - A Single Center Experience

M. Campara, A. Lichvar, J. Benken, S. Patel, C. Muran, D. Pierce, I. Tang, P. Di Cocco, J. Almario Alvarez, M. Spaggiari, E. Benedetti, I. Tzvetanov, *University of Illinois at Chicago, Chicago, IL*

Purpose: Transplantation across a positive flow crossmatch (+FXM) has been established as a lifesaving measure in the living donor setting. Time required for desensitization limits utility in deceased donor transplants (DDTx). We report outcomes of +FXM DDTx recipients using conventional and modified desensitization applied in the postoperative setting.

Methods: Adult +FXM DDTx recipients from 7/2018 to 6/2020 were analyzed. Crossmatch was done by local HLA lab or organ procurement organization. No patients received waitlist desensitization. Standard of care was Plasmapheresis(PP)/Thymoglobulin 2.5mg/kg (IBW) on POD0,1,3,5,7,9 and IVIG 150mg/kg (IBW) on POD2,4,6,8. A subset of patients received PP/bortezomib 1.3mg/m² on POD1,4,8,11 and Thymoglobulin 1.5mg/kg (IBW) on POD0-4. Discharge IS consisted of TAC, MPA, and prednisone.

Results: Twenty six patients received +FXM DDTx. All had negative standard XM. Majority (92.3%) received isolated kidney, were female (57.7%) and black (46.1%). **Table 1** details demographic and IS. T cell +FXM was present in 73.1% cases, and B cell +FXM in 80.8% cases. Patient outcomes are provided in Table2. Three patients

(11.5%) experienced delayed graft function. Four patients (16%) received rejection treatment (1/BPAR requiring IVIG/PP/Thymoglobulin; and 3/with steroids). At 6 months, mean eGFR was 57+/- 34.9 ml/min. Patients with longer follow up showed stable eGFR out to 24 months (Figure 1). Majority (69.2%) remained on TAC/MPA/Pred at last follow up. Seven patients (27%) required IS manipulation (4 for infection [57.2%] and 2 for leucopenia [28.6%]). Two patients died, both due to infection related complications; neither experienced rejection. Serial DSA screening was performed in 92.3% cases, with 54% showing negative Class I and 75% showing negative Class II DSA at last follow up, Table 3. Majority of patients had a decline in both Class I (72.7%) and Class II (54.5%) DSA strength index at last follow up.
Conclusions: Decreased donor transplantation across +FXM may be an option for a select group of patients but requires close monitoring and swift IS modification to ensure optimal outcomes.

Table 1: Baseline Demographics

Variable	N = 26
Age at transplant, y (SD)	52.5 (10.2)

Abstract# 914

Iguratimod Reduce Panel Reactive Antibody in High Mismatched Renal Transplant Recipients: A Retrospective Propensity Score-Matched Study

D. Feng, Z. Wang, Z. Han, J. Tao, X. Ju, R. Tan, M. Gu, *The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Purpose: To evaluate the clinical efficacy and safety of iguratimod (IGU) for reducing panel reactive antibody (PRA) in high mismatched renal transplant recipients.
Methods: Eligible recipients found positive PRA with or without IGU administered were enrolled. Propensity score matching (PSM) analysis was conducted to eliminate the difference between the IGU group and the No IGU group. After adjustment, MFI changes of PRA before and after drug treatment between the two groups were assessed. Adverse reactions or side effects were also reviewed.
Results: 54 recipients were included eventually after 1:1 matching analysis. 340 and 144 PRA sites were detected in the IGU group and the No IGU group, respectively. The proportion of PRA sites with decreased MFI was obviously higher in the IGU group than in the No IGU group. After IGU taken for 9 months, significantly MFI decrease was seen in anti-HLA class I, anti-HLA class II, anti-HLA class I and class II, anti-HLA A, anti-HLA B, anti-HLA Cw, anti-HLA DQ and anti-HLA DR antibody sites (P <0.05), except of anti-HLA DP antibody sites (P >0.05). Decrease of PRA in the IGU group was greater than in the No IGU group in anti-HLA class I, anti-HLA class II, anti-HLA class I and class II, anti-HLA A, anti-HLA DR antibody sites (P <0.05), except in anti-HLA Cw, anti-HLA DP and anti-HLA DQ antibody sites (P >0.05). Adverse reactions or side effects was identical between the two groups (P >0.05).
Conclusions: IGU can effectively reduce PRA in high mismatched renal transplant recipients and can be applied safely without serious adverse effects.

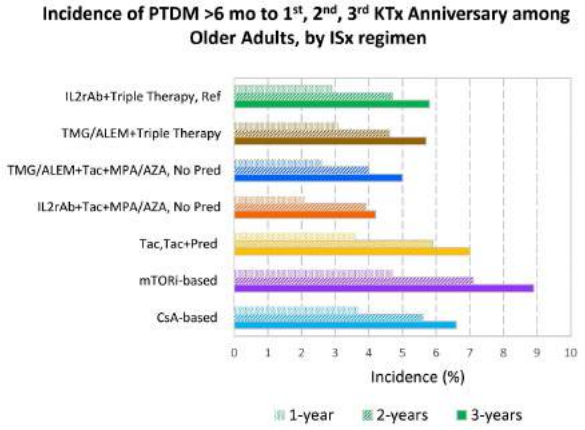
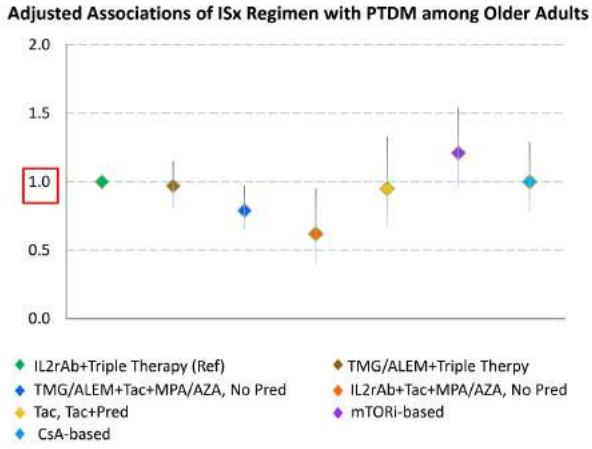
Abstract# 916

Immunosuppression Regimen and Risk of Posttransplant Diabetes Among Older Kidney Transplant Recipients

K. Lentine[1], J. Ahn[2], M. McAdams Demarco[2], H. Xiao[1], S. Bunnapradist[3], D. Segev[2], D. Axelrod[1], S. Bae[2], V. Dharnidharka[4], Y. Caliskan[1], S. Chang[4], G. Hess[5], J. Snyder[6], M. Schnitzler[1], *[1]Saint Louis Univ, Saint Louis, MO, [2]Johns Hopkins, Baltimore, MD, [3]Univ of California, Los Angeles, Los Angeles, CA, [4]Washington Univ, Saint Louis, MO, [5]Drexel Univ, Philadelphia, PA, [6]SRTR, Minneapolis, MN*

Purpose: Posttransplant diabetes mellitus (PTDM) is a common complication after kidney transplantation (KTx), which may be exacerbated by immunosuppressive therapy (ISx). Older adults tend to have lower acute rejection risk due to immunosenescence but increased risk of non-immune complications, including PTDM. We examined associations of ISx and PTDM among adults 55 years and older using national US transplant registry data.
Methods: We examined a linkage of Scientific Registry of Transplant Recipients (SRTR) and Medicare claims (2005-2016). Induction agent use was defined by registry reporting. Early maintenance ISx regimen was defined using Medicare pharmacy claims for ISx agents submitted within the first 6 months after transplant, and patients were classified into 7 regimens (**Figure**). Diabetes diagnosis was ascertained from Medicare claims. We modeled associations ($_{95\%LCL}$aHR$_{95\%UCL}$) of ISx regimen with PTDM >6 months to 3 years posttransplant, compared with a reference regimen of IL2-receptor antibody (IL2rAb) induction + triple maintenance (Tac + MPA mycophenolic acid: MMF or mycophenolate sodium)/azathioprine (AZA) + prednisone (Pred)) using Cox regression. Models were adjusted for potentially confounding differences in distributions of demographic and clinical factors using inverse probability of treatment weighting (IPTW).
Results: Among 31,740 recipients aged ≥55 without pretransplant diabetes, 61% were men, 54% were white, 24.5% Black, and 15.2% Hispanic. Overall, 5.9% developed PTDM by 3 years. The unadjusted incidence of PTDM was lower among those who received TMG/ALEM+Tac+MPA/AZA,No Pred (5.0%) and IL2rAb+Tac+MPA/AZA,No Pred (4.1%) compared with the reference regimen (5.7%) but trended higher in those who received mTORi-based (8.9%) or CsA-based regimens (6.6%). After adjusting for potential confounding using IPTW, TMG/ALEM+Tac+MPA/AZA,No Pred was associated with 21% lower risk of PTMD (aHR, $_{0.65}0.79_{0.97}$) and IL2rAb+Tac+MPA/AZA,No Pred was associated with 38% lower risk (aHR, $_{0.40}0.62_{0.95}$).





Conclusions: Steroid-free ISx is associated with lower risk of PTDM among older adult KTx recipients. Risk of non-immune complications should be considered along with rejection risk in tailoring immunosuppression choice in older adults.

Abstract# 917

Desensitization with Plasmapheresis and IV Immunoglobulin is Safe and Effective in Pra Positive Kidney Transplant Recipient Candidates in Covid-19 Pandemic Period

B. Sayin[1], A. Akdur[2], E. Karakaya[2], U. Musabak[3], T. Colak[1], M. Haberal[2], *[1]Department of Nephrology, Baskent University, Ankara, Turkey, [2]Division of Transplantation, Department of General Surgery, Baskent University, Ankara, Turkey, [3]Department of Immunology, Baskent University, Ankara, Turkey*

Purpose: High panel reactive antibody (PRA) levels may limit living-donor kidney transplantation (LDKT) according to increased risk of antibody mediated rejection. Desensitization may provide better graft survival rates in high-risk KT recipient candidates. We aimed to share our desensitization experience in LDKT recipients in COVID-19 pandemic period (March 1 to September 2, 2020).

Methods: At Baskent University Transplantation Center, we performed desensitization protocol of plasmapheresis (5 sessions) and intravenous immunoglobulin(IVIG of 2g/kg) in three KT recipients who had high PRA levels.

Results: Three sensitized KT recipients candidates had a mean age of 25.3 years and mean fluorescence intensity (MFI) level of 13862. All the patients were receiving their second transplant and had PRA class II positivity with percentages of 77%, 56% and 66% respectively. After desensitization, all the recipients became cross-match negative and LDKT was performed successfully for all. No acute rejection episodes were detected either in the early period or in the three months period after LDKT. Patients had a mean creatinin level of 0,83 mg/dL in the 7th day and 0,88mg/dL in the 3rd month after LDKT without significant proteinuria. No complication according to COVID-19 and no sign of infection was obtained.

Conclusions: In conclusion, desensitization with 5 sessions of plasmapheresis and 2g/kg of IV immunoglobulin provide safe and effective desensitization in PRA positive LDKT recipients even in the COVID-19 pandemic period.

Abstract# 918

Safety and Tolerability of Tacrolimus Extended-Release (astagraf Xl) in Hla Sensitized Kidney Transplant Recipients: A Single Center Experience

A. A. Vo, N. Ammerman, E. Huang, A. Peng, R. Najjar, S. Sethi, K. Lim, M. Gillespie, S. C. Jordan, *Cedars Sinai Medical Ctr, Los Angeles, CA*

Purpose: Pill burden is a limitation in kidney transplant. Tacrolimus extended-release (Astagraf XL) is a once daily formulation approved for kidney transplantation. Increased compliance could reduce or possibly modify allosensitization in HS patients and improve outcomes. Here we report on a pilot, open label, single-arm, non-controlled design study to determine safety and tolerability of Astagraf XL in HS renal transplant patients.

Methods: All HS patients received desensitization with IVIG 2g/kg (>70kg max 140g) and rituximab 375mg/m^2 ± PLEX, induction with alemtuzumab and maintained with Astagraf XL, MMF, and pred taper post-tx. Monitoring parameters included BPAR, graft failure or death and AEs/SAEs @12M.

Results: Twenty HS patients were enrolled from 9/2017-11/2019. Table 1 showed overall outcomes. Overall, 80% of patients had previous transplant, 75% had DSA at transplant, and 55% had positive FCMX with 2 patients developed dnDSA @12M post-tx. Rejections occurred in 6 patients (30%) {active/cABMR (2); chronic active CMR/ABMR (2); early TG (1) & CMR (1)} . Four patients had BK viremia. eGFR @12M was: 71±24 ml/min/1.73m^2. Mean tacrolimus dose @Day 365 was: 5.4±1.9mg with mean level of 8.2±3.0 (goal 5-8ng/ml). Patient and graft survival @12M were 100%. AEs included: mouth ulcer (1), perinephric fluid collection (1), BKAN grade 2 with stable Scr (1). SAEs included: bacteremia (1); DKA (1); incisional abscess & AKI (1).

Conclusions: Astagraf XL in HS patients was safe and effective in this high risk, HS population with similar rejection rates (30%) and dnDSA generation (22%) compared to our previous experience with tacrolimus twice daily.

Kidney

Kidney Immunosuppression: Induction Therapy

Abstract# 919

A Question with Multiple Answers: Do Renal Transplant Recipients Require Steroid Maintenance Following Thymoglobulin Induction?

A. Aala, H. Patel, F. Cardarelli, *Beth Israel Deaconess Medical Center, Boston, MA*

Purpose: Anti-thymocyte globulin (ATG) has been used with good results in renal transplantation as induction therapy, followed by triple immunosuppression with calcineurin inhibitors, antimetabolites, and steroids. In 2004, steroids avoidance regimens started to be used by transplant centers, and since the year 2007, about 30% of kidney transplant patients in the USA have been discharged without steroid maintenance therapy. In this study, we evaluated outcomes of kidney transplant recipients who received ATG and were maintained on steroids and compared them to patients who did not receive steroid maintenance therapy after transplant using UNOS/OPTN database.

Methods: We conducted a retrospective cohort analysis of the UNOS database. We identified all kidney transplant patients who received ATG as induction therapy between January 2007 & December 2018. We divided the cohort based on whether they received steroids as part of maintenance immunosuppression or not, and compared transplant and patient outcomes. Baseline donor and recipient characteristics were compared between groups using Student t-test or Kruskal Wallis test for continuous variables and Chi-2 test for categorical variables. Kaplan Meier curve was used to measure graft survival time.

Results: A total of 89,044 patients were identified who received their first renal transplant between the year 2007 and 2018. Of them, 29,825 [33.5%] recipients received ATG and did not receive steroid maintenance therapy on discharge. Patients without steroid maintenance had significantly higher acute rejection rate compared to patients who received steroid maintenance therapy, (7.3% vs 6.4% p < .001). Similarly, graft failure rate at 1st year was significantly higher among the recipients who received steroid free maintenance immunosuppressive therapy (2.5% vs 2.2%, p=0.009). There was no significant difference in graft survival time, patient survival time and graft failure rate at 3rd (p=0.64) and 5th (p=0.086) year post transplant between the groups.

Conclusions: Compared to patients who receive ATG induction with steroid maintenance therapy, recipients who receive ATG without steroids have higher acute rejection rate and allograft failure rate at 1 year after transplant. However, there is no significant difference in graft and patient survival rate at 3rd and 5th year post transplant.

Abstract# 920

A Comparative Analysis of Kidney Allograft Outcomes in Steroid Use versus Steroid Discontinuation After Basiliximab Induction: Unos Data Base Study

F. Cardarelli, H. Patel, A. Aala, *Nephrology, BIDMC, Boston, MA*

Purpose: Basiliximab is a monoclonal antibody produced by recombinant DNA technology used by many transplant centers in the U.S. as induction immunosuppression. When Basiliximab is used, most of the patients are kept on maintenance steroids vs early steroid withdrawal in some centers. With this study, we seek to evaluate rejection, graft and patient survival rates among recipients who received Basiliximab and were maintained on steroids compared to early steroid withdrawal.

Methods: We conducted a retrospective cohort analysis of the UNOS database. We identified all kidney transplant patients who received Basiliximab as induction therapy between January 2007 & December 2018. We divided the cohort based on whether they received steroids as part of maintenance immunosuppression or not, and compared risk factors of graft loss among them. Baseline donor and recipient characteristics were compared between groups using Student t-test or Kruskal Wallis test for continuous variables and Chi-2 test for categorical variables. Kaplan Meier curve and cox-regression analysis was used to measure graft and patient survival time.

Results: A total of 33,914 patients who received Basiliximab induction were identified. Of them, 29,152 [85.9%] recipient received steroids as maintenance immunosuppression and 4,762 [14.0%] underwent early steroid withdrawal. Recipients kept on maintenance steroids had significantly higher acute rejection rate at one year post transplant compared to those who did not receive steroids [9.1% vs 8.0%, p=0.01]. However, kidney allograft failure rate at 5 years was significantly lower among patients who were on steroid maintenance compared to steroid-free [6.3% vs 7.3%, p=0.009]. Of the recipients who suffered graft failure, death censored graft survival time was significantly higher among the recipients who received steroids (p=0.009). Allograft survival advantage remained statistically significant after adjustment for age>70 years, delayed graft function, KDPI>85% and female donor. Finally, patient's death rate at 5 year post transplant was significantly lower among the recipients who received steroids compared to the other group (9.1% vs 11.6%, p<0.001).

Conclusions: In spite of higher rejection rates within the first year of transplant, kidney allograft survival rate was significantly higher among recipients who received Basiliximab induction and were maintained on steroids compared to recipients who underwent early steroid withdrawal. Patient survival was also significantly higher among patients maintained on steroids compared to early steroid withdrawal.

	Multivariate HR (95% CI)	p-value
Age>=70	1.45 [1.25 – 1.70]	<0.001
Delayed graft function	1.78 [1.61 – 1.96]	<0.001
KDPI>85%	1.23 [1.06 – 1.43]	0.005
Donor gender(Female)	1.09 [1.001 – 1.19]	0.048

Abstract# 921

Cost Savings Initiative with Idea Body Weight Dosing of Rabbit Anti-thymocyte Globulin (rATG) Induction in an Older Kidney Transplant Population: A Single Center Analysis

C. LaFratte[1], S. Witek[1], D. Sawinski[2], J. Trofe-Clark[2], C. Sammons[2], B. Hardek[1], R. Samudralwar[1], A. Forte[1], S. Lyle[1], J. Rashid[1], G. Malat[2], *[1]Pharmacy, Hospital of Univ of Pennsylvania, Philadelphia, PA, [2]Penn Transplant Institute, Hospital of Univ of Pennsylvania, Philadelphia, PA*

Purpose: Optimal dosing schemes for rATG induction are not well defined for older kidney transplant recipients (KTRs), who are at greater risk for adverse events from

over-immunosuppression. The goals of this study are to assess potential cost-savings with ideal body weight (IBW) vs actual body weight (ABW) rATG induction dosing schemes while maintaining efficacy in older KTRs.

Methods: This retrospective single-center cohort study included 1st and 2nd KTRs age ≥ 60 years transplanted 4/2016-12/2019. Multi-organ KTRs and KTRs with HIV, HCV, or < 30 days follow-up were excluded. Standard immunosuppression included rATG, tacrolimus, mycophenolate, and prednisone taper. KTRs were grouped by total rATG given for induction: the ABW group received > 110% of an IBW-based dose, and the IBW group received ≤ 110% of an IBW-based dose. Costs were calculated by the average wholesale price (AWP) of rATG. The ABW group served as a control for safety and efficacy outcomes within 1-yr post-op. Patients were censored upon graft failure, death, or any safety outcome.

Results: An interim analysis was performed on 52 KTRs (IBW group n=15; ABW group n=37). KTRs in both groups were similar at baseline (Table 1). IBW-based dosing of rATG resulted in a median cost savings of $4,240/patient (IQR $3,150-$6,300) and a total savings potential of $171,166 within the ABW group. Safety and efficacy data were similar between groups (Table 2).

Table 1. Older KTR Demographics at Transplant

Baseline Characteristic	IBW (n=15)	ABW (n=37)	p-value
Age, median (IQR)	64 (61-66)	65 (62-68)	0.58
Sex, n (%)			
Male	10 (66.7)	19 (51.4)	0.35
Race/Ethnicity, n (%)			
Black	4 (26.7)	15 (40.5)	0.53
Non-Black	11 (73.3)	22 (59.5)	
Dialysis Pre-Transplant, n (%)	13 (86.7)	25 (67.6)	1
Kidney Donor Profile Index, median (IQR)	70 (43-79)	49 (40-70)	0.25
Deceased Donor, n (%)	11 (73.3)	26 (70.3)	1
Prior Kidney Transplant, n (%)	0 (0)	2 (5.4)	1
White Blood Cells ($x10^3$ cells/mm^3), median (IQR)	7.4 (4.8-10.1)	6.2 (4.4-8.4)	0.42
Platelets ($x10^3$ cells/mm^3), median (IQR)	161 (150.5-179.5)	160 (131-181)	0.81
Calculated Panel Reactive Antibodies, median (IQR)	0 (0-0)	0 (0-0)	0.82

Table 2. Safety and Efficacy Outcomes in Older KTRs

Outcome (within one year of transplant)	IBW (n=15) n (%)	ABW (n=37) n (%)	p-value
Leukopenia White blood cells < $3x10^3$ cells/mm^3	6 (40)	14 (37.8)	1
Thrombocytopenia Platelets < $75x10^3$ cells/mm^3	6 (40)	18 (48.6)	0.76
Opportunistic Infections	3 (20)	7 (18.9)	1
BK Virus	1 (6.7)	3 (8.1)	1
Cytomegalovirus	1 (6.7)	3 (8.1)	1
Epstein-Barr Virus	1 (6.7)	1 (2.7)	0.50
Hospital Re-presentation	11 (73.3)	25 (67.6)	0.75
Biopsy-proven Acute Rejection	1 (6.7)	0 (0)	0.29

There were no graft failures and 1 KTR death, which was in the ABW group.

Conclusions: An interim analysis showed an opportunity for cost savings with IBW-based rATG induction dosing. There were no differences in safety or efficacy between groups. Data collection/analysis are ongoing.

Abstract# 922

The Impact of Fixed-Dose Alemtuzumab in Renal Transplant Recipients According to Weight

S. Mandala[1], N. Khodieva[2], A. Bigness[1], S. Mohamed[2], H. Mohammed[1], K. Robichaux[2], A. Brueckner[3], R. Baliga[4], J. Buggs[5], A. Kumar[1], L. Bowman[3], *[1]Morsani College of Medicine, University of South Florida, Tampa, FL, [2]Honors College, University of South Florida, Tampa, FL, [3]Transplant Pharmacy, Tampa General Hospital, Tampa, FL, [4]Nephrology, Florida Kidney Physicians, Tampa, FL, [5]Transplant Surgery, Tampa General Hospital, Tampa, FL*

Purpose: Alemtuzumab, a potent anti-CD52 monoclonal antibody is used for induction immunosuppression post-renal transplantation as a fixed 30mg dose regardless of the patient's weight. The aim of this study was to evaluate the safety and efficacy of 30mg alemtuzumab induction immunosuppression in kidney transplant recipients (KTR) based on patient weight. We hypothesized that lower weight patients would have a higher incidence of leukopenia and infection compared to higher body weight patients.

Methods: We conducted a retrospective cohort study of adult (≥18 years) KTR between January 2015 and December 2017 at a single center. Patients were divided into study groups based on their weight (≤60 kg, 61-74 kg, ≥75 kg). All patients received a 30mg fixed dose of alemtuzumab for induction immunosuppression.

Results: A total of 445 patients were included in our analysis: ≤60kg group (n=59), 61-74kg group (n=113), ≥75kg group (n=273). There was no difference in the incidence of acute rejection, graft loss, or death at 12 months between groups (figure 1). There was a trend towards higher rates of readmission due to leukopenia at 12 months in the ≤60kg group, but no difference in readmission secondary to infection (figure 2). While there was no difference in BK viremia or nephropathy, there was a trend toward a higher incidence of CMV viremia in the ≤60kg group (32.2% vs. 19.5% and 19% in the other two cohorts; p=0.07).

Conclusions: While there was a trend toward a higher incidence of hospital readmission due to leukopenia and numerically higher incidence of CMV viremia in KTR ≤60kg that received alemtuzumab 30mg for induction immunosuppression, these findings should be further evaluated in a larger cohort of low body weight adult KTRs. In addition, the safety of fixed-dose alemtuzumab 30mg should be evaluated in other weight ranges to better determine the safety and efficacy of a fixed-dose in all patients regardless of weight.

Abstract# 923

Rabbit Anti-thymocyte Globulin Induction Dosing Strategies in a High-risk Kidney Transplant Population

C. Nguyen, R. Yau, C. Tunwar, *Pharmacy, CHI Baylor St. Luke's Medical Center, Houston, TX*

Purpose: The objective of this retrospective observational study is to compare the safety and efficacy of two dosing strategies, rabbit anti-thymocyte globulin (rATG) at a total cumulative dose of 4.5 mg/kg versus rATG at a total cumulative dose of 6 mg/kg, in high-risk renal transplant patients (re-transplant, panel reactive antibodies > 20%, presence of donor specific antibodies, African Americans < 60 years old, or other ethnicities < 50 years old).

Methods: A retrospective chart review was conducted in patients who received a renal transplant at CHI Baylor St. Luke's Medical Center (BSLMC) from January 2019 to September 2020. The following three-month outcomes were analyzed between the two rATG dosing groups: patient survival, graft survival, and incidence of rejection. Secondary outcomes included incidence of thrombocytopenia, leukopenia, infusion related reaction, delayed graft function, and infection.

Results: A total of 117 patients were included in this study. With regard to patient and graft survival at three months, 100% of the 4.5 mg/kg group (n=46) and 98.6% of the 6 mg/kg group (n=71) survived (*P*=1). Graft rejection at three months occurred in 6.5% of patients in the 4.5 mg/kg group and 5.6% in the 6 mg/kg group (*P* =1). Incidence of secondary outcomes in the 4.5 mg/kg and 6 mg/kg group, respectively, were the following: thrombocytopenia (41.3%, 50.7%, *P*=0.348), leukopenia (41.3%, 45.0%, *P*=0.707), infusion related reaction (0%, 2.8%, *P*=0.519), delayed graft function (21.7%, 22.5%, *P*=1), and infection (60.9%, 56.3%, *P*=0.703).

Conclusions: rATG at a total cumulative dose of 4.5 mg/kg is just as effective as 6 mg/kg. There was no significant difference in patient survival, graft survival, or incidence of rejection within three months from transplant. There was also no difference in any of the secondary and safety outcomes analyzed. The lower total dose may result in cost savings.

Abstract# 924

Preemptive Second Kidney Transplant Outcomes by Induction Type in the United States

S. Riad[1], G. Larrieux[2], S. Jackson[3], R. Kandaswamy[2], *[1]Medicine, University of Minnesota, Minneapolis, MN, [2]Surgery, University of Minnesota, Minneapolis, MN, [3]Complex Care Analytics, M-Health Fairview, Minneapolis, MN*

Purpose: Failed kidney allograft is the fourth leading indication for kidney transplantation. A significant portion of second kidney transplant recipients undergo preemptive transplantation while on maintenance immunosuppression. We examined the association between the type of induction used and long-term graft and recipient survival.

Methods: Using the SRTR, we identified all preemptive second kidney transplant recipients. We excluded those with missing or unusual induction regimens, recipients with maintenance other than tacrolimus and Mycophenolate +/- steroids and those with crossmatch positive results. We grouped recipients by induction type into four groups: Anti-thymocyte globulin group (n=1335), Alemtuzumab group (n=332), IL-2 Receptor Antagonist group (n=477) and No-induction group (n=165). We generated Kaplan-Meier curves of recipient survival **(RS)** and death-censored graft survival **(DCGS)** with follow up censored at ten-year post-transplant. We used Cox proportional hazards models to examine the effect of induction along with other factors on the outcomes of interest. To account for center specific effect, we included center as a random effect. We adjusted for recipient age, gender, race, diabetes, PVD, ESRD etiology, donor type and gender, HLA-MM, steroid maintenance, time between transplants, payor type and transplant year. The **(RS)** model was stratified by donor gender and HLA-Mismatch, whereas the **(DCGS)** model was stratified by donor type due to proportional hazards violations.

Results: Glomerulonephritis was the leading cause of ESRD among the groups accounting for over 40% of the recipients. Rates of DGF, rejection, hospitalization, and PTLD at one year were not statistically different. Mean creatinine was slightly higher in the no-induction group. In the Kaplan-Meier analyses, neither **(RS)** (log-rank p=0.729) nor **(DCGS)** (log-rank p=0.077) (Figure 1) differed by induction type. In the fully adjusted models, induction type was not a predictor of recipient or graft survival. Live-donor kidney was a favorable predictor of **(RS)** [aHR 0.66, 95% C.I. (0.50, 0.86), p=0.002]. Publicly insured recipients had worse recipient and allograft survival outcomes.

Conclusions: In this large cohort of crossmatch negative second pre-emptive kidney transplant recipients who were discharged on tacrolimus and mycophenolate maintenance, induction type was not associated with improved rejection rates, recipient or graft survival. Live-donor kidneys improved recipient survival.

Abstract# 925

Outcomes of Second Kidney Transplant After Return to Dialysis by Induction Type in the United States

S. Riad[1], T. Shaker[1], S. Jackson[2], R. Kandaswamy[3], *[1]Medicine, University of Minnesota, Minneapolis, MN, [2]Complex Care Analytics, M-Health Fairview, Minneapolis, MN, [3]Surgery, University of Minnesota, Minneapolis, MN*

Purpose: A failed kidney allograft is the 4th leading indication for kidney transplantation. We examined the association of induction use in 2nd kidney transplant recipients after returning to dialysis and the long-term recipient survival **(RS)** and death censored graft survival **(DCGS)**.

Methods: Using the SRTR database, we identified all 2nd kidney recipients who returned to dialysis before re-transplantation. We excluded those with missing or unusual induction regimens, recipients with maintenance other than Tac and MMF +/- steroids and those with crossmatch positive results. We grouped recipients by induction type into 4 groups: Anti-thymocyte globulin (n=9233), Alemtuzumab (n=1846), IL-2RA (n=1969) and No-induction (n=811). We generated Kaplan-Meier curves of **(RS)** and **(DCGS)** with follow up censored at 10-year post-transplant. We used Cox proportional hazard **(PH)** models to examine the association of induction with these outcomes. We included center as a random effect. We adjusted for recipient age, gender, race, DM, PVD, ESRD etiology, donor type and gender, HLA-MM, steroid maintenance, time between transplants, payor type and transplant year. The **(RS)** model was stratified by transplant year; the **(DCGS)** model was stratified by time between transplants, time on dialysis, recipient age and donor age due to (**PH)** violations.

Results: Rejection and PTLD rates at 1-year were not statistically different. DGF and re-hospitalization rates were lower, but mean creatinine was higher in the no induction group compared to the other groups. In the univariate analyses, **(RS)** did not differ by induction type (log-rank p=0.50). However, **(DCGS)** was the lowest in the no-induction group (log-rank p <0.001) (Figure 1). After adjustment, induction type was not a predictor of **(RS)** or **(DCGS)**. Steroid maintenance was associated with better **(DCGS)** [aHR 0.86, 95% C.I. (0.76, 0.98), p=0.02]. Live-donor kidney was a favorable predictor of **(RS)** [aHR 0.75, 95% C.I. (0.67, 0.85), p<0.001] and **(DCGS)** [aHR 0.75, 95% C.I. (0.67, 0.85), p<0.001]. Publicly insured recipients had worse **(RS)** and **(DCGS)**.

Conclusions: In this large cohort of crossmatch negative second kidney transplant recipients, who were on dialysis prior to re-transplantation and discharged on Tac and MMF maintenance, recipients of no-induction had worse graft survival in the univariate analysis. In the fully adjusted models, induction type was not a predictor of **(RS)** or **(DCGS)**. Live-donor kidneys improved recipient and graft survival.

Abstract# 926

Outcomes in Standard vs. Extended Use of Thymoglobulin as Induction Therapy in Kidney Transplant Recipients

N. M. Sifontis[1], A. Coleman[1], D. Tang[1], K. Lau[2], S. Karhadkar[2], A. DiCarlo[2], A. Diamond[2], *[1]Temple University School of Pharmacy, Philadelphia, PA, [2]Temple University Health System, Philadelphia, PA*

Purpose: Thymoglobulin induction along with modern maintenance immunosuppression has been found to have a significant reduction in acute rejection in kidney transplantation. The recommended duration to complete thymoglobulin is within 4-7 days after kidney transplant (KT). Due to its toxicity profile and cost, some centers have moved towards an expanded duration of thymoglobulin in the outpatient setting, but the efficacy of this strategy is unknown. The purpose of this research was to evaluate outcomes in KT recipients who received standard vs. extended duration of thymoglobulin.

Methods: All KT recipients who received thymoglobulin induction between January 1st, 2017 to December 31st 2019 were included. Patients were divided into two groups (standard therapy (ST): completion of thymoglobulin induction within 7 days of KT) and (extended therapy (ET): completion of thymoglobulin induction after 7 days after KT). The primary outcomes were the incidence of delayed graft function (DGF), biopsy confirmed acute rejection at 6 months and graft and patient survival at 12 months.

Results:

Table 1. Baseline characteristics			
	ST group (n=47)	ET group (n=57)	p-value
Recipient age at transplant (years), mean ±SD	53.98 ± 11.34	50.81 ± 13.68	0.21
Male gender, n(%)	30 (64)	37 (65)	0.91
KDPI, median [IQR]	37.5 [17-49]	30.5 [24.3-49.5]	0.61
%cPRA, median [IQR]	0 [0-10]	10 [0-53]	0.14
Total thymoglobulin dose (mg/kg), mean ±SD	4.44±0.91	5±0.87	0.001
Duration of thymoglobulin (days), mean ±SD	6±1	9±2	<0.001
Delayed graft function, n(%)	12 (25)	23 (40)	0.11

The majority of patients were middle-aged, male, and African American (43% in the ST group vs. 60% in the ET group; p< 0.01). The majority received maintenance immunosuppression with tacrolimus, mycophenolate with or without prednisone. The incidence of acute rejection was 15% vs 12% in the ST group vs. ET group, respectively; p=0.15. There was no graft loss at 12 months. There were two non-kidney related deaths (1 death in each group) at 12 months.

Conclusions: This data suggests that extended use of thymoglobulin for induction therapy is common at our institution. This strategy did not appear to negatively impact short term kidney transplant outcomes such as acute rejection. KT recipients who experienced DGF were more likely to receive ET most likely to delay the start of calcineurin inhibitors. Larger studies are warranted to fully evaluate the impact of this strategy in kidney transplantation.

Abstract# 927

Sirolimus (srl) versus Everolimus (evr) versus Mycophenolate (mpa) in Kidney Transplant Recipients Receiving Anti-thymocyte Globulin Induction (r-atg), Tacrolimus (tac), and Prednisone

H. Tedesco Silva Junior, C. Felipe, L. Viana, M. Cristelli, N. Tenorio, V. Lima, V. Azevedo, K. Ficher, J. Rezende, R. Foresto, M. Nakamura, Y. Dreige, J. Taddeo, C. Zito, J. Medina, *Hospital do Rim, Universidade Federal de São Paulo, São Paulo, Brazil*

Purpose: The aim of this study is to compare the efficacy and safety of SRL versus EVR versus MPA in kidney transplant recipients.

Methods: This is a single center, prospective and randomized trial in kidney transplant recipients receiving a single 3 mg/kg dose of r-ATG induction therapy, tacrolimus and faster prednisone taper (Clinicaltrials.govNCT03468478). Randomized patients receive SRL (3mg QD adjusted to maintain concentrations between 4 to 8 ng/mL), EVR (3mg BID adjusted to maintain concentrations between 4 to 8ng/mL), or MPA (720 mg BID). All patients received preemptive treatment for CMV infection. The primary endpoint was the incidence of CMV infection at 12 months.

Results: This analysis includes data from 267 kidney transplants recipients receiving SRL(n=87), EVR(n=91), or MPA(n=89). Key efficacy and safety outcomes are shown in Table. The incidence of CMV infection was lower in SRL and EVR groups compared to MPA group but there were no differences in the proportion of patients with CMV specific cellular immunity based on the Quantiferon (QTF) test or with BKV viremia. There was no difference in the incidence of biopsy proven acute rejection (BPAR), incidence of de novo DSA, graft loss or death. At 12 months, there was no difference in renal function or in Banff scores of protocol biopsies.

Conclusions: These data confirms and expands previous observations regarding the comparable efficacy of mTOR inhibitors and lower incidence of CMV infection.

Conclusions: .

Parameters	SRL, N=87	EVR, N=91	MPA, N=89
CMV infection/disease, n(%)	7(8)	6(6,6)	39(43,8)

Abstract# LB 78

Alemtuzumab vs Antithymocyte Globulin Induction in Hepatitis C Viremic Donors to Hepatis C Negative Kidney Transplant Recipients

K. Walter, L. Mincemoyer, J. Giang, J. Suero, N. Shah, K. Szempruch, *University of North Carolina Medical Center, Chapel Hill, NC*

Purpose: The optimal induction agent for kidney transplantation of hepatitis C virus nucleic acid test positive donors to negative recipients (HCV NAT D+/R-) is unknown. Achievement of HCV cure with directed acting antivirals (DAA) post-transplant has been reported in HCV NAT D+/R- kidney transplant recipients who received antithymocyte globulin (ATG) induction, yet theoretical concerns for over immunosuppression with alemtuzumab (ALEM) exist. We sought to compare ALEM vs ATG induction on HCV clearance and transplant outcomes in a cohort of HCV NAT D+/R- kidney transplant recipients.

Methods: A single center, retrospective analysis comparing ALEM vs ATG induction in HCV NAT D+/R- adult kidney transplant recipients from July 2018 to December 2020 was conducted. Multi-organ transplant recipients were excluded. Maintenance therapy included tacrolimus, mycophenolate, and a 3-day steroid taper. DAA were determined by HCV genotype and payer preference. The primary outcome was achievement of sustained virologic response 12 weeks (SVR12) after therapy completion.

Results: 20 recipients were included (7 ALEM, 13 ATG); 15 reached SVR12 at the time of data analysis. There were no differences in baseline characteristics between groups (Table 1). The majority of recipients were treated with glecaprevir/pibrentasvir for 12 weeks, initiated at a mean of 44 days posttransplant (range 22-88 days). There was no difference in achievement of SVR12 between groups (100% ALEM vs 100% ATG). Biopsy proven acute rejection within 6 months occurred in one recipient in each group. The recipient in the ALEM group who developed antibody mediated rejection was highly sensitized prior to transplant. One recipient in the ATG group experienced an adverse event from DAA therapy leading to its discontinuation.

Conclusions: In HCV NAT D+/R- kidney transplant recipients initiated on a DAA posttransplant, the use of ALEM induction did not impact HCV clearance or transplantation outcomes compared to ATG induction in this limited series.

Kidney

Kidney Immunosuppression: Novel Regimens and Drug Minimization

Abstract# 928

Effect of Early Steroid Withdrawal on Posttransplant Diabetes Mellitus Among Kidney Transplant Recipients Differs by Recipient Age

J. Ahn[1], S. Bae[1], M. Schnitzler[2], G. Hess[3], K. Lentine[2], D. Segev[1], M. McAdams-DeMarco[1], *[1]Johns Hopkins University, Baltimore, MD, [2]Saint Louis University, St. Louis, MO, [3]Drexel University, Philadelphia, PA*

Purpose: Posttransplant diabetes mellitus (PTDM) is a major complication after kidney transplantation (KT) often attributable to immunosuppression. The risk of PTDM may increase with more potent steroid maintenance and older recipient age.

Methods: Using USRDS data, we studied 12,488 adults (age≥18) first-time KT recipients (2010-2015) without diabetes at the time of KT. We compared the risk of PTDM among recipients underwent early steroid withdrawal (ESW) versus those continued steroid maintenance (CSM) using Cox regression with inverse probability weighting to adjust for confounding. We also tested whether the risk of PTDM resulting from CSM differed by recipient age (18-29, 30-54 and 55+ years).

Results: Of 12,488, 28.3% recipients received ESW. The incidence rate for PTDM was 13 per 100 person-years (11 per 100 person-years in ESW; 14 per 100 person-years in CSM). Overall, ESW was associated with lower risk of PTDM compared with CSM (aHR=$_{0.72}0.79_{0.86}$) but the risk differed by recipient age. ESW was associated with lower risk of PTDM among old (aged 55+) recipients (aHR=$_{0.62}0.71_{0.81}$), but not among young (aged 18-29) recipients (aHR=$_{0.81}1.18_{1.72}$, interaction p=0.01).

Table. Effect of early steroid withdrawal (versus continued steroid maintenance) on posttransplant diabetes mellitus among kidney transplant recipients by recipient age (18-29, 30-54, and 55+)

	N	aHR	P for interaction
Overall	12,488	$_{0.72}0.79_{0.86}$	-
Recipient age			
18-29	1,123	$_{0.81}1.18_{1.72}$	-
30-54	6,567	$_{0.73}0.83_{0.95}$	0.09
55+	4,798	$_{0.62}0.71_{0.81}$	0.01

Conclusions: Early immunosuppression strategy should be tailored among old recipients to balance the risks and benefits.

Abstract# 929

Evaluation of Rituximab-abbs in Renal Transplant: A Case Series

A. Dao[1], B. Jimenez[2], A. Reyad[1], J. Guiteau[1], M. Madhrira[3], N. Umezurike[1], S. Patel[1], S. Allam[3], *[1]Transplant, Medical City Fort Worth, Fort Worth, TX, [2]College of Pharmacy, University of North Texas, Fort Worth, TX, [3]Tarrant Nephrology Associates, Premier Physicians Group Health, Fort Worth, TX*

Purpose: Biosimilars are FDA-approved alternatives to cost-prohibitive biologics, with no clinically meaningful differences in safety, purity, and potency. Rituximab-abbs, a biosimilar to rituximab, has labeled indications for several oncologic and autoimmune conditions. There is currently no published literature on the use of rituximab-abbs in the renal transplant population. In this report, we describe the safety and efficacy in renal transplants who received rituximab-abbs at our center.

Methods: This is a retrospective chart review of renal transplants who received rituximab-abbs between June to December 2020. Indications, safety, and clinical outcomes were reviewed. Per institutional standard of care, renal transplants with donor-specific antibodies (DSA) greater than 2000 MFI at time of transplant receive rituximab-abbs 375 mg/m^2 intravenously once as part of induction therapy. For antibody medicated rejection (AMR), one dose is given at the end of the treatment course with plasmapheresis, bortezomib, corticosteroids, and enhanced maintenance immunosuppression.

Results: Five patients received rituximab-abbs between the time period: 1 for baseline DSA, 4 for AMR. Patient characteristics and clinical outcomes are summarized in Table 1. All patients received appropriate pre-medications. No infusion-mediated reactions were reported. At a median follow-up of 72 days, no incidence of leukopenia (WBC < 3x10^9/L), documented infections, and other serious adverse effects were reported. All patients achieved peak DSA MFI reduction and/or resolution at time of last follow-up. In contrast to rituximab, utilization of rituximab-abbs in these 5 patients resulted in a $13,275.78 cost-saving.

Conclusions: Rituximab-abbs is a safe, well-tolerated, and cost-effective alternative to rituximab for the treatment of DSA in renal transplant patients. Further studies are necessary to determine efficacy of rituximab-abbs in DSA reduction in renal transplants.

Abstract# 930

Evaluation of Conversion to Extended-Release Tacrolimus in Abdominal Organ and Thoracic Transplant Recipients

A. Diamond[1], N. Agarwal[2], A. Younas[2], N. Sifontis[2], J. Au[1], C. Ruggia-Check[1], *[1]Pharmacy, Temple University Hospital, Philadelphia, PA, [2]Pharmacy, Temple University School of Pharmacy, Philadelphia, PA*

Purpose: An established approach for conversion from immediate-release tacrolimus (IR TAC) to extended-release tacrolimus (LCPT) in kidney transplantation exists, but is lacking in other organ populations. Due to recent shortages of IR TAC, an increase in use of LCPT is seen in all organ populations. To broaden our understanding of the

optimal approach in converting from IR TAC to LCPT, the purpose of this study is to identify differences in conversion ratios amongst all organ populations compared to current conversion recommendations.

Methods: One hundred twenty-four transplant recipients were included (43 kidney, 8 kidney/pancreas, 6 liver, 17 heart, and 50 lung). The primary outcome was the conversion ratio from IR TAC to LCPT required to achieve therapeutic TAC trough levels. Secondary outcomes included pre-conversion IR TAC dosage, LCPT dosage at time of therapeutic TAC trough level, and serum creatinine (SCr) at time of therapeutic TAC trough level.

Results: Mean age at transplantation was 59.9 ± 11.8 years. A lower mean age and a higher percentage of African American and Hispanic patients were noted in the abdominal organ transplant (AOT) population compared to the thoracic transplant population. Ethnicity was self-reported. At conversion, 72% of patients were at a therapeutic TAC trough level. The mean conversion ratio at time of conversion from IR TAC to LCPT was 1:0.91 for all organ populations. At the time of achieving therapeutic TAC trough levels, the mean conversion ratio required to reach therapeutic TAC trough level was 1:0.91 with lower median conversion ratios required in thoracic transplant recipients (1:0.81 for heart and 1:0.79 for lung) compared to AOT recipients (1:1 for kidney, 1:1 for kidney/pancreas, and 1:0.95 for liver). A longer than desirable time to reach therapeutic level was noted which may be due to varying frequency in checking TAC trough levels. No notable changes in mean SCr at conversion to time to achieve therapeutic level were observed (1.46 mg/dL vs. 1.57 mg/dL).

Table 1

	All Patients (N= 124)	Kidney (N= 43)	Lung (N= 50)	Heart (N= 17)	Kidney/ Pancreas (N= 8)	Liver (N= 6)
Age (years), mean ± SD	59.9 ± 11.8	57.1 ± 11.5	65.3 ± 8.8	61.4 ± 10.7	45.3 ± 13.2	54.8 ± 12.4
Ethnicity, n (%) White; Black; Hispanic	62 (50); 46 (37); 14 (11)	11 (26); 22 (51); 8 (18)	39 (78); 9 (18); 2 (0.04)	9 (53); 7 (41); 1 (0.06)	0 (0); 5 (63); 3 (38)	3 (50); 3 (50); 0 (0)
Mean pre-conversion IR TAC daily dose (mg/day), mean ± SD	6.73 ± 4.27	6.72 ± 3.82	6.64 ± 4.39	5.32 ± 2.88	8.12 ± 6.83	9.75 ± 4.86
Median initial conversion ratio (IR TAC : LCPT), mg : mg	1 : 0.9	1 : 1	1 : 0.8	1 : 0.8	1 : 1	1 : 1
Median conversion ratio at time of achieving therapeutic TAC trough level (IR TAC : LCPT), mg : mg	1 : 0.89	1 : 1	1 : 0.79	1 : 0.81	1 : 1	1 : 0.95
Mean LCPT dose, (mg/day), mean ± SD At conversion; Post-conversion at therapeutic TAC trough level	6.09 ± 4.23; 5.95 ± 4.06	6.61 ± 4.45; 6.49 ± 4.04	5.5 ± 3.51; 5.29 ± 3.54	4.5 ± 2.51; 4.34 ± 2.38	8.25 ± 7.17; 8.5 ± 7.11	9 ± 5.37; 8.83 ± 7.5
Time to achieve therapeutic level (days), mean	49.9	68.7	24.3	55.8	54.3	108.1

Conclusions: Our findings suggest that different dosing conversion requirements may be warranted depending on the type of organ transplant received. A higher percentage of African American and Hispanic patients in the AOT population may have led to higher dosing requirements of LCPT in this cohort. Organ type, age, and ethnicity should be taken into consideration when determining conversion ratios from IR TAC to LCPT. Further prospective research is needed to confirm these findings.

Abstract# 931

Belatacept Conversion in Elderly Renal Transplant Recipients

M. Durst[1], D. Felix[1], M. Jorgenson[1], J. Descourouez[1], B. C. Astor[2], D. Mandelbrot[2], *[1]UW Health, Madison, WI, [2]University of Wisconsin School of Medicine and Public Health, Madison, WI*

Purpose: Describe the impact of conversion from a calcineurin inhibitor (CNI) based immunosuppressive regimen to belatacept in elderly renal transplant recipients.

Methods: Adult renal transplant patients aged ≥ 60 years who were converted to belatacept from a CNI between 3/2013-6/2020 were included. Belatacept conversion was defined as CNI withdrawal or minimization (cyclosporine trough < 75 ng/mL or tacrolimus < 5 ng/mL) following belatacept initiation. Primary objective was to describe our experience with the safety of conversion defined as 6 month incidence of infection and malignancy. Secondary endpoints included efficacy defined as change in estimated GFR (eGFR), incidence of rejection, death-censored graft loss and death at last follow-up.

Results: Fifty-one patients met inclusion criteria, 86% with CNI withdrawal and 14% with minimization. Median time to conversion was 6.3 (IQR 2.3-20) months post-transplant with median follow-up of 12 (IQR 7-27) months. Mean age at time of conversion was 67 (SD 0.8) years. Conversion was pursued due to desire to improve renal function in 51%, neurotoxicity in 22% and metabolic/cardiovascular concerns in 16% of patients. Discontinuation of belatacept occurred in 27% of patients during follow-up. Primary reason for discontinuation was rejection (29%) followed by infection (21%). There were no instances of transplant lymphoproliferative disorder. However, 7.8% of patients experienced other malignancies. Thirty-nine percent of patients experienced at least one infection within 6 months of conversion with mean time from conversion to first infection of 1.8 (SD 0.4) months. Bacterial infections occurred in 27%, viral in 24%, and fungal in 2% of patients. eGFR significantly improved following belatacept conversion (31 ml/min/1.73m^2 pre vs 42 ml/min/1.73m^2 post; p = 0.002). Rejection occurred in 20% of patients at a median of 2 (IQR 1.9-2.7) months post conversion. There was a cumulative incidence of 5.7 death-censored graft losses per 100 person-years and 10.3 deaths per 100 person-years.

Conclusions: In our observational study, conversion from a CNI based regimen to belatacept in elderly renal transplant recipients resulted in improved eGFR. However, infection occurred in over a third of the population, which is at higher risk of infection due to age-related immune senescence, and rejection in a fifth of patients. The discontinuation rate was over 25%. Further studies evaluating safety, particularly infectious risk, in elderly patients converted to belatacept are warranted.

Abstract# 932

Avoiding Tacrolimus Under- and Overexposure with a Dosing Algorithm for Renal Transplant Recipients: A Single Arm Prospective Intervention Trial

M. I. Francke[1], L. M. Andrews[2], H. L. Le[2], J. van de Wetering[1], M. C. Clahsen-van Groningen[3], T. van Gelder[4], R. H. van Schaik[5], B. van der Holt[6], B. C. de Winter[2], D. A. Hesselink[1], *[1]Internal medicine, nephrology and transplantation, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [2]Hospital Pharmacy, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [3]Pathology, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [4]Clinical Pharmacy and Toxicology, Leiden University Medical Center, Leiden, Netherlands, [5]Clinical Chemistry, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [6]Hematology, Erasmus MC, University Medical Center, Rotterdam, Netherlands*

Purpose: Bodyweight-based tacrolimus dosing followed by therapeutic drug monitoring is standard clinical care after renal transplantation. However, after transplantation, a meagre 38% of patients is on target at first steady state and it can take up to three weeks to reach the target tacrolimus pre-dose concentration (C_0). Tacrolimus

under- and overexposure is associated with an increased risk of rejection and drug-related toxicity, respectively. To minimize sub- and supra-therapeutic tacrolimus exposure in the immediate post-transplant phase, a previously-developed dosing algorithm to predict an individual's tacrolimus starting dose was tested prospectively.
Methods: In this single-arm, prospective, therapeutic intervention trial, 60 *de novo* kidney transplant recipients received a tacrolimus starting dose based on a dosing algorithm instead of a standard, bodyweight-based dose. The algorithm included cytochrome P450 (*CYP*) *3A4* and *3A5* genotype, body surface area and age as covariates. The target tacrolimus C_0, measured for the first time at day 3, was 7.5-12.5 ng/mL.
Results: Between 23 February 2019 and 07 July 2020, 60 patients were included. One patient was excluded because of a protocol violation. On day three post-transplantation, 34 out of 59 patients (58%; 90%-CI 47% to 68%) had a tacrolimus C_0 within the therapeutic range. Markedly sub-therapeutic (<5.0 ng/mL) and supra-therapeutic (>20 ng/mL) tacrolimus concentrations were observed in 7% and 3% of the patients, respectively. Biopsy-proven acute rejection occurred in three patients (5%).
Conclusions: Algorithm-based tacrolimus dosing leads to the achievement of the tacrolimus target C_0 in as many as 58% of the patients on day three after kidney transplantation.

Abstract# 933

Calcineurin Inhibitor Dose and Selection, Not Antiproliferatives or Steroids, Influence Development of DSA One Year Post-kidney Transplant

M. Henderson[1], G. Morris[2], L. Awdishu[1], K. Fabbri[1], M. Shah[3], A. Khan[3], J. Kerr[1], *[1]Pharmacy, University of California San Diego Health, San Diego, CA, [2]Pathology, University of California San Diego Health, San Diego, CA, [3]Nephrology, University of California San Diego Health, San Diego, CA*

Purpose: Allograft rejection is a serious complication in kidney transplantation (KT). Despite advances in immunosuppression, acute rejection remains a concern in the first year of transplant. The incidence of donor-specific antibody (DSA) formation in approaches, such as steroid minimization, is undefined.
Methods: This retrospective, single center study, included patients who received KT between January 2017 and November 2019. Renal function, DSA formation, monthly median calcineurin inhibitor (CNI) levels, duration of goal dosing antiproliferatives, and monthly median steroid doses were recorded. DSAs were measured using single-antigen bead immunoassay with cutoff of 3000 MFI. The primary outcome was incidence of DSA formation within one year post KT. Secondary outcomes included incidence of DSA formation in patients on steroid minimization protocol, time at goal dose antiproliferatives, and trends in CNI concentrations.
Results: Patients (n=167) were followed for one year post KT. All patients received anti-thymocyte globulin (ATG) induction therapy (median dose of 4.2 mg/kg). Twenty-three (8%) patients developed DSA and median time to formation was 28 days (IQR 71 - 12). DSAs were predominantly against HLA Class II (78%). DSA formation did not differ based on ATG dose. At 3 months post KT, 33 patients (19%) were off steroids and did not develop DSA. There was no difference in incidence of DSA based on time at goal dose antiproliferatives. Twenty-seven patients transitioned from tacrolimus (FK) to cyclosporine (CsA) and 37% developed DSA compared to 9% in patients that remained on FK (P<0.001). Patients with DSA were less likely to be at goal dosing of CNI within the first month post KT (27% versus 55%; P = 0.02).
Conclusions: In summary, preventing DSA formation appears to be primarily influenced by CNI selection and levels. Steroid minimization or goal antiproliferative dosing had no effect on DSA. Critically, our data emphasize the importance of maintaining adequate CNI levels and caution when transitioning from FK to CsA.

Abstract# 935

Early Conversion to Belatacept-based Therapy Improves Graft Function in Renal Transplant Patients

N. Huang[1], C. J. Yang[2], I. Movileanu[1], R. H. Dvorai[3], K. M. Ecal[1], R. F. Saidi[1], A. N. Ayla Senay[1], B. Gallay[4], M. J. Hanlon[1], S. Narsipur[4], M. R. Laftavi[1], R. Shahbazov[1], *[1]Surgery, SUNY Upstate Medical University, Syracuse, NY, [2]Pharmacy, SUNY Upstate Medical University, Syracuse, NY, [3]Pathology, SUNY Upstate Medical University, Syracuse, NY, [4]Medicine, SUNY Upstate Medical University, Syracuse, NY*

Purpose: Our goal in this study was to assess the impact of early vs late conversion to Belatacept based (Bela) IS in kidney transplant (KT) recipients
Methods: We collected data on renal transplant recipients from 2016-2020 that were converted to a Belatacept-based IS regimen. Patients were stratified into an early-converted group if starting Bela therapy within 26 weeks of transplantation and late-conversion group if treatment was initiated after 26 weeks. Primary outcomes assessed graft function with estimate glomerular filtration rate (GFR). Secondary outcomes included serum creatinine (sCr) and glucose levels
Results: At our institute total 40 patients converted to Belatacept based IS (Image 1). Early conversion to Bela-therapy significantly enhanced graft function as measured by GFR. Early conversions had a significant increase in GFR from 19±5.3 mL/min to 40.0±6.8 mL/min by the ninth month (p=0.015) and 34.6±4.6 mL/min by the two-year mark (p=0.023). The late conversions had a higher baseline GFR of 38.6±3.8 that was saw little to no deviation over the two years ranging between 33 and 43 mL/min. (Image 1). Before conversion to Bela, average serum creatinine (sCr) was 3.12 (±0.38) and 2.06 (±0.17, p=0.0017) in the early and late groups, respectively. After conversion, the early group experienced a 33% decrease in sCr by the 2-year mark (p=0.0017) compared to their baseline values. Conversely, the late-converted group did not have significant deviations from respective baseline values prior to conversions. At 1, 6, and 24 months post-conversion, the early converted group saw significant improvements in sCr compared to the late converted group with sCr levels decreasing by 13% (p=0.04), 23% (p=0.015), and 38% (p=0.011), respectively.
There was no statistical significance between early and late conversion groups on metabolic glucose levels. There was no significant difference in the number of acute rejections between the two groups (early - 6 events or 29%, late - 5 events or 26%)
Conclusions: Our study has shown that early Belatacept conversion improves kidney graft function more effectively than later conversion. Therefore, early conversion to Belatacept based IS therapy may be considered more often in selected patients after kidney transplantation

	Early Conversion	Late Conversion	Total
Number of patients	21	19	40
Male	13	12	25
Female	8	7	15
Average Age (years)	59.4±2.0	56.0±3.3	
Average Time Before Conversion (Weeks)	12.0±1.4	160.7±25.4

Abstract# 936

Tolerability of De Novo and Conversion Belatacept Regimens in Kidney Transplantation

T. Le[1], J. Shoji[2], J. Phillips[1], D. Quan[1], *[1]Pharmaceutical Services, UCSF Medical Center, San Francisco, CA, [2]Transplant Nephrology, UCSF Medical Center, San Francisco, CA*

Purpose: Belatacept, a selective T lymphocyte co-stimulation blocker, has been shown to be a safe and effective maintenance therapy for immunosuppression. We investigated the long-term tolerability of belatacept in both de novo and conversion regimens in kidney transplant recipients.

Methods: This is a retrospective, single-center analysis of all kidney transplant recipients who received belatacept prior to June 30, 2020. We examined the length of time that patients received belatacept, reasons for discontinuation, estimated glomerular filtration rate (eGFR), and incidence of acute rejection.

Results: One-hundred and thirty-six patients were included in the analysis, 91 de novo (67%) and 45 conversion (33%). The median time from transplant to conversion was 4 months (IQR 1.9-6.1, range 0.4-122.9). Eighty-seven patients remained on belatacept, while 42 patients discontinued belatacept for the medical reasons shown in Table 1. There was no statistically significant difference in the rate of discontinuation between de novo and conversion groups (34.1% vs 40%, p = 0.57). In patients who stopped belatacept, the median time from the start of therapy to discontinuation was 3.9 months (IQR 2.2-5.6, range 0.2-151.7) in the de novo group vs 2.5 months (IQR 0.8-4.2, range 0.9-52.5) in the conversion group (p = 0.41). The mean eGFR at 1-year after starting belatacept was significantly higher in the de novo group (63.8 ± 34.4 mL/min/1.73 m2 vs 51.6 ± 16.8 mL/min/1.73 m2, p = 0.02). Figure 1 shows mean eGFR for up to 8 years. The rate of acute rejection at 1-year was similar between de novo and conversion groups (18.7% vs 22.2%, p = 0.65).

Conclusions: Belatacept was discontinued in a substantial number of patients for various medical reasons. Of these reasons, acute rejection was the most common. The length of time that patients received belatacept was similar between de novo and conversion patients, as were the rates of rejection. Patients started on belatacept de novo maintained a higher eGFR than those who were converted.

Table 1. Medical reasons for discontinuing belatacept

	De novo (n = 26)	Conversion (n = 16)
Acute rejection	17 (65.4%)	7 (43.8%)
Infection	2 (7.7%)	6 (37.5%)
Tolerability to regimen	5 (19.2%)	3 (18.7%)
Others	2 (7.7%)	-

Abstract# 937

Belatacept Utilization During the Covid-19 Pandemic in the United States

M. MacConmara, A. Shubin, D. Wojciechowski, L. de Gregorio, J. Shah, P. Vagefi, C. S. Hwang, *Department of Surgery, Division of Surgical Transplantation, University of Texas Southwestern Medical Center, Dallas, TX*

Purpose: With the onset of the COVID-19 pandemic, many people in the United States were urged to stay at home. Kidney transplantation continued during this time, albeit at a reduced pace. We examined if there was increased utilization of belatacept during the pandemic in fresh transplant recipients, as this would potentially decrease need for blood draws for monitoring medication troughs.

Methods: The UNOS STARfile was queried to examine all patients who received a kidney transplant between 3/1/2020 - 5/31/2020 (COVID era, COVID). All kidney transplants performed during 3/1/2019 - 5/31/2019 were defined as the pre-COVID era (Pre). In each era, patients were divided based upon belatacept (Bela) immunosuppression vs. non-belatacept (N) immunosuppression. The four groups examined included COVID/belatacept (COVID-Bela), pre-COVID/belatacept (Pre-Bela), COVID/non-belatacept (COVID-N), and pre-COVID/non-belatacept (Pre-N).

Results: There were 9563 transplants performed over both periods, of which 4171 (43.6%) were performed during COVID (118 or 2.8% COVID-Bela, 4053 or 97.2% COVID-N) and 5392 were performed pre-COVID (56.4%) (153 or 2.8% with Pre-Bela, 5239 or 97.2% Pre-N). Donor KDPI was significantly higher in both belatacept groups (57% COVID-Bela, 58% Pre-Bela vs. 44% COVID-N, 47% Pre-N, p<0.0001), along with a longer cold storage time (19.6 h COVID-Bela, 17.3 h Pre-Bela vs. 15.1 h COVID-N, 13.7 Pre-N, p<0.0001) and higher donor creatinine (1.66 mg/dL COVID-Bela, 1.63 mg/dL Pre-Bela vs. 1.33 mg/dL COVID-N, 1.32 mg/dL Pre-N, p<0.002). Recipients in the belatacept groups were also significantly older (55.8 y COVID-Bela, 55.2 y Pre-Bela vs. 51.9 y COVID-N, 52.9 y Pre-N, p<0.0001), had a higher EPTS (0.53 COVID-Bela, 0.50 Pre-Bela vs. 0.46 COVID-N, 0.47 Pre-N, p=0.03), higher creatinine at discharge (5.68 mg/dL COVID-Bela, 4.37 mg/dL Pre-Bela vs. 4.20 mg/dL COVID-N, 3.74 mg/dL Pre-N, p<0.0001), and greater delayed graft function (DGF) (42.4% COVID-Bela, 30.7% Pre-Bela vs. 23.1% COVID-N, 23.2% Pre-N, p<0.0001). Regions 3, 4, and 5 had the greatest utilization of belatacept during the COVID era at 29.7%, 25.4%, and 8.5%, respectively.

Conclusions: Despite stay at home recommendations, utilization of belatacept did not increase during the COVID era. Belatacept immunosuppression continued to be used in higher KDPI kidneys in older recipients as had been done in the pre-COVID era. Transplantation during COVID brought longer cold storage times and greater DGF, but belatacept potentially has allowed utilization of kidneys that might have otherwise been discarded during the COVID era.

Abstract# 938

Association of Belatacept Conversion on Patient and Allograft Survival in Kidney Transplant Recipients with Congestive Heart Failure

H. Mogallapalli, *Department of Medicine, University of Wisconsin-Madison, Madison, WI*

Purpose: Calcineurin inhibitors (CNI) exert deleterious effect on cardiovascular risk in kidney transplant recipients (KTRs). Belatacept conversion may reduce CV risk in KTRs. We hypothesized that early conversion to Belatacept will have better patient and graft survival and lower rate of readmission within 30-days in KTRs with congestive heart failure (CHF) compared to long-term CNI use.

Methods: We merged Belatacept dataset in Wisconsin Allograft Recipient Database with Clarity Healthlink dataset which contain admitted recipients with CHF between 2014-2019 using ICD-10 Code I50 for CHF and E87.70 for volume overload. Subjects switching to Belatacept were divided into Early Conversion (EC: switched to Belatacept within one year from transplant) and Late Conversion (LC: switched after one year). The Greedy matching was used for the EC and LC participants based on transplant date in a 1:2 allocation ratio to CNI control subjects (CNI-c).

Results: Of the 301 patients in the study, EC accounted for 31.5% (n=97), LC 25.1% (n=77), and CNI-c 43.3% (n=133). The median patient survival (years, IQR): CNI-c (2, 2.3), EC (2.2, 1.8) and LC (3.4, 2.4) (p<0.001). There was no significant difference in the prevalence of history of MI, CHF and CAD at time of transplant. Mean time to switching was 3.36 months and 3.5 years for EC and LC, respectively. Compared to Belatacept groups, CNI-c had significantly higher rate of Basiliximab induction (p=0.001), were more likely to have received deceased donor transplant (p=0.05) and had significantly younger donor age (43.2 years, p=0.04). Adjusted hazard ratios (aHR) showed no statistical difference for patient and graft survival between the three groups. However, conversion to Belatacept was associated with better numerical patient and graft survival (aHR 0.36, 95% CI [.03-3.8], p=0.4)

and (aHR 0.74, 95% CI [0.1-7.2], P=0.8), respectively. There was no significant difference in readmission within 30-days rate (18%, 11% and 15%, p=0.32) among CNI-c, EC and LC, respectively.

Conclusions: Patient and graft survival and rate of readmission within 30-days post CHF hospital discharge were not significantly different among the three groups. However, the patient and graft survival rates do suggest clinically protective effects of converting patients to Belatacept after transplant date.

Abstract# 939

Modeling of Alternative Weight-Based Dosing Strategies of LCP-Tacrolimus in De Novo Kidney Transplant Patients

J. D. Momper[1], S. J. Patel[2], M. A. Moten[2], D. R. Stevens[2], U. Meier-Kriesche[2], *[1]Skaggs School of Pharmacy and Pharmaceutical Sciences, University of California San Diego, La Jolla, CA, [2]Medical Affairs, Veloxis Pharmaceuticals, Cary, NC*

Purpose: LCP-tacrolimus (LCPT; Envarsus XR®) is a modified-release once-daily formulation approved for prophylaxis of organ rejection in de novo kidney transplant patients in combination with other immunosuppressants. A phase 3 study of LCPT initiated at a dose of 0.17 mg/kg/day resulted in trough concentrations >12ng/mL in 36.5% of recipients after the first dose. The objective of this study was to simulate alternative weight-based dosing strategies of LCPT in this population, using the recommended starting dose per product labelling: (i) 0.14 mg/kg actual body weight (ABW), (ii) 0.14 mg/kg ideal body weight (IBW), (iii) 0.14 mg/kg ABW with a dose cap of 12 mg.

Methods: The initial dose of LCPT was given within 48 hours of transplantation. First dose trough concentrations for each alternative dosing scenario were simulated by proportional scaling of actual dose received and observed trough concentration, as follows

$$\text{Predicted first trough} = \frac{\text{Observed first trough (Alternative dosing regimen)}}{\text{Actual dose received}}$$

For each dosing scenario, the proportion of subjects with a predicted first tacrolimus trough concentration <3, 3 - 6, 6 - 9, 9 - 12, 12 - 15, and >15 ng/mL was determined.

Results: A total of 266 de-novo kidney transplant patients were included. The median (interquartile range; IQR) age, actual body weight, ideal body weight, and actual dose received were 46 years (35 - 55 years), 73.0 kg (62.5 - 87.0 kg), 63.5 kg (55.4 - 71.4 kg), and 13 mg (10 - 15 mg). The proportion of subjects with a predicted trough concentration within each bin are shown in the Table.

Proportion of subjects (n=266) with a predicted trough conc based on dose modeling strategies.

First trough concentration (ng/mL)	0.17 mg/kg ABW (observed)	0.14 mg/kg ABW	0.14 mg/kg IBW	0.14 mg/kg ABW with dose cap of 12 mg
<3	5.3%	9.3%	12.0%	9.3%
3 to 6	20.5%	22.0%	29.7%	23.2%
6 to 9	19.4%	27.4%	22.4%	27.4%
9 to 12	18.3%	12.4%	15.1%	12.4%
12 to 15	9.1%	11.6%	8.1%	10.4%
>15	27.4%	17.4%	12.7%	17.0%

Conclusions: Alternative LCPT dosing strategies may result in a greater proportion of therapeutic first-dose trough concentrations in de-novo kidney transplant patients. In particular, dosing LCPT based upon IBW is predicted to reduce the likelihood of supratherapeutic first-dose trough concentrations.

Abstract# 940

Evaluation of Empiric Extended-Release Tacrolimus Dosing in Adult Kidney Transplant Recipients

C. Patel, S. Lee, D. M. Salerno, N. W. Lange, J. Hedvat, *Pharmacy, NewYork-Presbyterian Hospital, New York, NY*

Purpose: Envarsus XR® (extended-release [XR] tacrolimus) is the standard of care tacrolimus formulation at our center for *de novo* maintenance immunosuppression in adult kidney transplant recipients (KTR). At our center, KTR empirically begin XR tacrolimus at a dose of 0.12 mg/kg/day. The purpose of this study is to evaluate weight-based dosing requirements at various times post-transplant.

Methods: This was an IRB-approved, single center retrospective analysis of adult patients who received a KT between 07/2019-07/2020. Patients were excluded if they received formulations other than XR tacrolimus or received medications known to interact with tacrolimus within the first two weeks following KT. The primary endpoint was the weight-based XR tacrolimus dose at first therapeutic tacrolimus trough level, defined as at least 2 consecutive trough levels between 8-12 ng/mL. Secondary endpoints included weight-based XR tacrolimus dose at postoperative days (POD) 7 and 14, and time to therapeutic tacrolimus trough level. Additional sub-group stratifications for sex, race, and weight were evaluated.

Results: A total of 141 KTR were identified. Median patient age was 57 (46-64) years. Patients were predominantly male (60%) and white (45%). Median BMI was 26.9 (22.3-30.5) kg/m^2. A total of 67 patients achieved a therapeutic tacrolimus trough level within the first 14 days following KT. Median weight-based XR tacrolimus dose at first therapeutic tacrolimus trough level was 0.12 (0.11-0.14) mg/kg/day and the median time to therapeutic trough level was 5 (4-9) days (Figure 1A and B). Median weight-based therapeutic XR tacrolimus doses on PODs 7 and 14 were 0.13 (0.1-0.17) and 0.13 (0.09-0.17) mg/kg/day, respectively. Median therapeutic weight-based XR tacrolimus dose for male patients was 0.13 (0.11-0.17) versus 0.12 (0.1-0.13) mg/kg/day for female patients (p=0.033). In patients with a BMI of <24, 24-29, and >29 kg/ m^2, the median therapeutic weight-based XR tacrolimus dose was 0.14 (0.12-0.17), 0.11 (0.1-0.14), and 0.12 (0.1-0.14) mg/kg/day, respectively (p=0.022). The therapeutic dose was 0.12 (0.1-0.15) for patients who were Caucasian, African American, Asian, and other ethnicities and 0.13 (0.12-0.18) for Hispanic patients (p=0.796).

Conclusions: XR tacrolimus starting doses of 0.12 mg/kg/day allowed for attainment of goal tacrolimus trough blood levels in most patients following KT. Accounting for patient gender and BMI when dosing XR tacrolimus may permit earlier achievement of therapeutic trough blood levels, however additional study is required to further evaluate this.

Abstract# 941

Obesity Impacts Acute Rejection but Not Allograft Function Improvement in the Setting of Belatacept Conversion

D. Pierce, J. Benken, P. West-Thielke, I. Tzvetanov, E. Benedetti, A. Lichvar, *University of Illinois at Chicago, Chicago, IL*

Purpose: There is limited data regarding belatacept conversion in obese patients as an alternative to calcineurin inhibitor (CNI) immunosuppression. Pharmacokinetic (PK) data suggests increasing clearance and volume of central/peripheral compartments with increasing body weight. The purpose of this study is to compare rejection, allograft function, and infectious outcomes of obese versus non-obese renal transplant (RT) recipients converted to belatacept.

Methods: Adult RT recipients between 3/1/2018 - 5/30/2020 at the University of Illinois Hospital & Health Sciences System converted to belatacept were assessed. Patients who received multiorgan transplants or were lost to follow up were excluded. Belatacept was initiated at 10mg/kg on days 1, 5, 14, 28, and then every 4 weeks until week 16 where patients received 5mg/kg every 4 weeks. CNIs were tapered to discontinuation over 8 weeks. All patients were started on prednisone 10mg at conversion. Obese (body mass index [BMI] > 35 kg/m^2) and non-obese patients were compared. High immunologic risk was defined as PRA > 10%, presence of DSA at RT, and positive XM. Acute rejection (defined as biopsy proven acute rejection (BPAR) or empiric rejection treatment) was compared. Allograft function (measured by eGFR), BK viremia, CMV viremia, death-censored allograft survival, and patient death were also analyzed.

Results: A total of 38 RT recipients were included (25 [65.7%] non-obese patients and 13 [34.2%] obese patients (Table 1). Belatacept conversion occurred at a median of 48 days (IQR 24 - 127 days) post-transplant for predominantly nephrotoxicity/nephroprotection (78.9%). Acute rejection was significantly higher in obese patients after belatacept conversion (non-obese 12% vs obese 46.2%, p=0.019). Table 2 details rejection and allograft function. Figure 1 illustrates time to acute rejection survival curve analyses. Despite this there was no difference in eGFR. Incidence of post-transplant viremias were similar (Table 2).

Conclusions: Acute rejection was observed more frequently in the obese RT cohort without impact to allograft function. More studies examining the PK and clinical outcomes of belatacept in obese patients is warranted.

TABLE 1. Demographics, Immunosuppression, and Belatacept Conversion in formation

Variable	Overall (n=38)	Non-Obese (n=25)	Obese (n=13)	p-value

Abstract# 942

Kidney Transplant Outcomes Stratified by Race with a Calcineurin and Steroid Free Regimen

R. E. Scalzo, M. T. Harris, J. D. Morris, J. S. Byrns, *Pharmacy, Duke University Medical Center, Durham, NC*

Purpose: This study aimed to describe the outcomes, stratified by race, associated with belatacept and sirolimus immunosuppression after alemtuzumab induction.

Methods: This was a retrospective, single-center study analyzing the outcomes of kidney transplant recipients who received belatacept-sirolimus after alemtuzumab induction. To be included, patients must have received a kidney-only transplant between 1/1/2016 and 8/31/2019, be >/= 18 years old, and be EBV seropositive. The primary outcome was renal function (GFR by MDRD or CKD-EPI) at 1 year. Secondary outcomes were renal function at 3, 6, and 9 months, incidence of biopsy proven rejection (BPAR), patient/graft survival, incidence of infection and malignancy, and medication tolerability.

Results: Fifteen African American (AA) and 26 non-AA patients were included. The cohorts were well-matched, except for more deceased donor recipients and longer cold ischemic times in the AA cohort (see figure 1). At 1 year, median GFR was 60 mL/min in the AA cohort and 55.5 mL/min in the non-AA cohort (p=0.82) (see figures 2 and 3). Patient/graft survival was 100% overall. BPAR occurred in 3 patients (20%) in the AA group, 1 due to non-adherence and 1 to a decrease in immunosuppression due to BK viremia. No BPAR was seen in the non-AA group. Mouth ulcers and leukopenia were the most common ADRs (40% vs 46.2% and 20% vs 53.8%, respectively). Infection rates were similar between groups with CMV (6 patients in each) and BK viremia (3 vs 1 patient, respectively).

Conclusions: No significant differences between the AA and non-AA cohort were found in GFR at 1 year. Rejection occurred in 20% of patients, which is similar to prior studies with belatacept. The medication regimen was well tolerated with excellent patient/graft survival. In conclusion, race did not impact renal outcomes in patients who received this belatacept-based regimen.

Abstract# 943

Kidney Transplant Outcomes Stratified by Age with a Calcineurin and Steroid Free Regimen

R. Scalzo[1], M. Harris[1], J. Morris[2], J. Byrns[1], *[1]Pharmacy, Duke University Hospital, Durham, NC, [2]Nephrology, Duke University Hospital, Durham, NC*

Purpose: To evaluate the impact of an alemtuzumab, belatacept, and sirolimus based regimen on renal function stratified by age in kidney transplant (KT) patients.
Methods: This was a single center, retrospective analysis of KT patients receiving alemtuzumab for induction with denovo belatacept/sirolimus between 2016-2019. Cohorts included patients who were <55 years old (yo) versus >/=55 yo, received a KT alone, were >/=18 years, and EBV seropositive. The primary endpoint was GFR (MDRD or CKD-EPI) at 12 months (m). Secondary endpoints were GFR at 3, 6, 9m, incidence of biopsy proven acute rejection (BPAR), patient/graft survival at 12m, incidence of malignancy and infection, and medication tolerability. Descriptive statistics were performed.
Results: Forty one patients (n=27 in <55 yo and n=14 in >/=55 yo) were included. Baseline demographics were similar between groups (figure 1) except for age. GFR at 12m was similar (51.5 ml/min vs 57.5 ml/min, respectively, p=0.32) (figure 2 and 3). Serum creatinine at 12m was higher in the <55 yo group (1.5 vs 1.1, respectively, p=0.02). BPAR and patient/graft survival were not different between groups. CMV viremia occurred in 6 patients in each group (22.2% vs 42.9%, respectively) and BK viremia occurred in 8 patients in the <55 yo group versus 3 in the >/=55 yo group. The most common infection was urinary tract infections (18.5% vs 14.3%, respectively). Malignancy occurred in 1 patient. The medication regimen was well tolerated with mouth ulcers (40.7% vs 42.9%, respectively) and leukopenia (66.7% vs 71.4%, respectively) as the most common ADR.
Conclusions: Renal function by MDRD was preserved in both groups regardless of age in those receiving a maintenance regimen of belatacept/sirolimus after alemtuzumab induction. The regimen was well tolerated with excellent patient/graft survival.

Abstract# 944

Sharp Anti-HLA Antibody Development Due to Concomitant Graft Nephrectomy and Immunosuppression Withdrawal After Early Graft Loss

R. Valero[1], A. Aguilera[1], E. Rodrigo[1], D. San Segundo[2], M. Lopez-Hoyos[2], J. Ruiz[1], *[1]Nefrología, Hospital Universitario Marqués de Valdecilla, Santander, Spain, [2]Inmunología, Hospital Universitario Marqués de Valdecilla, Santander, Spain*

Purpose: The number of patients awaiting for retransplantation has been progressively increasing. The presence of anti-HLA antibodies can significantly lengthen the waiting time, limiting the access for a new transplant and increase the risk of graft rejection and failure. Risk factors for HLA sensitization are withdrawal of immunosuppression (IS) and graft nephrectomy (GN). GN is usually a non-elective procedure performed after early graft loss, mostly related to surgical complications or severe rejection. Currently there is no consensus on the discontinuation of immunosuppressive therapy after early graft nephrectomy.

Methods: Between 2014 and 2020 17 kidney grafts were removed at our center after early loss due to vascular thrombosis or bleeding. In 15 isolated kidney transplants (IKT), tacrolimus and mycophenolate were immediately withdrawn after GN and steroids were tapered in two weeks. In 2 simultaneous pancreas-kidney transplants (SPK) IS was maintained to preserve pancreas graft function. Anti-HLA antibodies were tested six months after graft loss using *Single Antigen* test. Calculated panel-reactive antibody (cPRA) was estimated using Virtual PRA Eurotransplant Calculator.

Results: Pretransplant cPRA was 0% in all recipients but one (43%). Median cPRA 6-mo after GN was 98% (IQR 93%-99%), whereas both SPK transplants remained at 0%. Median difference between pretransplant and 6-mo post GN cPRA was 98% (IQR 54%-99%). Only 3 patients (20%) had a cPRA below 50% at the end of the study period (isolated kidney graft). Age, gender or induction therapy did not relate to development of anti-HLA antibodies (p = 0.712) whereas the presence of 2 DR-mismatches showed a higher trend to increased cPRA (98%±2% *vs* 57%±44%, p=0.072). Neither age nor gender related to a higher increase of cPRA.

Conclusions: Early GN with rapid IS elimination is associated with almost universal severe HLA sensitization. This effect might be a direct consequence of IS elimination as it is not observed when IS is maintained. This fact should be considered when a new kidney transplant might be an option in the short/mid-term. Risk/benefit balance of IS maintenance on dialysis should be evaluated and it might be beneficial in selected cases.

Abstract# 945

Tolerability of Mycophenolate Mofetil in Elderly Kidney Transplant Recipients: A Retrospective Cohort Study

S. Witek[1], G. Malat[2], D. Sawinski[2], C. Sammons[2], C. LaFratte[1], A. Forte[1], R. Samudralwar[1], S. Lyle[1], J. Rashid[1], J. Trofe-Clark[2], *[1]Dept of Pharmacy, Hospital of the Univ of Pennsylvania, Philadelphia, PA, [2]Penn Transplant Institute, Hospital of the Univ of Pennsylvania, Philadelphia, PA*

Purpose: Optimal immunosuppression in elderly kidney transplant recipients (KTRs) is not well-defined, with MMF being poorly tolerated at standard doses. This study aims to compare MMF dose reduction incidence and reason(s) in elderly vs. non-elderly KTRs in the first yr after transplant with a protocol dose of 1g/day.

Methods: In this IRB-approved, single-center retrospective cohort study, KTRs receiving rabbit antithymocyte globulin (rATG) induction, MMF 1g/day, tacrolimus, and prednisone, with ≥ 6 mos f/u were stratified by age [≥ 60 (elderly) or < 60 yrs (non-elderly)]. Only 1st or 2nd KTRs alone were considered. Primary outcome was MMF dose reduction incidence in the first yr, reviewed at defined intervals. Secondary outcomes include the indication for dose reduction, 1-yr patient/graft survival, and graft function.

Results: An interim analysis included 133 KTRs (elderly n=51, non-elderly n=82). Groups were similar in demographics except for more living donors and lower kidney donor profile index (KDPI) in the non-elderly group (Table 1). MMF dose reductions occurred in 32 elderly and 50 non-elderly KTRs during the first yr (61% vs 63%, p=0.86) for reasons mentioned in Table 2. Most dose reductions occurred within 2 mos (elderly 31% vs. non-elderly 32%) with nearly all occurring between mos 2-6 (84% and 82%). At 1 yr, 47% elderly and 49% non-elderly were on MMF 1g/day (p=0.86), 6% and 13% were on 500mg/day (p=0.25), and 45% and 35% were on 0mg/day (p=0.28). There were no differences in 1-yr patient/graft survival or graft function.

Table 1: Baseline Characteristics

Characteristic	Elderly (N=51)	Non-elderly (N=82)	p-value
Age, median (IQR)	64 (61-67)	47 (38-52)	< 0.005
Prior kidney transplant, n (%)	2 (3.9)	7 (8.5)	0.48
Female, n (%)	22 (43.1)	35 (42.7)	1
Caucasian, n (%)	31 (60.8)	49 (59.8)	1
Dialysis pre-transplant, n (%)	37 (72.5)	62 (75.6)	0.69
Deceased donor, n (%)	36 (70.6)	42 (51.2)	0.03
KDPI, median (IQR)	52 (40-74)	37 (20-59)	0.01
DGF, n (%)	20 (39.2)	21 (25.6)	0.12

Table 2: Reasons for MMF Dose Reduction

Rationale	Elderly (n=32) n (%)	Non-elderly (n=50) n (%)	p-value
Gastrointestinal	9 (28)	9 (18)	0.29
Leukopenia (WBC < 3k/mcL)	11 (34)	30 (60)	0.08
BK virus	5 (16)	4 (8)	0.30
CMV	4 (13)	1 (2)	0.07
Non-opportunistic infection	0	3 (6)	0.28
Other	3 (9)	3 (6)	0.68

Conclusions: In this interim analysis, there was no difference in MMF dose reduction incidence between elderly vs non-elderly KTRs using 1g/day with rATG induction. Most dose reductions occurred in the first 6 mos post-transplant. The elderly KTR group more commonly required MMF dose reductions secondary to GI side effects and viral infections, including BK and CMV, although not statistically significant. Continued data collection/analysis is necessary to further elucidate this trend.

Abstract# 946

Tacrolimus Variability Score Outperforms Coefficient of Variation in Predicting Clinical Outcomes of Living Kidney Transplantation

S. Yin, T. Song, Q. Zhong, T. Lin, *Urology Institute and Organ Transplantation Center, West China Hospital, Chengdu, China*

Purpose: Intra-patient variability (IPV) was previously defined as coefficient of variation (CV) or standard deviation of Tacrolimus (Tac) exposure while none of them was easily being interpreted and translated into clinical practice after kidney transplantation (KT).

Methods: We developed a novel Tac variability score (TVS) to evaluate IPV by calculating the frequency of clinically significant changes of Tac trough levels after KT. Multivariate Cox proportional analyses were conducted to compare the impact of TVS and CV on transplant outcomes.

Results: A total of 1343 patients were divided into high TVS (>0.30) and low TVS (<0.30) groups, and low CV (<0.30) and high CV (>0.30) groups. Univariate analyses showed that high TVS (HR: 2.323, 95%CI: 1.455-3.709) and high CV (HR: 1.606, 95%CI: 1.044-2.471) were associated with inferior graft survival. However, only TVS was an independent predictor for graft failure in multivariate analyses (HR: 1.972, 95%CI: 1.2-3.24), and the correlation maintained in high CV (P=0.020) and low CV (P=0.037) subgroups, while CV failed to predict graft loss in neither low

(P=0.387) nor high TVS (P=0.600) subgroups. In addition, TVS had a higher correlation with graft survival in patients with Tac exposure within the therapeutic range and the correlation was less influenced by mean Tac trough levels.

Conclusions: TVS is a novel measure of Tac IPV with higher correlation with graft survival and more convenience in clinical use than CV after kidney transplantation.

Kidney

Kidney Living Donor: Long Term Outcomes

Abstract# 947

Frailty Component Trajectories Among Kidney Transplant Recipients

N. Chu, X. Chen, D. Segev, M. McAdams-DeMarco, *Johns Hopkins, Baltimore, MD*

Purpose: Frailty is associated with decreased access to kidney transplantation (KT) and poor post-KT outcomes. Little is known about how an acute stressor, like KT, can impact the five physical frailty phenotype (PFP) criteria.

Methods: We conducted a two-center prospective cohort study (2009-2019) of adult patients undergoing KT. PFP criteria were measured at KT admission, 1 month, 3 months, 6 months, 1 year, and annually thereafter post-KT. We used adjusted mixed effects models with fixed and random effects for person and time to describe repeated measures of continuous criteria components (weight, gait speed, grip strength, activity). We used an adjusted generalized estimating equation to quantify longitudinal, binomial response patterns of exhaustion.

Results: Among 1,410 KT recipients (mean age=53) followed for a mean of 1.9 years (IQR=0.1-3.2), 46.3% had low activity, 46.6% weakness, 28.9% exhaustion, 16.2% slowness, and 14.2% unintentional weight loss at KT admission. Among continuous components, weight worsened (0.4lb/month, 95%CI:0.3,0.5), while grip strength (0.16kg/month, 95%CI: 0.13,0.19) and activity (23.9Kcal/month, 95%CI:17.5,30.2) improved post-KT; gait speed remained stable (-0.005s/month, 95%CI:-0.01,0.003). Additionally, recipients were less likely to transition to being exhausted (OR=0.99, 95%CI:0.98,1.00). Weight trajectories differed by age, such that older recipients (≥65years) experienced weight gain (0.5lb/month,95%CI:0.4,0.6), while younger recipients (<65years) remained stable (0.1lb/month,95%CI:-0.1,0.3; p-interaction=0.003).

Conclusions: After undergoing a common surgical stressor, KT recipients demonstrated weight gain as well as improvements in strength and activity. Despite benefits of restoration of kidney function, clinicians should consider monitoring KT recipients for persistent weight gain and slowness post-KT, particularly among older adults.

Table. Adjusted estimates of frailty components trajectories post-KT overall and by age among kidney transplant (KT) recipients (n=1,410). Mixed effects models for continuous components (weight, grip strength, gait speed, activity) and generalized estimating equations for dichotomous components (exhaustion) were used to estimate level and change of each frailty component in separate models. All models were adjusted for age, sex, race, cause of ESKD, years on dialysis, diabetes status, and donor type. Intergroup differences and monthly changes that are statistically significant at p<0.05 are bolded.

Subgroup	Level (95% CI)			Monthly change (95% CI)

Abstract# 948

Different Levels of GFR of Retained Kidney on the Long-term Safety of the Donors in Living-related Renal Transplantation

M. Dou, P. Tian, B. Zheng, G. Deng, Y. Shi, C. Ding, *The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*

Purpose: To summarize the long-term safety of different levels of GFR of retained kidney among living-related donors.Health status,postoperative recovery,and postoperative complications were compared and analyzed.

Methods: A total of 512 living donors in our kidney transplantation center from 1999 to 2018 were enrolled into this study.The donors were divided into three groups according to donor retained kidney GFR level(GFR<45ml/min;45ml/min≤GFR<50ml/min;GFR≥50ml/min).The predonation retained kidney GFR was measured by 99mTC-DTPA.The recovery of kidney function and complications of the donor after surgery were evaluated.

Results: 163 donors were excluded because of incomplete data.A total of 349 cases were included in this study,All donors were healthy with no kidney failure.The longest postoperative follow-up time was 20 years,The median follow-up time was 8.3 years.No significant difference was observed in the incidence of postoperative hypertension and urine protein among the three groups of donors.The postoperative Scr of GFR≥50ml/min group at 1 week,1month,3 months,3 years,5 years,10 years was higher compared with the GFR<45ml/min group,and the difference of Scr and eGFR at 1 week,3 months was significantly different(P<0.05).The GFR(measured by 99mTC-DTPA)of three groups of donors more than 10 years were not significantly different.

Conclusions: Living-related donors have good long-term safety after donation.For donors with preoperative total GFR≥80ml/min,the level of retained renal GFR affects the donor's early renal function ,while donors with high retained kidney GFR have higher eGFR level and lower Scr level ,but the donor's retained renal GFR level does not affect the donor Long-term renal function and complication rate after donation.

Abstract# 949

Factors Affecting Sensitization Following Kidney Allograft Failure

N. Garg, L. Hidalgo, S. Parajuli, F. Aziz, M. Mohamed, A. Djamali, D. Mandelbrot, *UW Madison, Madison, WI*

Purpose: Kidney transplant (KT) recipients with failed allografts constitute nearly 12% of the current waitlist in the US. Sensitization as a result of graft failure (GF) leads to longer wait-times and lower repeat KT rates. In addition, repeat KT in the setting of preexisting DSA may contribute to worse outcomes. This study explored factors affecting sensitization following GF.

Methods: Inclusion criteria included 1) index KT between 7/2009 and 6/2019, 2) GF between 1/2016 and 6/2020, and 3) repeat transplant evaluation including cPRA analysis after GF. The most recent available cPRA value was used for analysis. Among those with pre-index KT cPRA of ≤ 50, analyses were done to identify risk factors for 1) increase in cPRA (delta cPRA) of ≥ 50-points, and 2) sensitization to cPRA of ≥ 98.

Results: 55 KTs, 14% of which were simultaneous pancreas kidney transplants, met our inclusion criteria. Median (range) pre-index KT cPRA was 0 (0-100), post-GF cPRA was 85 (0-100), and time from GF to most recent cPRA was 14.5 months (1.5-50.8). Most patients were on triple immunosuppression prior to GF. Steroids were continued in 85%, calcineurin inhibitor (CNI) in 58%, and antimetabolite in 31%. Among 45 KTs with pre-transplant cPRA ≤ 50, univariate analysis showed that those with delta cPRA ≥ 50 were less likely to be SPK recipients (4% vs 32%, p=0.02), and less likely to have been continued on steroid (65% vs 100%, p=0.004), CNI (30% vs 86%, p<0.001), or antimetabolite after GF (17% vs 50%, p=0.03). There was no difference in age, sex, race, blood type, ESKD etiology, HLA mismatches, induction or maintenance immunosuppression, time from transplant to GF or nephrectomy rates between the two groups. Ongoing CNI use after GF was protective against delta cPRA ≥ 50 (Odds ratio (OR) 0.12, p=0.02), and benefit associated with ongoing steroid approached statistical significance (OR 0.13, p=0.07). Using delta cPRA as a continuous variable, linear regression modeling yielded similar results for ongoing CNI use (p=0.003) and ongoing steroid use (p=0.03). In another analysis evaluating sensitization to cPRA ≥ 98, ongoing CNI use was the only protective variable (OR 0.07, p=0.009).

Conclusions: Continuing CNI and steroids are associated with significantly lower risk of sensitization after kidney allograft failure. CNIs appear to be particularly important in preventing sensitization to cPRA ≥ 98.

Abstract# 950

Pill Burden in Belatacept versus Tacrolimus-Based Immunosuppression

S. Gattis, L. Lakhani, A. Basu, *Emory Healthcare, Atlanta, GA*

Purpose: Medication non-adherence is a major barrier amongst renal transplant recipients, and improvement can be seen after reduction in pill burden. Belatacept versus tacrolimus-based immunosuppression has shown renal preservation and improved cardiovascular and metabolic outcomes. We aimed to compare the daily pill burden in patients on belatacept versus tacrolimus-based regimens.

Methods: We performed a single center retrospective analysis of kidney transplant recipients who were transplanted January 2017 through January 2019. Patients with failed allograft, death, or <1 year of follow-up were excluded from the study. Using t-tests and ANOVA, we compared 4 groups based on immunosuppression regimen: belatacept, tacrolimus, tacrolimus to belatacept conversion, and belatacept to tacrolimus conversion.

Results: 432 patients were included in this study: belatacept (n=74), tacrolimus (n=330), conversion to belatacept (n=21), and conversion to tacrolimus (n=7). All groups were similar in demographics. (TABLE1). The number of oral medications and daily pill burden at discharge was similar across all groups. A significant reduction in number of medications [Median 8 (IQR 6-11) pills, **p 0.001**] and pill burden [Median 11(IQR 9-15) pills, **p<<0.001**] was observed amongst recipients on belatacept. A reduction in number of medications [Median 7(IQR 5-9) pills, **p 0.001**] and daily pill burden [Median 11 (IQR 7-15) pills, **p<0.001**] was also observed in patients converted from tacrolimus to belatacept. Reduction in pill burden in belatacept groups was seen even if stratified by age group (Table 2).

TABLE 1.Characteristics by immunosuppression protocol

Total N=432	Belatacept (n=74)	Tacrolimus (n=330)	Conversion to belatacept (n=21)	Conversion to tacrolimus (n=7)	p-value
Median Age (IQR)	53(43-60)	51(42-59)	46(38-66)	50(40-58)	0.67
Male (%)	41	196	2	15	0.37
Black (%)	38	176	3	11	0.45
Time to Follow up(IQR)	22(18-38)	28(24-34)	29(23-35)	35(23-37)	0.25
Post-transplant					
Median Number or medications	12(10-13)	12(10-13)	11(9-13)	13(11-14)	0.16
Daily Pill Burden	19(16-23)	21(17-25)	18(15-22)	18(17-23)	0.03
At last visit					
Median Number or medications	8(6-11)	10(8-12)	7(5-9)	11(10-13)	**0.001**
Daily Pill Burden	11(9-15)	17(13-20)	11(7-15)	22(17-28)	**<0.001**

TABLE 2. Pill burden at follow up by age (IQR)

	Belatacept	Tacrolimus	Conversion to belatacept	Conversion to tacrolimus	p-value
<40 yrs	10 (6-11)	15 (11-18)	15 (10-17)	22 (18-25)	**0.003**
40-60 yrs	12 (10-15)	17 (13-21)	9 (7-14)	16 (12-19)	**<0.001**
>60 yrs	13 (11-18)	17 (14-22)	13 (12-14)	27 (24-29)	**0.005**

Conclusions: Belatacept should be the immunosuppression of choice amongst all eligible kidney transplant recipients to reduce pill burden and potentially improve medication adherence.

Abstract# 951

Creatinine Reduction Ratio at 2 Postoperative Day as a Predicting Factor of Long-Term Outcomes After Living Donor Kidney Transplantation

Y. Kinoshita, T. Shinzato, T. Shimizu, D. Iwami, *Division of Renal Surgery and Transplantation, Department of Urology, Jichi Medical University Hospital, Shimotsuke, Tochigi, Japan*

Purpose: Creatinine reduction ratio from 1 to 2 postoperative days (CRR2) under 30% has been defined as a slow graft function (SGF) and used to predict long-term graft outcomes in some studies involving deceased donor kidney transplantation. However, the usefulness of the parameter involving living donor kidney transplantation (LDKT) remains uncertain. We retrospectively evaluated the relationship between CRR2 and graft survivals after LDKT and the risk factor for SGF.

Methods: Clinical data on patients who underwent LDKT at Jichi Medical University Hospital in 2006-2019 were extracted from the medical records. After excluding patients who needed reoperation, dialysis, or anti-rejection therapy within 1 week after transplantation, patients were divided into 2 groups: immediate graft function (IGF) defined as patients with CRR2 > 30%, and SGF defined as patients with CRR2 ≤ 30%. CRR2 was calculated by the formula: (Cre1 - Cre2)×100/Cre1 (Cre1 and Cre2 refered serum creatinine level 1 and 2 postoperative days after transplantation).

Results: Of the 272 patients, 242 were IGF group and 30 were SGF group. Regarding the relationship between CRR2 and graft survivals, the log-rank test and multivariate Cox proportional hazards regression analyses showed a significantly higher incidence of overall and death-censored graft loss in SGF group (Hazard ratio = 2.5 and 2.8, p = 0.025 and 0.035, respectively), after adjusting for background characteristics including age, sex, duration of dialysis, ABO compatibility, donor-specific antibody positivity, and medically complex donor. Regarding the risk factor for SGF, in the logistic regression analysis using the aforementioned covariates and intraoperative factors including total ischemia time, warm ischemia time, renal artery reconstruction, and right donor kidney, using 225 complete cases without missing value, only renal artery reconstruction was associated with SGF (Odds ratio = 2.8, p = 0.043).

Conclusions: CRR2 as a definition of SGF could be used to predict long-term graft outcomes. Renal artery reconstruction could be the risk factor for SGF.

Abstract# 952

The Impact of Diabetes on Young Transplant Recipients: An American Perspective

J. M. Loera, S. C. Barrett, T. S. Zhang, A. A. Awan, B. V. Murthy, R. T. Cotton, C. A. O'Mahany, N. T. Galvan, J. A. Goss, A. A. Rana, *Michael E. DeBakey Department of Surgery, Baylor College of Medicine, Houston, TX*

Purpose: Our study aims to demonstrate the impact of diabetes, types I and II, on American young adults (18-40 years old) requiring kidney transplantation.

Methods: Using the United Network for Organ Sharing database, we conducted a population cohort study which included all first-time, kidney-only transplant recipients during 2002-2019. Patients were grouped according to indication for transplant. Primary outcomes were cumulative all-cause mortality and graft failure. Graft and patient survivals at 1, 5, and 10 years were calculated via the Kaplan-Meier method. Multivariate Cox regression was used to assess for potential confounders.

Results: Of 42,473 transplant recipients, 3,418 (8.1%) had end-stage kidney disease associated with diabetes. At each time-point, cumulative mortality and graft failure were higher in diabetics compared to patients with non-diabetic causes of renal failure. Adjusted hazard ratios for all-cause mortality and graft failure in diabetics were 2.96 (95% CI 2.65-3.31; p<0.01) and 1.26 (95% CI 1.17-1.35, p<0.01), respectively.

Conclusions: This study demonstrates the vulnerability of young adult diabetic patients in the largest cohort of kidney transplant patients to date. Identifying the underlying causes of poor outcomes in this population should be a priority for future study.

Abstract# 953

Patient Survival After Living Donor Kidney Donation

M. G. Naik, K. Sakurayama, K. Budde, F. Halleck, *Medical Department, Division of Nephrology and Internal Intensive Care Medicine, Charité, Berlin, Germany*

Purpose: Living donor kidney transplantation [LDKT] is associated with best patient survival and life quality among kidney replacement therapies in case of chronic kidney disease. As risk factors for recipient [rcpt] survival are variable in previous studies, we investigated in our center.

Methods: All LDKT rcpts transplanted from 01.01.1997 to 18.03.2020 were analyzed retrospectively. Based on the relationship to their donor rcpts were grouped into "related [R]" (first-degree relatives or grandparents), "far related [FR]" (other biological relationships) and "unrelated [UR]" (not related). Endpoint of this study was patient and graft loss [pg] survival analyzed by Kaplan-Meier method and log-rank test. Independent risk factors were estimated with Cox-regression.

Results: Among 946 LDKT rcpts we identified n=504 R, n=44 FR and n=398 UR rcpts. Overall 9.1% (86) grafts failed and 10.8% (102) died. Rates of graft failure and deaths were 8.7% and 6.7% in R rcpts; 9.1% and 11.4% in FR rcpts; 9.5% and 15.8% in UR rcpts. Kaplan-Meier-analysis (figure 1) showed overall pg survival of 89.8%, 76.3% and 48.3% with median follow-up time of 5.9 years. There was a significant difference in pg survival (p<0.001) between subgroups. In the multivariate analysis (figure 2) we observed delayed graft function (HR:2.59; p<0.001) and rcpt age in years (HR:1.04; p<0.001) as independent risk factors for pg survival.

Conclusions: LDKT rcpt without biological relationship to their donors have inferior pg survival. The donor relationship as well as delayed graft function and rcpt age should be taken into account in patient evaluation. Rcpt with these characteristics should be informed about their individual risks and carefully monitored long term.

Abstract# 954

Awareness of Teratogenic Potential of Mycophenolic Acid Products and Pregnancy Outcomes in Kidney Transplant Recipients

S. Rao[1], L. Coscia[2], A. Yusuf[2], S. Constantinescu[3], M. J. Moritz[4], *[1]Nephrology, University of Virginia Heath System, Charlottesville, VA, [2]Transplant Pregnancy Registry International, Philadelphia, PA, [3]Medicine, Lewis Katz School of Medicine at Temple University, Philadelphia, PA, [4]Surgery, Lehigh Valley Health Network, Allentown, PA*

Purpose: In 2006, Transplant Pregnancy Registry International (TPRI) reported teratogenic effects of mycophenolic acid products (MPA) in pregnancies in transplant recipients. This resulted in black box warning for MPA products by the FDA for the pregnancy risk category in 10/2007, and awareness in the transplant community of pregnancy risks associated with MPA products. We aim to analyze the impact of MPA teratogenicity awareness on pregnancy outcome and patient and graft survival in kidney recipients.

Methods: The TPRI dataset was queried for pregnancies in kidney transplant recipients from 1995 to 2019. The data were collected via questionnaires, telephone interviews, and medical records review. Pregnancies were grouped into pre-awareness (1995-10/2007) and post-awareness (after 10/2007) of MPA teratogenicity.

Results: The pre-awareness group included 361 recipients, 691 pregnancies, and 718 outcomes was compared with the post-awareness group (344 recipients, 655 pregnancies, and 684 outcomes). Demographics are listed in Table 1. Among recipients taking MPA prior to pregnancy (457), there was significantly less MPA exposure during pregnancy in the post-awareness era (16% vs 44% in the pre-awareness era, p <0.001). Post-awareness era has higher planned pregnancies (75% vs 59%, p<0.001). Rejection during and after pregnancy were infrequent and similar in both groups. In both eras 74% of pregnancies resulted in live births, with high rates of prematurity (48%) and low birthweight (43%). The patient and kidney allograft survival were not independently related to the era of MPA teratogenicity awareness (Figure 1) and neither was graft loss within 2 years of delivery.

Conclusions: The increased awareness amongst the transplant community of MPA teratogenicity has resulted in higher proportion of planned pregnancies and fewer MPA exposures during pregnancy. MPA avoidance during pregnancy did not have negative impact on patient and kidney allograft survival.

Table 1: Recipient demographics, pregnancy comorbidities and outcomes based on MPA teratogenicity awareness era.

	Pre-awareness era (1995 to 10/2007)	Post-awareness era (After 10/2007)	p-value

Abstract# 955

Very Long-Term Patient and Kidney Allograft Outcomes in Kidney Transplant Recipients More Than 20 Years After Transplantation:

T. Schachtner, A. Reimann, T. Müller, *University Hospital Zurich, Zürich, Switzerland*

Purpose: Despite rapid medical advancements in the field of transplantation over the last decades, long-term kidney allograft survival only slowly improves. Especially little is known about those kidney transplant recipients (KTRs) with very long-term survival of more than 20 years.

Methods: We followed 271 KTRs with kidney allograft survival of more than 20 years on a quarterly/yearly basis in our kidney transplant outpatient clinic. KTRs were analyzed for patient and kidney allograft outcomes.

Results: Our 271 KTRs with a median age of 59 years (range 38-89) at 20 years post-transplant showed a median kidney allograft function of 51 ml/min/1.73m² (range 11-103) and median proteinuria of 236 mg/day (range 0-7260). Patient survival was 84%, 63%, and 52%, and death-censored kidney allograft survival was 85%, 76%, and 61% at 25, 30, and 35 years post-transplant, respectively. We identified 104 KTRs (38.4%) with superior kidney allograft function defined as eGFR >45 ml/min/1.73m², proteinuria <300mg/day, and eGFR slope <2ml/min/1.73m². The only independent factor associated with superior kidney allograft function at 20 years post-transplant was donor age with 25 vs. 37 years (p<0.001). Patient survival was 92%, 65%, and 52% among KTRs with superior kidney allograft function compared with 85%, 62%, and 57% among KTRs with inferior kidney allograft function at 25, 30, and 35 years, respectively (p=0.420). Death-censored kidney allograft survival was 98%, 95%, and 83% among KTRs with superior kidney allograft function compared to 78%, 59%, and 39% among KTRs with inferior kidney allograft function at 25, 30, and 35 years, respectively (p<0.001). The only independent factor associated with kidney allograft loss was the development of de novo DSA (p=0. 019).

Conclusions: While younger donor age is highly associated with superior kidney alloraft function in the very long-term, the development of de novo DSA strongly impacts kidney allograft survival. Surprisingly, ultimate patient survival did not differ between KTRs with superior and KTRs with inferior kidney allograft function at 20 years after transplantation.

Abstract# 956

Impact of Rituximab Induction Therapy on Donor-specific Anti-HLA Antibodies in Abo-compatible Kidney Transplant Recipients

T. Yagisawa[1], T. Kanzawa[1], K. Unagami[2], M. Furusawa[1], M. Inui[1], H. Ishida[2], K. Tanabe[1], *[1]Department of Urology, Tokyo Women's Medical University, Tokyo, Japan, [2]Department of Organ Transplant Medicine, Tokyo Women's Medical University, Tokyo, Japan*

Purpose: Development of de novo donor-specific anti-HLA antibodies (dnDSA) after kidney transplantation remains strongly associated with antibody-mediated rejection (AMR), which leads to poor graft outcome. Anti-CD20 antibody, rituximab (RXM) plays a role in inhibiting the B cell allo-response immunity in AMR process. This study evaluated the efficacy of RXM as an induction therapy in kidney transplant patients with or without dnDSA development. We also performed a comparative study on the graft survival rates in transplant recipients with/without rituximab RXM treatment as well as with/without de novo antibody development.

Methods: We retrospectively analyzed the data of 432 patients who underwent ABO-compatible living kidney transplantation at our institution between 2001 and 2015. Conditions of almost all patients were managed with tacrolimus and mycophenolate mofetil. Preoperative RXM induction was observed in 177 (40.9%) of the 432 patients (RXM+). Low-dose RXM 200mg was administered within 7 days before transplantation. Eighty-five (19.6%) patients (dnDSA+) were positive for dnDSA. Based on RXM induction and dnDSA production, the patients were divided into four groups as follows: RXM(+)/dnDSA(+) (n=33); RXM(+)/dnDSA(-) (n=144); RXM(-)/dnDSA(+) (n=52); and RXM(-)/dnDSA(-) (n=203). The median follow-up period was 10 years (range 7.0-14.3 years).

Results: The graft survival curve comparing each group is shown in Figure 1. Patients with dnDSA showed poor graft survival than those without dnDSA, regardless of presence/absence of RXM induction. In patients without dnDSA, RXM induction contributed to favorable graft survival. There were significant differences among the four groups (P< 0.001). The most common cause of graft loss in each group was chronic antibody-mediated rejection. The incidence rate of biopsy-proven rejection was significantly higher in the dnDSA(+) groups than that in the dnDSA(-) groups (RXM(+)/dnDSA(+) 60.6%; RXM(+)/dnDSA(-) 11.1%; RXM(-)/dnDSA(+) 55.8%; RXM(-)/dnDSA(-) 25.6%, *P*<0.001).

Conclusions: Regardless of RXM induction, the graft survival in dnDSA(-) patients was better than that in dnDSA(+) patients. RXM induction in dnDSA(+) patients was insufficient to achieve the improved graft outcome.

Kidney

Kidney Living Donor: Other

Abstract# 957

Graft Volume Changed in the First Year After Living Donor Kidney Transplantation

M. Abou Zeinab, M. Eltemamy, Y. Lin, K. Sasaki, V. Krishnamurthi, Z. Zaky, A. Wee, J. Kaouk, *Cleveland Clinic, Cleveland, OH*

Purpose: Pre-donation total kidney volume was shown to correlate with graft outcomes and long-term graft survival. However, only a few studies have studied the changes of the graft volume in the recipient, with conflicting results. We investigated variations in graft volume changes after kidney transplantation and their clinical outcomes.

Methods: Between 2012 -2019 we retrospectively reviewed 40 kidney recipients who had an abdominal Computed tomography (CT) within the first year after kidney transplantation. Recipient kidney volume (RKV) was calculated and correlated with donor kidney volume (DKV) to calculate a graft volume change percentage (GVC) (GVC= DKV/RKV x 100). Patients were divided into Group 1 (GVC less than 150%) and Group 2 (GVC more than 150%). Estimated glomerular filtration rate (eGFR) was calculated at 1-, 3- and 6-months then yearly up to 8 years post-transplantation using the CKD-EPI formula. Other clinical outcomes including rejection, BK viremia and graft survival were correlated with the GVC.

Results: The median donor age was 45 years (IQR: 37-53), median BMI was 27.3 (IQR: 23.7-29.5) and males were 42.5%. The median DKV was 171.5 cc (IQR: 150-190). Most of the allografts experienced progressive enlargement in the first year after transplant with a median RKV of 225 cc (IQR: 194-291) and a GVC of 135% (IQR: 120-165). Patients in Group 1 had a higher Median e-GFR compared to Group 2 on short and long term follow up (figure 2). Young donor kidney were more likely to be associated with a lower GVC (p=0.038).

Conclusions: Graft kidneys are expected to enlarge in the first year after transplantation. A possible explanation is compensatory hypertrophy. However other possible reasons are hyperfiltration, inflammation, and edema. Our data suggest that more than 50% enlargement of the graft in the first year is associated with a lower GFR on short and long term follow up which might reflect a pathological process rather than compensatory hypertrophy. Young donor kidneys were more likely to have less than 50% enlargement in the first year post-transplant.

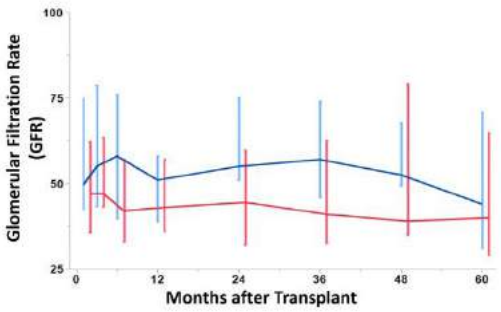

Figure 2. Median glomerular filtration rate. Group 1 (blue) have better GFR overtime compared to Group 2 (red).

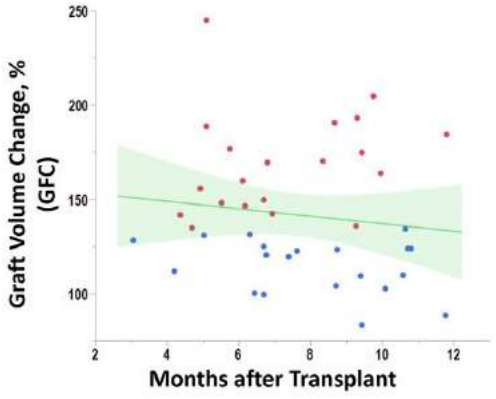

Figure 1: Graft volume changes. Group 1 are (Blue) are separated from Group 2 (Red)

Abstract# 958

Modifiable Barriers in Decision Making Around Living Donor Kidney Transplantation - A Rapid Scoping Review to Guide (DEAL-KD) Study

A. Ahmed[1], A. Winterbottom[1], S. Ahmed[2], J. Stoves[3], S. Daga[1], *[1]Leeds Teaching Hospitals Trust, Leeds, United Kingdom, [2]Division of Psychological and social Medicine, University of Leeds, Leeds, United Kingdom, [3]Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom*

Purpose: Living donor kidney transplantation (LDKT) is the optimal modality of renal replacement therapy for patients with advanced renal disease; associated with superior recipient and graft survival. LDKT offers better perceived quality of life and self-reported health status versus dialysis. The decision making can be complex; healthcare professionals convey information to patients but rely on the recipient to encourage potential donors to engage. LDKT occurs less frequently in Black and Minority Ethnic (BAME) groups compared to Caucasians. This rapid scoping literature review aims to identify modifiable barriers in the decision making to pursue LDKT with a focus on BAME populations

Methods: 208 articles were identified from Pubmed and Medline using keywords; barriers, decision making, living donor, kidney transplantation. Studies focusing on donors, paediatric recipients and abstracts for conference purposes only, were excluded.

Results: 25 studies were included; USA (15), Netherlands (3), Canada (3), New Zealand (3), UK (1). 18 studies, based in the USA (13), Netherlands (3), New Zealand (2) included BAME groups; African Americans (8), far East Asian (1) ,Hispanics (3) , and mixed other (6). South Asians were represented in one study, as 6% of the study sample. Key barriers identified were; 1) Lack of knowledge and insight into LDKT 2) Higher risk perception 3) Fear of financial burden on donors 4) Guilt for requiring a kidney and causing potential harm 5) Religious and cultural reservations.

Conclusions: This literature review provides a global perspective on modifiable barriers to decision making in pursuing LDKT. This review will inform The Decision Around Living Kidney Donation (DEAL-KD) study (ref: KRY 19-127) to create a patient decision aid to address these perceptions and facilitate engagement with particular focus on South Asian groups the second largest ethnic group in the UK. Further exploration of stakeholder views will enable the development of a culturally sensitive, evidence-based resource

Seasonal and Income-related Factors in Live Kidney Donation in the United States from 1995 to 2019

F. Al Ammary[1], A. Arking[2], G. Kaddu[2], J. Garonzik Wang[2], A. B. Massie[2], D. Segev[2], A. Muzaale[2], *[1]Medicine, Johns Hopkins University, Baltimore, MD, [2]Surgery, Johns Hopkins University, Baltimore, MD*

Purpose: For nearly two decades, the annual number of US live kidney donors has been characterized by striking and worrying patterns of general decline that differ by donor-recipient relationship. But thus far no factor has been identified to explain, and reverse, these patterns. We assessed seasonal and income-related factors to refine our understanding of trends in live kidney donation.

Methods: We studied SRTR data on 141,965 live kidney donors in the US from 1995-2019. We examined within-year seasonal variation and between-year trends using Poisson regression, stratified by donor-recipient biological relationship and estimated household income tertiles.

Results: Within any given year, kidney donation was highest in the summer months for related and unrelated donors across all income groups. From year to year, the number of related donors across all income groups increased from 1995-2004 and then decreased from 2005-2019 in any given season [Figure 1]. The number of unrelated donors across all income groups increased from 1995-2004 in any given season, but thereafter the trends varied by income tertile from 2005-2019: increased for the high income tertile across all seasons, increased for middle income tertile only in summer months but decreased in winter months; and decreased for low income tertile in any given season [Figure 2].

Conclusions: Overcoming financial barriers associated with non-summer donations can potentially translate into timely, life-saving live kidney donation.

Abstract# 960

Decreased Pca and Regional Anesthesia Requirements Following Robotic Donor Nephrectomy

J. C. Alonso-Escalante, L. Machado, K. R. Tabar, R. P. Tindall, N. Thai, T. Uemura, *Surgery, Allegheny General Hospital, Pittsburgh, PA*

Purpose: Robotic donor nephrectomy is increasingly popular, however, studies have not yet shown a clear benefit. The main aim of this study is to evaluate whether robotic donor nephrectomy has any impact on postoperative pain control, patient-controlled analgesia (PCA), epidural or peripheral block use. Additionally, the rate of donor chyle leak and recipient slow graft function (24hr creatinine reduction ratio <40%) were compared.

Methods: Patients who have undergone a donor nephrectomy between June 2017 and March 2020 were studied and split in two groups: robotic donor nephrectomy (n=34) and laparoscopic donor nephrectomy (n=50). Patients were asked to rate their pain intensity in a scale of 1-10, and the maximum pain score obtained in the first 24 hours was compared using a Mann Whitney test. The number of patients who required a PCA, epidural or peripheral block in the first 24 hours was compared using Fisher's exact test. The rate of chyle leak and slow graft function (SGF) was analyzed using Fisher's exact test. Slow graft function was defined as less than 40% creatinine reduction ratio within 24 hours.

Results: No statistically significant difference was obtained with regards to post-operative pain control. Fewer patients in the robotic nephrectomy group required a PCA, epidural or peripheral block (Table 1). None of the robotic donors developed a chyle leak, as opposed to two laparoscopic donors. Slow graft function was only encountered in the laparoscopic donor group. None of these findings were significant (Table 2).

Conclusions: This single-center retrospective study shows that robotic donor nephrectomy results in a decreased use of PCA and regional anesthesia blocks, which will help expedite donation as operative times continue to improve. Furthermore, the absence of chyle leaks and SGF in the robotic donor group is a strong incentive to continue implementing this new technology.

Table 1: Pain Score, PCA and Regional Anesthesia Requirements			
	Robotic	Laparoscopic	p value
Maximum Pain Score (1-10)	7	6	0.09
PCA	38%	92%	<0.01
Epidural or Peripheral Block	0%	80%	<0.01

Table 2: Clinically Significant Chyle Leak and Slow Graft Function			
	Robotic	Laparoscopic	p value
Chyle Leak	0	2	0.51
SGF	0	1	0.99

Abstract# 961

Kidney Transplantation in Patients with Hereditary Kidney Diseases

Y. Caliskan[1], N. Garayeva[2], A. B. Dirim[2], S. Safak[2], S. Mirioglu[2], H. Yazici[2], A. Yildiz[3], O. A. Oto[2], E. Demir[2], Y. Ozluk[4], A. Turkmen[2], K. Lentine[1], *[1]Saint Louis University, Saint Louis, MO, [2]Division of Nephrology, Istanbul University, Istanbul, Turkey, [3]Division of Nephrology, Uludag University, Bursa, Turkey, [4]Department of Pathology, Istanbul University, Istanbul, Turkey*

Purpose: Genetic testing is poised to play a larger role in the evaluation and management of both kidney transplant (KTx) recipients and donors. We characterized genetic variants and examined KTx outcomes among recipients with hereditary kidney diseases.

Methods: A total of 96 prevalent KTx recipients with a blood relative diagnosed with a kidney disease by kidney biopsy, imaging or genetic testing were evaluated. Genetic sequencing, either whole exome sequencing (WES) (n=38) or a targeted gene panel (n=58), was performed. Graft loss risk was compared by donor type using multivariate Cox regression. Living donors were also followed for renal outcomes.

Results: The genetically sequenced cohort comprised 58% men with mean age at KTx of 33±11; 70% were living related (LR), 8% living unrelated (LUR), and 22% deceased donor (DD) KTx recipients. We identified a diagnostic variant in 86% KTx recipients with hereditary kidney diseases including familial Mediterranean fever [43 of 43 recipients (100%)], FSGS (19/22, 86%), CAKUT (1/8, 12.5%), atypical hemolytic uremic syndrome (6/6, 100%), Alport syndrome (5/5, 100%), Fabry disease (4/4, 100%), C3 Glomerulopathy (4/4, 100%) and nephronophthisis (1/1, 100%). When grouped according to donor type, LUR KTx recipients were significantly older (48±7 yrs) than the LR (32±11 yrs) and DD (33±10 yrs) KTx recipients (p<0.001). Number of HLA mismatch was also higher in LUR KTx (4.1±0.8) than LR (2.8±1.1) and DD (3.0±0.9) KTx recipients (p<0.003). All groups were similar regarding gender, primary disease, post-KTx follow-up time. During a median follow up time of 9 years (IQR, 5-12), the rate of graft loss was significantly higher in DD KTx recipients [9/21 (43%)] compared to LUR [2/8 (25%)] and LR [11/67 (16%)] KTx groups (p=0.04). In Cox regression including adjustment for age and number HLA mismatches, DD KTx was significantly associated with 2.9-times increased risk of allograft loss (adjusted hazard ratio, $_{1.20}2.93_{7.12}$) (p=0.018). Of 67 LR donors, only one (1.5%) developed nephrotic range proteinuria and biopsy confirmed FSGS during 9 years of follow-up. None of the LR donors required renal replacement treatment.

Conclusions: Living donor KTx is the best option for ESKD patients with hereditary kidney diseases. Although the risk is low, the possible occurrence of the same disease in the related living donor can happen.

Figure 1. Cox proportional hazards regression curves of groups adjusted for potential confounding factors including age and number HLA mismatch (p=0.018).

Abstract# 962

Effects of Transverse Abdominis Plane Blocks on Opioid Requirements Post Kidney Donation

R. Caputo, O. Witkowsky, A. Rajab, *The Ohio State University Wexner Medical Center, Columbus, OH*

Purpose: There is lacking data regarding the use of transverse abdominis plane (TAP) blocks to reduce post-operative opioid requirements in kidney donors (KD). TAP blocks may serve as an effective adjunct in multimodal pain management to reduce the need for opioid analgesia. The purpose of this study was to review the opioid requirements of KD who did and did not receive a TAP block.

Methods: This was a single-center, retrospective study of all patients who underwent nephrectomy for living kidney donation between September 2018 and September 2020. The primary outcome was the total milligrams of oral morphine equivalents (OMEs) used during the postoperative period to discharge. Secondary outcomes included total OMEs of non-patient controlled analgesia (PCA) IV opioids used and total OMEs of oral opioids, length of stay (LOS), 30-day readmission rates, and pain scores.

Results: A total of 158 KD were included. There were 50 KD in the non-TAP group and 108 KD in the TAP group. Overall, the groups had similar characteristics (Table 1). The median total OME use was 235 (126-328) milligrams in the non-TAP group versus 207 (116-258) milligrams in the TAP group (p=0.064). Excluding PCA use, IV OME use was significantly lower in the TAP group [19 (8-38) vs 39(20-50) milligrams, p<0.001]. Oral OME use was similar between the non-TAP and TAP groups [75 (45-105) vs 75 (44-105), p=0.66]. Combined IV plus oral OME use was not significantly different between the non-TAP and TAP groups [118 (75-171) vs 104 (56-133), p=0.06]. Average LOS was 3.2±0.6 days for both groups. There were 3 (6%) readmissions within 30 days of discharge in the non-TAP group, two of which were for ileus and small bowel obstruction, versus 1 (<1%) readmission in the TAP group. None of the readmissions were related to pain control. The average pain score between the non-TAP and TAP groups were also similar (4.8±1.3 vs 4.8±1.2).

Conclusions: Use of TAP blocks resulted in an overall decrease in post-operative opioid requirements among KD. TAP block use significantly reduced the amount of IV OMEs used.

Table 1

	Non-TAP group (n=50)	TAP group (n=108)	P-value
Age (years), mean ± SD	45±12	43±12	
Male, %	24	37

Abstract# 963

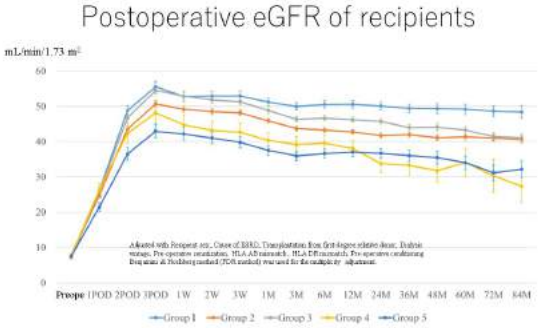
The Impact of Donor Age and Donor-Recipient Age Difference on Living Donor Kidney Transplantation

T. Hiramitsu[1], T. Tomosugi[2], K. Futamura[2], M. Okada[2], N. Goto[2], T. Ichimori[2], S. Narumi[2], Y. Watarai[2], *[1]Nagoya Daini Red Cross Hospital, Myokencho Showaku, Japan, [2]Nagoya Daini Red Cross Hospital, Nagoya, Japan*

Purpose: The impact of donor age and donor-recipient age difference on living donor kidney transplantation have not been investigated simultaneously.

Methods: A total 805 adult living donor kidney transplantation between January 2008 and December 2018 including donor age > 30 years old and donor-recipient age difference -10 - +10 years or +20 - +40 years was investigated. Recipients were stratified into 5 groups according to the donor age and donor-recipient age difference: Group 1 (120 recipients), donor age 30 - 49 years old and donor-recipient age difference-10 - +10 years; Group 2 (338 recipients), donor age 50 - 69 years old and donor-recipient age difference-10 - +10 years; Group 3 (240 recipients), donor age 50 - 69 years old and donor-recipient age difference +20 - +40 years; Group 4 (28 recipients), donor age 70 - 89 years old and donor-recipient age difference -10 - +10 years; Group 5 (79 recipients), donor age 70 - 89 years old and donor-recipient age difference +20 - +40 years. Recipient postoperative eGFR was compared with linear mixed model analysis. Benjamini & Hochberg method was used for multiple comparisons. Risk of graft loss was analyzed with Cox regression hazard model.

Results: In the recipient and donor characteristics, significant differences were identified in donor sex, recipient sex, cause of end stage renal disease, recipient body mass index, relationship between donor and recipient, dialysis vintage, preoperative sensitization, HLA AB mismatch, HLA DR mismatch, preoperative conditioning including retuximab and plasmapharesis, and calcineurin inhibitor at transplant. Postoperative eGFR of recipients were adjusted for these factors. The postoperative eGFR showed difference among groups.



eGFR of Group 4 and 5 were the lowest and eGFR of Group 1 was the highest among groups. Univariate analysis of Cox regression hazard model showed Group 4, recipient sex, preoperative sensitization including transplantation, pregnancy, and transfusion were the significant risk for the graft loss (P = 0.001, P = 0.016, P = 0.020, respectively). Multivariate analysis showed Group 4 and recipient sex were the significant risk for graft loss (P < 0.001, hazard ratio 19.07, 95% confidence interval 4.877 - 74.558, P = 0.045, hazard ratio 2.74 95% confidence interval 1.022 - 7.346).

Conclusions: Postoperative eGFR of recipients correlated with donor age. Donor age 70 - 89 years old and donor-recipient age difference -10 - +10 years was the significant risk for the graft loss.

Abstract# 964

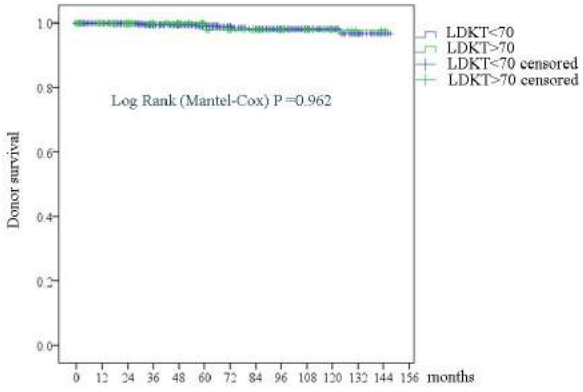
The Impact of Living Donors Aged 70 and Older on Living Donor Kidney Transplantation

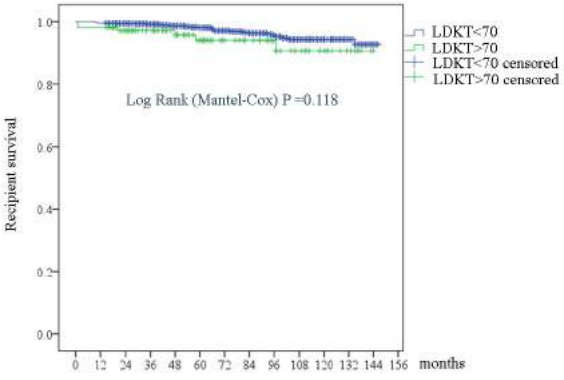
T. Hiramitsu, T. Tomosugi, K. Futamura, M. Okada, N. Goto, T. Ichimori, S. Narumi, Y. Watarai, *Nagoya Daini Red Cross Hospital, Nagoya Aichi, Japan*

Purpose: Due to the discrepancy between the number of patients on the waiting list and oragn supply, living donor kidney transplantation is more required. The number of living donors aged 70 and older is gradually increasing. We investigated the safety of living donor kidney transplantation from living donors aged 70 and older.

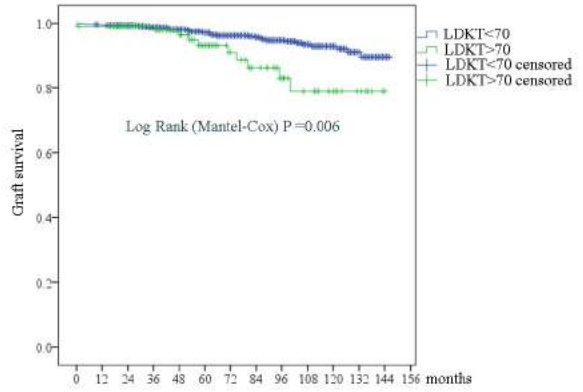
Methods: Between January 2008 and December 2018, a total 978 adult living donor kidney transplantations (LDKTs) was performed. A total of 879 LDKTs was included in this study. LDKT was stratified into 2 groups; 769 LDKTs from donors aged less than 70 (LDKT<70) and 110 LDKTs from donors aged 70 and older (LDKT>70). Operative results of donors and recipients, postoperative eGFR of donors and recipients, mortality rate of donors and recipients, graft survival rates, and incidence of end stage renal disease in donors were compared between LDKT<70 and LDKT>70.

Results: Operative results of donors including warm ischemic time, operation time, blood loss, and incidence of perioperative and postoperative adverse events showed no significant difference. Operative results of recipients including cold ischemic time and incidence of perioperative and postoperative adverse events showed no significant difference. eGFR of donors and recipients in LDKT>70 were significantly lower than those of LDKT<70. The mortality rate of donors and recipients showed no significant difference.





The graft survival rates of LDKT>70 showed significantly lower than that of LDKT<70 (P = 0.006).



End stage renal disease of donors was not identified in both LDKT<70 and LDKT>70.

Conclusions: LDKT from donors aged 70 and older was demonstrated to be a safe operation although graft loss rate in donors aged 70 and older was significantly higher than that in donors aged less than 70.

Abstract# 965

Identifying Health-System Level Barriers and Facilitators to Living Donor Kidney Transplantation: A Comparative Case Study

A. Horton[1], M. Fortin[2], P. Nugus[3], D. Landsberg[4], M. Paquet[2], M. Cantarovich[1], S. Sandal[1], *[1]Nephrology, McGill University Health Centre, Montreal, QC, Canada, [2]Nephrology, Centre Hospitalier de l'Université de Montréal, Montreal, QC, Canada, [3]Family Medicine, McGill University, Montreal, QC, Canada, [4]Nephrology, University of British Columbia, Vancouver, BC, Canada*

Purpose: Despite the well-known advantages of living donor kidney transplantation (LDKT), rates at many centers have stagnated or declined. In Canada, there are large interprovincial variations in LDKT rates, the reasons for which are not well understood. The objective of this study is to identify health system-level barriers and facilitators to LDKT by investigating and comparing health systems.

Methods: This research takes the form of a comparative case study, which entails analyzing similarities, differences, and patterns across multiple cases. Each province presents a case. Thus, we are comparing the health systems in three provinces, where 50-60%; 30-40%; <15% of kidney transplants done annually are from living donors. Data collection involves document analysis; semi-structured interviews; participant observation. Our qualitative methodology reflects the need to understand health systems as an integrated whole - across macro, meso and micro levels - by investigating the relationships between its agents (Figure 1). Data are being analyzed using framework analysis.

Results: We commenced research in the province with the highest rates of LDKT. Thus far we have conducted 15 interviews with personnel from various organizations involved in co-ordinating LDKT, whilst initiating document analysis of organizational guidelines, policies and resources. Preliminary themes from this province reveal: 1) Efforts to increase LDKT are not only focused on micro levels; 2) Strong links exist between multiple levels of practice - macro, meso and micro - that are involved in facilitating LDKT; 3) Professional networks and working groups span the core to periphery of renal practices in the province; 4) These groups have developed educational initiatives and standardized resources related to LDKT; 5) These efforts facilitate buy-in to LDKT as a treatment option across the province.

Conclusions: Preliminary results suggest that in order to increase rates of LDKT in lower-performing provinces, interventions must target the dynamic relationships between different elements of a system. This contradicts current efforts that primarily target barriers on the micro-level (i.e. the patient). Thus, efforts to increase LDKT, must target multiple levels of practice in order improve access and capacity for LDKT.

Abstract# 966

The Evaluation of Living-Related Kidney Transplantation Donors in Autosomal-Dominant Polycystic Kidney Disease

T. Kikuchi[1], K. Unagami[2], Y. Kobari[3], T. Yagisawa[3], T. Kanzawa[3], K. Omoto[3], A. Uemura[1], H. Ishida[2], K. Tanabe[3], *[1]Urology, Kindai University Hospital, Osaka, Japan, [2]Organ transplant medicine, Tokyo Women's Medical University Hospital, Tokyo, Japan, [3]Urology, Tokyo Women's Medical University Hospital, Tokyo, Japan*

Purpose: Autosomal-dominant polycystic kidney disease (ADPKD) is a progressive hereditary disease caused primarily by gene mutations, leading to multiple kidney cyst occurrence, kidney function deterioration, and end-stage renal disease (ESRD). The gene mutations have been identified as PKD1 and PKD2, however, genetic testing is not commonly available; therefore, diagnosis of ADPKD, including work-up for kidney transplantation (KTx) recipients, is usually done through history taking and imaging tests such as computed tomography and/or ultrasound examination. In KTx, blood-relative donors who have the PKD1 and PKD2 gene mutation have an increased risk of developing ADPKD with worsening renal function after nephrectomy. However, these donors' pre-KTx work-up also involves imaging, renal function tests, etc., and does not include genetic testing. We retrospectively investigated the post-operative outcomes of living KTx donors whose recipients' etiology of ESRD were ADPKD.

Methods: We evaluated a total of 90 patients who received KTx from living donors at the Department of Urology of Tokyo Women's Medical University between 2000 and 2020. For the donor type, blood relative groups in 37 cases and non-blood relative (which represents, spouses, fathers, mothers, brothers, sisters, and sons-in-law) in 53 cases were enrolled in this study.

Results: There were no significant differences in renal function between the two groups (graft failure: two cases (5.4%) in the blood relative group, and three cases (5.6%) in non-blood relative group). New occurrence and/or enlargement of renal cysts in allograft for recipients from blood relative donors have been observed in four cases without renal function deterioration. For blood donors, there was no occurrence of renal cysts or deterioration of renal function (eGFR: 45.1±7.6ml/min/1.73 m^2).

Conclusions: For blood-relative KTx donors whose recipients have ADPKD, there is stable renal function with no occurrence of renal cysts. Therefore, the outcome of this study indicates that KTx can be performed with minimal risk of developing ADPKD after KTx in living-relative donors.

Table Patient characteristics

Abstract# 967

Developing a Robot-assisted Donor Nephrectomy Program in a High Volume Laparoscopic Living Donor Nephrectomy Program

S. S. Lee, N. Vachharajani, M. Pfeiffer, S. Matson, M. Scherer, M. Doyle, J. Wellen, Y. Lin, T. Rice, J. Yu, A. Khan, *Abdominal Transplant Surgery, Washington University at St. Louis, St Louis, MO*

Purpose: Three dimensional visualization, improved dexterity and fine instrument control make robotic surgery an attractive option for further improving the safety profile of laparoscopic living donor nephrectomy (LDN). This is a single center review of the initial experience of a high volume kidney transplant program in transitioning from laparoscopic to robotic donor nephrectomy (RDN).

Methods: Retrospective review of prospectively maintained living donor nephrectomy database at Washington University in St Louis. RDN was implemented in 2020 after 3 months of program building. Donor and recipient data for the first 30 RDNs was reviewed and compared with the last 30 LDNs to assess learning curve and safety profile.

Results: The mean age of patients undergoing RDN was 47 years, the majority were female (72%) and the average BMI was 27. Ninety-three percent had left sided nephrectomy and one-third had more than one artery or vein. The total operative time (TOT) was 194 minutes with console time of 128 minutes. There were no conversions to laparoscopic or open surgery. Estimated blood loss was 62 ccs, and median length of stay (LOS) was 2 days. Significant complication (Clavien-Dindo III-IV) was seen in one patient (pneumothorax). There were no complications in recipients related to donor surgery technique. There was no difference between

the RDN and LDN studied variables except for TOT and the warm ischemia time (WIT), defined as cross clamp to on ice time, which were significantly longer for RDN groups (194 mins vs. 136 mins and 5 mins vs. 2 mins, respectively). All kidneys were transplanted successfully with no difference in delayed function and graft survival rates between the two groups.

Conclusions: RDN is a viable alternate to LDN and can be safely implemented after careful planning and team building with comparable donor and recipient outcomes. Improved visualization and ergonomic ease offer potential advantages over LDN.

Donor Variables			
	RADN	LDN	p-value
WIT (min)	5 (+/- 2)	2 (+/- 1)	<0.0001

Abstract# 968

Alterations in Mineral Metabolism of Living Kidney Donors: Prospective Observational Study

H. Lee[1], E. Ko[1], H. Cho[2], C. Yang[1], B. Chung[1], *[1]Division of Nephrology, Department of Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea, Republic of, [2]Department of Urology, Seoul St. Mary's Hospital, Seoul, Korea, Republic of*

Purpose: The aim of this study is to investigate whether reduction in glomerular filtration rate (GFR) after kidney donation causes mineral metabolism alterations, and also investigate what factors associated with mineral metabolism adaptation.

Methods: 144 living kidney donors (LKDs) in Seoul St. Mary's hospital between May 2016 and September 2018 were enrolled, prospectively. Laboratory evaluation, 24-hour urine collection and Technetium-99m diethylene-triamine-pentaacetate scan were performed in two subsequent time points; pre-donation and 6-month after donation. LKDs were divided into 2 groups according to the difference of fractional excretion of phosphate (FEPi).

Results: 6-month after uni-nephrectomy, estimated GFR (eGFR) declined (100.76 to 66.89 ml/min/1.73m^2) significantly ($p<0.001$). After donation, serum phosphorus decreased ($p<0.001$), whereas FEPi (13.34 to 20.23 %, $p<0.001$) and serum iPTH (38.70 to 52.20 pg/ml, $p<0.001$) were increased. In subgroup analysis, semi-log FGF-23 tended to increase after donation (85.20 to 106.71 pg/ml, $p=0.092$). Percentage change in eGFR was significantly higher in high delta FEPi group ($p=0.043$). In multivariable logistic regression, the odds ratio of percentage change in eGFR was 1.076 ($p=0.005$).

Conclusions: After uni-nephrectomy, LKDs develop secondary hyperparathyroidism related to a decreased serum phosphorus, increased FEPi. Moreover, the greater the reduction of GFR occurs, the greater adaptation of mineral metabolism follows.

Abstract# 969

Kidney Transplant Associated Allergy Transfer After Living Donation

K. López-Vega, S. Davis, *Division of Renal Diseases and Hypertension, Anschutz Medical Campus, University of Colorado, Aurora, CO*

Purpose: Donor to recipient IgE-mediated food allergy transfer has been described in non-kidney solid organ transplant. Here, we report a novel case of an adult post-transplant kidney allergy transfer resulting in anaphylaxis.

Methods: A 56-year-old man with ESRD secondary to PKD underwent a living donor transplant with thymoglobulin induction and maintenance tacrolimus, mycophenolate, and prednisone. Four weeks after transplant, he developed a de novo anaphylactic reaction, presenting with swollen throat and lips and hives after ingesting a collagen bar containing cashews. These symptoms progressed to hypotension, generalized rash, shortness of breath, and loss of consciousness requiring emergency treatment with epinephrine. The patient had no prior history of food allergy. Evaluation of the donor's medical record revealed a history of allergies to pine nuts, hazelnuts, macadamia, and cashews. Further testing revealed positive skin testing for cashews and pistachio. In contrast, skin testing was negative for walnut, pecan, and brazil nut. Serum specific IgE testing was negative to walnut, pecan, hazelnut, pine nut, and macadamia nut. The oral challenge was negative for macadamia nut, pecan, and walnut. The patient was instructed to avoid ingestion of cashews and pistachio and received education on the use of Epi-pen in case of incidental exposures.

Results: This is the first case of allergy transfer on an adult patient after receiving a kidney transplant. The other case described after a kidney transplant was on a 7-year-old patient. Although increased risk for atopic diseases occurs after transplantation, donor to recipient acquired food allergies have been described mostly on liver, lung, and combined pancreas-kidney transplants. Some of the possible mechanisms for posttransplant acquired allergy are binding of passively transferred IgE to recipient mastocytes and transfer of IgG-memory B cells, IgE-producing B cells, clone specific T cells, and tissue-resident mastocytes. Although it has been speculated that the kidneys contain a small amount of memory B cells explaining the low risk for posttransplant acquired allergies, this case suggests allergy transfer after kidney transplant is possible.

Conclusions: Fatal anaphylactic reactions in non-kidney solid organ transplants have led to the development of protocols to identify patients at risk for severe donor-derived food allergies. Review of food allergies among living kidney donors prior to transplant may be a simple and effective tool to prevent this rare but life-threatening complication in kidney transplant recipients, as well.

Abstract# 970

Which Living Kidney Donors Arrive to the Donation Process Informed About Surgery?

L. Malinzak, A. Segal, R. Prashar, M. Jesse, *Henry Ford Hospital, Detroit, MI*

Purpose: To evaluate perceived knowledge about surgery in potential living kidney donors embarking on the donation process.

Methods: Potential living kidney donors were surveyed about their level of familiarity with donor surgery. Candidates used the BREEZE TRANSPLANT™ program which allows submission of basic information to help determine potential candidacy for donation. 75 applications were reviewed. 55 applications were considered complete and were evaluated. The survey included questions about knowledge of robotic surgery, laparoscopic surgery, or kidney paired donation (KPD). Response options about KPD included: None, general idea or has learned about KPD. Response options regarding surgery were: Not familiar, somewhat familiar or very familiar. Those who answered somewhat familiar or very familiar were grouped together as being knowledgeable about surgery. Free hand answers were also accepted.

Results: Of the 55 patients surveyed, 16 (29%) reported they were knowledgeable about surgical options: 10 (18%) reported being knowledgeable about both robotic and laparoscopic surgery, 4 (7%) reported they were only knowledgeable about laparoscopic surgery, and 2 (4%) reported they were only knowledgeable about robotic surgery.

There were no significant differences between a patient's perceived knowledge of robotic surgery and their age, educational level, referral sources (tx candidate or friend/family of candidate compared to all others), knowledge of KPD or median income. Those who reported some level of knowledge of laparoscopic surgery (vs no knowledge) were also more likely to report some knowledge of robotic surgery($p<0.001$). Those who reported they were highly motivated (vs unsure or interested but wanted more information) were significantly more likely to report some knowledge of robotic surgery ($p<0.024$).

There were no significant differences between a patient's knowledge of laparoscopic surgery and motivation, education level, referral source, and KPD knowledge.

Of the 12 patients (22%) who attempted to free text their knowledge of robotic and laparoscopic surgery, 6 patients (10%) indicated they had some knowledge of both laparoscopic and robotic surgery, 5 patients (9%) stated they had no knowledge and 1 patient (2%) felt knowledgeable about only laparoscopic surgery

Conclusions: Highly motivated donors reported being more knowledgeable about robotic surgery prior to starting the living kidney donation process. It may be the case that highly motivated donors are self-selecting to centers that offer robotic surgery. Or being highly motivated, the donors have already begun seeking education.

Abstract# 971

Multimodal Analgesia Reduces Length of Stay in Living Kidney Donors

K. Marti[1], D. O'Sullivan[2], X. Ye[3], C. Rochon[3], H. Kutzler[3], *[1]Pharmacy, Hartford Hospital, Hartford, CT, [2]Research Administration, Hartford Hospital, Hartford, CT, [3]Transplant, Hartford Hospital, Hartford, CT*

Purpose: This study evaluated the outcomes between living kidney donors who received a multimodal analgesic regimen compared to a historical cohort that did not.

Methods: Hartford Hospital implemented a multimodal analgesic regimen for living kidney donors in March 2019. This regimen consists of pharmacist-led pre-procedure pain management education, a transverse abdominis plane (TAP) block with bupivacaine and dexamethasone, scheduled acetaminophen and gabapentin, and as-needed opioids. This was a single-center retrospective chart review of patients who underwent laparoscopic living donor nephrectomy from 8/16/2016-7/1/2020. Patients who received the multimodal regimen comprised the multimodal (MM) group, and those who did not comprised the historical group.

Results: The baseline characteristics are described in Table 1. 68 patients comprised the historical group and 44 comprised the MM group. The MM group had a significantly shorter length of stay (LOS) (days, mean±SD: 1.8±0.7 vs 2.6±0.8; p<0.001). More patients were discharged on postoperative day (POD) 1 in the MM group (38.6% vs 1.5%; p<0.001). The total morphine milligram equivalents (MME) donors received while inpatient was significantly less in the MM group vs the historical group on POD 0-2 (Figure 1). The outpatient MME prescribed through POD 60 was also significantly less in the MM group (median [IQR]; 180 [150-188] vs 225 [150-300]; p<0.001). The mean patient-reported pain score (PRPS) was significantly lower in the MM group vs the historical group on POD 0, 1, and 2 (Figure 1). The maximum PRPS was significantly lower on POD 0 in the MM group (mean±SD: 7±2 vs 8±1; p=0.02). There was no significant difference in renal function prior to donation through POD 180. There were no significant differences in readmission (4.5% vs 4.4%; p=0.97), surgical site infection (2.3% vs 4.4%; p=0.55), or postoperative ileus (0% vs 7.4%; p=0.07), between the MM and historic groups, respectively.

Conclusions: In conclusion, this multimodal analgesic regimen resulted in a significantly shorter LOS, significantly lower PRPS, and significantly lower opioid requirements following living kidney donation.

Table 1: Baseline characteristics	Multimodal (n = 44)	Historical (n = 68)	P value

Abstract# 972

Preempting Misconceptions: An Educational Initiative for Preemptive Kidney Transplant Candidates

T. Menser[1], M. Hobeika[2], H. Ibrahim[2], A. Khan[1], B. Cruz[2], J. Sharp[2], A. Gaber[2], *[1]Houston Methodist Research Institute, Houston, TX, [2]Houston Methodist Hospital, Houston, TX*

Purpose: reemptive living donor kidney transplantation (pLDKT) offers many advantages for patients with advanced chronic kidney disease. However, pLDKT represents less than 1 out of 6 U.S. kidney transplants, with documented racial, ethnic, and gender disparities in utilization.

Methods: *Transplant: A Family Journey* is a two-hour educational session for preemptive kidney transplant candidates, family, and friends held prior to initial transplant evaluation. A knowledge pretest was administered based on a validated end-stage renal disease treatment knowledge assessment converted to true-false format. The course information is presented by a clinician on treatment options, and then a prior living donor/recipient share their stories of pLDKT. Participants are encouraged to ask questions throughout. Study team members observed these courses and took verbatim notes of participants' mid-session questions and later conducted qualitative thematic analysis on the question content.

Results: Seven educational sessions were performed between December 2019 and March 2020 involving 56 patients and 92 family/friends at a neutral, non-hospital affiliated site. Pretest questions most often answered incorrectly included the topics of recovery time required for living donors, length of function for transplanted kidneys, average amount of time spent on the waitlist for a deceased donor kidney, Medicare coverage time post-transplant, and lifestyle changes required after living donation. Non-white patients more often answered questions on these topics incorrectly: "Surgery will not affect the donor's ability to have children" and "Living donors need to take medication after they donate." Additionally, 54% of male patients had misconceptions about insurance coverage compared to 30% of females. There were a total of 126 participant-generated questions asked mid-session, classified into six main categories (Figure 1) that can be used to guide future educational interventions.

Conclusions: Pre-evaluation education directed towards pLDKT candidates and their family/friends elucidates patterns of misunderstanding which may be used to reduce disparities in access to pLDKT.

Abstract# 973

Clinical Outcomes of Living Kidney Transplantation from Elderly Spousal Donors

Y. Miyauchi, T. Noda, N. Miura, T. Kikugawa, T. Saika, *Ehime University, Toon, Japan*

Purpose: In Japan, the spousal kidney transplantation accounts for approximately 40% out of whole living kidney transplantation. In addition, about half of whole living donors are over 60 years old. Transplantations from elderly donors have been shown to display impaired long-term graft outcomes. We aimed to examine whether spousal kidney transplantation of elderly donors is clinically acceptable.
Methods: We included 98 recipients with living donor kidney transplantation between 2006 and 2020 in this study. We compared to examine 27 cases of living kidney transplantation from elderly spousal donors aged 60 years or older (group A) and 34 cases of living kidney transplantation from elderly related donors aged 60 years or older (group B). Twelve donors (44.4%) in Group A were male, that is, their husbands, and 31 donors (91.2%) in group B were parents of recipients.
Results: The median donors' age of group B was significantly older than that group A (64 years old vs 72 years old, $p<0.05$), On the other hands, the median recipients' age was significantly older in group A than that in group B (66 years old vs 45 years old, $p<0.001$). Blood type incompatibility was significantly higher in group A than in group B (44.4% vs 20.6%; $p<0.05$). Seven recipients (25.9%) in group A and 6 recipients (17.6%) in group B had preformed donor specific antibodies (DSAs), but there was no significant difference. Four recipients (14.8%) in group A had de novo DSAs after transplantation, which was significantly higher than that in group B (0%; $p<0.05$). Human leukocyte antigen incompatibility is significantly higher degree in group A ($p<0.001$). Rituximab was used significantly more frequently in Group A than in Group B because of, for example, blood type incompatibility, presence of DSAs, and pregnancy history (96.3% vs 52.9%; $p<0.001$). The volume of donated kidney was measured by CT, but there was no significant difference between the two groups. Graft function tended to be superior in group A, but there was no significant difference in the long term, and there was no significant difference in rejection rate or graft survival rate.
Conclusions: Using suitable immunosuppressive regimen, the outcomes of elderly spousal transplantation are also satisfactory.

Abstract# 974

A Dynamic Markov Model to Assess the Cost-Effectiveness of the Kidney Team at Home Intervention in the Netherlands

S. Redeker[1], S. Ismail[1], H. van Eeren[1], E. K. Massey[2], W. Weimar[2], M. Oppe[3], J. van Busschbach[1], *[1]Psychiatry, Erasmus MC, Rotterdam, Netherlands, [2]Internal Medicine, Erasmus MC, Rotterdam, Netherlands, [3]Axentiva Solutions S.L., Tacoronte, Spain*

Purpose: The Kidney Team at Home program is an educational intervention aimed at patients with chronic kidney disease to assist them in their choice for kidney replacement therapy. Previous studies have shown that the intervention results in an increase in knowledge and communication on kidney replacement therapy, and eventually in an increase in the number of living donor kidney transplantations. The present study assesses the cost-effectiveness of the intervention compared to standard care.
Methods: A dynamic probabilistic Markov model was used to estimate the monetary and health benefits of the intervention in the Netherlands over 10 years. Data on costs and health-related quality of life were derived from the literature. Transition probabilities, prevalence and incidence rates were calculated using a large national database. An optimistic and a pessimistic implementation scenario were compared to a base case scenario with only standard care.
Results: In both the optimistic and pessimistic scenario, the intervention is cost-effective and dominant compared to standard-care: savings were €108,681,985 and €51,770,060 and the benefits were 1382 and 695 QALYs respectively.
Conclusions: The Kidney Team at Home intervention has been shown to be cost-effective compared to the standard care. This is caused by the superior health effects and the reduction of costs associated with transplantation, and the relatively small incremental costs of the intervention. Successful nationwide implementation of the intervention could lead to an increase in the demand for transplantation and to a reduced need for dialysis facilities in the Netherlands.

Abstract# 975

Implementation of the Kidney Team at Home Intervention: Evaluating Generalizability, Implementation Process, and Effects

S. Redeker[1], S. Ismail[1], R. Timman[1], J. van Busschbach[1], C. Boonstra[2], H. F. Brulez[3], D. A. Hollander[4], L. Hilbrands[5], F. J. Bemelman[6], S. P. Berger[7], J. van der Wetering[8], R. A. van den Dorpel[9], M. A. Jansen-Dekker[10], W. Weimar[8], E. K. Massey[8], *[1]Psychiatry, Erasmus MC, Rotterdam, Netherlands, [2]De Viersprong, Rotterdam, Netherlands, [3]Internal Medicine, OLVG, Amsterdam, Netherlands, [4]Internal Medicine, JBZ, Den Bosch, Netherlands, [5]Internal Medicine, Radboud UMC, Nijmegen, Netherlands, [6]Internal Medicine, Amsterdam UMC, Amsterdam, Netherlands, [7]Internal Medicine, UMCG, Groningen, Netherlands, [8]Internal Medicine, Erasmus MC, Rotterdam, Netherlands, [9]Internal Medicine, Maasstad Ziekenhuis, Rotterdam, Netherlands, [10]Internal Medicine, ZGT, Almelo, Netherlands*

Purpose: Research has shown that a home-based educational intervention for patients with chronic kidney disease results in better knowledge and communication on all treatment options, and more living donor kidney transplantations (LDKT) compared to care-as-usual. The aims of this study were (1) to demonstrate generalizability, (2) evaluate the implementation process in terms of feasibility, fidelity and intervention costs, and (3) to assess the relationship of the intervention effects on LDKT-activity.
Methods: Between 2016-2018, eight hospitals in the Netherlands participated in an implementation project. Patients eligible for all kidney replacement therapies (KRT) were invited to participate with their social network. Effect outcomes were KRT-knowledge and KRT-communication, and treatment choice. Feasibility, fidelity and intervention costs were assessed as part of the process evaluation. Cox-regression was used to assess the relationship of intervention effects on LDKT-activity.
Results: 812 patients were approached, and 332 patients completed the intervention. There was a significant increase in KRT-knowledge and KRT-communication among patients and invitees. After the intervention, 129 out of 332 patients (39%) had LDKT-activity. Overall participation rate was 40.9%. Protocol adherence was high (4.61 out of 5) and intervention costs were between €2500 and €3000 per intervention. Protocol adherence, knowledge and a lower age were positively correlated with LDKT-activity.
Conclusions: Results of the present study are comparable to the previous RCTs. These results show that the intervention can be implemented in multiple regions, while maintaining impact and quality. Results from the implementation process also support a nationwide implementation of the intervention. We recommend including home-based education in standard-care for patients with chronic kidney disease.

Abstract# 976

Living Donor Total Robotic Renal Transplantation: Early Single Center Experience

M. E. Tobon Lascano, S. Koganti, M. E. Akoad, M. Anastopoulos, C. J. Simon, B. A. Bouthot, E. D. Walshe, Y. L. Cheah, *Transplant, Lahey Clinic, Burlington, MA*

Purpose: To establish the feasibility and evaluate the results and outcomes of a newly established totally robotic kidney transplant program.
Methods: Retrospective review of a single center experience at living donor totally robotic kidney transplants performed between January to October 2020. We evaluated the recipient demographics, Donor/graft characteristics, Intraoperative details

including Cold Ischemia time (CIT), Warm Ischemia Time (WIT), Complications, Length of stay (LOS), Pain scores per visual analogue scale (VAS) on day 0,1,3, average Urine output (UOP) on first postoperative day and creatinine at days 7-10.
Results: A total of 5 totally robotic kidney transplants were performed during the established time frame. Recipient and donor characteristics are reported on table 1. The mean CIT was 51.2 minutes and the WIT was 43.6 minutes. Mean UOP on the first 12 hours was 7640 ml. The average VAS at day 0, 1 and 2 was 1.4, 3.2 and 3.6 respectively. Creatinine measurements between days 7-10 had a mean of 1.38mg/dl. The only recorded complication was acute cellular rejection type Banff 1A in one patient that resolved with standard medical management. The Average LOS was 5 days with no re-admissions or recorded wound complications.
Conclusions: Our early experience with living donor totally robotic kidney transplant shows that after adequate candidate selection the use of this technique is safe with reproducible outcomes and no procedure related complications. Additionally we showed rapid recovery and excellent graft function. Further investigation with a bigger cohort of patients and comparison to other techniques as well as learning curve for training physicians is needed."$$table_"

Abstract# 977

Detrusor Reinforced Lich-Gregoir Ureteroneocystostomy for Kidney Transplants Recipients: Comparative Analysis of the First 100 Cases

R. H. Astolfi, J. Medina-Pestana, H. Tedesco Silva Junior, W. Aguiar, *Urology, Universidade Federal de São Paulo, São Paulo, Brazil*

Purpose: In this study, we describe and compare the postoperative outcomes of our modified Lich-Gregoir ureteroneocystostomy (mLG), without DJ stent and with early bladder catheter removal, with the traditional technique.
Methods: Data from 100 consecutive patients who underwent mLG with early (48 hours) bladder catheter removal between October 2018 and November 2019 were compared to a control group (LG) comprised by the last 165 consecutive patients who underwent traditional Lich-Gregoir technique with routine (4-5 days) bladder catheter removal until July 2017. The same surgeon performed all surgeries and follow up was 6 months after transplantation. Surgical complications were stratified in early, occurring during the first month, and late.Differently from the traditional LG technique, in which the bladder mucosa is completely separated from the muscular layer, in our mLG the detrusor muscle is dissected in order to preserve a thin layer of detrusor fibers over the mucosa. Subsequently, the vesicoureteric anastomosis is performed by 2 separate continuous sutures of polidioxanone 6.0 between the spatulated ureter and the mucosa coated with detrusor fibers. Finally, the upper muscle layer is then loosely approximated over the distal portion of the ureter using interrupted 3.0 polyglactin sutures in order to create a tunnel that will serve as an anti-reflux mechanism.
Results: Patients in the mLG group were younger (37.4±13.7yo vs. 42±14.0yo, p=0.012) and had higher residual diuresis volume (911±753.8mL vs. 629±638.6mL, p=0.016). The incidence of diabetes was low and similar in both groups. There were no differences in chronic kidney disease etiology and time on dialysis was relatively short. Over 77% received a kidney from a living donor, and there were no differences in cold and warm ischemia time. There was a statistical difference in the distribution of the maintenance immunosuppressive regimen, with a lower proportion of patient receiving an mTOR inhibitor in the mLG group.After the transplant, it was observed that patients from the mLG group successfully underwent early indwelling Foley catheter removal (2.2±0.9d vs. 4.8±4.8d, p<0.001) and had a significantly lower hospital length of stay (6.5±5d vs. 7.1±6.2d, p=0.023), while also having lower rates of early surgical complication (3% vs. 17%, p=0.029). When analyzing specifically the occurrence of urinary leakages, we observed that in the mLG group there was only 1 case that resulted from necrosis of the entire ureter secondary to thrombosis of the graft's lower polar renal artery, while in the LG group there were 5 cases directly related to the vesicoureteric anastomosis.
Conclusions: The results of this study suggest that our modified Lich-Gregoir ureteroneocystostomy technique for kidney transplantation is a safe alternative to the traditional method, even with an early bladder catheter removal and without the use of DJ stents.

Abstract# 978

Single Center Experience in Ex Vivo Hilar Renal Artery Aneurysm Repair and Autotransplantation

A. Chang[1], K. Cederquist[1], P. Abt[1], G. Wang[2], B. Jackson[2], A. Naji[1], *[1]Transplant Surgery, University of Pennsylvania, Philadelphia, PA, [2]Vascular Surgery, University of Pennsylvania, Philadelphia, PA*

Purpose: In this study, we review our centers experience with complex renal artery aneurysms using our preferred technique of open nephrectomy, ex vivo repair, and autotransplantation in the pelvis.
Methods: The records of 11 consecutive cases of hilar RAA treated at our center between 2012 and 2020 were reviewed retrospectively. In each case, an open nephrectomy and partial ureterectomy was performed through an 8 cm flank incision. The affected organ was flushed with ice cold Belzer UW solution. Ex vivo resection of RAAs and reconstructions were performed on the back table in an ice bath. Autotransplantation was performed immediately after repair in the pelvis via a Gibson incision. Demographic data, intraoperative details, short term and long term outcomes are reported.
Results: During the study period, 11 ex vivo renal artery aneurysm repairs and autotransplantation procedures were performed in 10 patients. The median age of the patients was 56 years (interquartile range 47 - 66 years). Nine patients had at least 1 major cardiovascular comorbidity. The right kidney was involved in 5 cases, the left kidney in 6 cases. One patient had bilateral RAAs that were addressed in a staged manner. The total ischemia time was 303 ± 79 minutes. The mean aneurysm size measured by largest diameter in cross sectional imaging was 27.0 ± 8.5 mm. The mean pre-operative serum creatinine was 0.77 ± 0.14 mg/dL. Seven RAAs were repaired by aneurysmorrhaphy, 3 were implanted using a common patch, and in one case a combination of techniques was used. The mean serum creatinine at discharge on post-operative day 3 was 1.12 ± 0.98 mg/dL. Post-operative length of stay was 3 ± 0 days. Only one graft loss was reported due to microembolic disease in the kidney requiring graft nephrectomy. No patients progressed to chronic kidney disease or required dialysis during the study period. There were no deaths during follow up.
Conclusions: Ex vivo repair and autotransplantation is a treatment modality for complex hilar RAAs which has low complications and excellent outcomes.

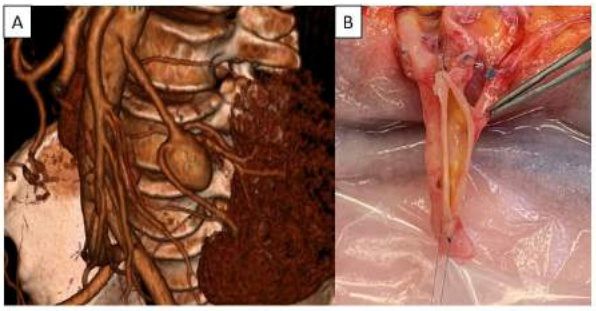

Figure 1: 3D reconstruction of hilar renal artery aneurysm (A) and ex vivo aneurysmorraphy repair (B) after nephrectomy and cold preservation.

Abstract# 979

Initial Experience with Single-port Robotic-assisted Kidney Transplantation

M. Eltemamy, A. Aminsharifi, Y. Lin, Z. Schwen, M. Abou Zeinab, V. Krishnamurthi, D. Goldfarb, A. Wee, J. Kaouk, *Cleveland Clinic, Cleveland, OH*

Purpose: Early experiences with multi-port robotic kidney transplantation have demonstrated a potential reduction in complications and improved convalescence while maintaining equivalent functional outcomes relative to the open approach. We present the technique and evaluate perioperative and short-term postoperative outcomes of single-port robotic-assisted kidney transplantation (RAKT) as a novel promising procedure to further reduce the morbidity of kidney transplantation.
Methods: We prospectively evaluate the perioperative and postoperative outcomes after single-port RAKT in patients who underwent primary kidney transplant (n=6) between November 2019-2020. Kidney allografts from living (n=4) and deceased (n=2) donors were transplanted into six patients. Single-port robotic surgery was done by placement of a GelPOINT system through a 5cm midline infraumbilical abdominal incision after developing the extraperitoneal space. The da Vinci SP® robotic system was used to prepare the vascular bed. After extracorporeal preparation of the allograft, the robot was undocked and the kidney was introduced into the extraperitoneal space followed by re-docking. The SP robot was used to complete vascular and ureteral anastomoses.

Results: Single-port RAKT was successfully completed without the need for conversion to any alternative approach in six patients with ESRD. Median age was 57 years (IQR: 55-60) with a median BMI of 28 (IQR: 23-37). Median operative time was 372 min (IQR: 367-439). Median arterial anastomosis time was 23 min (IQR:19-25) and Median vein anastomosis time was 28 min (IQR:28-29). Median hospital stay was 2 days (IQR: 2-3). Median Visual analogue score pain on discharge was 2 (IQR: 2-3). All patients had excellent graft function with serum creatinine levels at last follow- up ranging between 1.2-1.5 mg/dL.
Conclusions: Single-port RAKT is feasible with comparable short-term graft functional outcomes. Compared to the multiport robot, it offers the benefit of being a true single-site minimally invasive surgery as well as recapitulating the open extraperitoneal approach which might further reduce the morbidity of kidney transplantation. While these early results are promising, larger series with longer follow-up are required.

Abstract# 980

Anterior Rectus Sheath versus Gibson Incision for Kidney Transplantation - University of Chicago Experience

G. S. Generette, P. J. Bachul, P. E. Borek, K. Jayant, A. Perez-Gutierrez, B. Juengel, Y. T. Becker, R. Barth, J. Fung, P. Witkowski, *Surgery, University of Chicago, Chicago, IL*

Purpose: The advantages of Anterior Rectus Sheath (ARS) incision over traditional Gibson (GB) incision have been described for kidney transplantation. Therefore, we decided to compare those two incisions in regards to surgical site complication rates (SSC) in our center.
Methods: We analyzed retrospectively data from 45 subsequent adults submitted to unilateral kidney transplantation utilizing ARS incision and compared to outcomes in 99 subsequent adults treated with the same operation applying a standard GB incision. All procedures were performed by the same attending surgeon within last 3 years.
Results: There were significantly more patients 60 years old and older in ARS group- 55% comparing to 28% in GB group (p=0.006). Otherwise kidney donor and recipient characteristics did not differ between the groups. 60% of patients were male, median BMI was 27 (16-40), and 35% were diabetic. The donors were mostly deceased (90%), brain dead (54%) and median KDPI was 60%, (3-100). Delayed graft function rate was around 50% and length of hospital stay around (4-5 days) did not differed between the groups. The rate of surgical site complication (SSC) (wound infection or dehiscence) did not differ statistically: 14% in ARS vs 5% in GB group. All SSCs after ARS incision (6/6) were found in patient over 60 years old. Accordingly, SSC rate was significantly higher after ARS incision- 25% (6/24) in this age subgroup versus none after GB incision (p=0.002). In contrast, 80% of SSCs in GB group were found in obese (BMI>30) patients. Accordingly, the rate of SSC was significantly higher in GB versus ARS group in obese cohort: 12% vs 0 (p=0.015).
Conclusions: We found significantly less SSCs in obese patient subpopulation after utilizing ARS versus Gibson incision for kidney transplantation. However, Gibson incision was superior in patients over 60 years old resulting in significantly less SSCs.

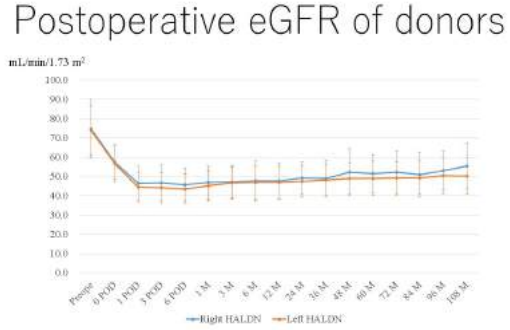
Abstract# 981

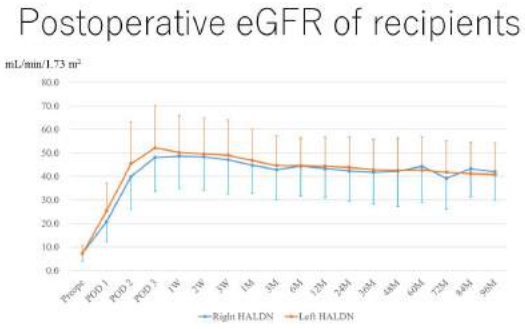
The Experience of 1000 Hand Assisted Laparoscopic Donor Nephrectomy for Living Donor Kidney Transplantation

T. Hiramitsu[1], T. Tomosugi[2], K. Futamura[2], M. Okada[2], N. Goto[2], T. Ichimori[2], S. Narumi[2], Y. Watarai[2], *[1]Nagoya Daini Red Cross Hospital, Myokencho Showaku, Japan, [2]Nagoya Daini Red Cross Hospital, Nagoya, Japan*

Purpose: Due to the profound organ shortage, living donor kidney transplantation becomes more necessary. Hand assisted laparoscopic donor nephrectomy (HALDN) is widely performed to lessen the burden of living donors. However, efficient and safe donor nephrectomy is essential. We investigated the efficacy and safety of right and left HALDN.
Methods: Between January 2008 and August 2019, 1018 living kidney donors underwent HALDN. Left and right HALDN were indicated for 957 and 61 living kidney donors based on the results of the kidney function in the 99mTc-DTPA scintigraphy. Operative results of donors and recipients were compared between right and left HALDN group.
Results: Significat difference was not identified in donor characteristics between left and right HALDN group. Operative duration and blood loss were similar in left and right HALDN group (212.7±98.4 vs 211.0±42.6min, P=0.892, 95%CI -26.595-23.165; 33.5±60.3 vs 60.0±189.1ml, P=0.284, 95%CI -22.537-75.463). Warm ischemia time was significantly longer in right HALDN group (133.6±69.4 vs 177.42.3 sec, P<0.001, 95%CI 26.479-61.766). Two and one open conversion were identified in left and right HALDN group (P=0.169, OR 1.44 95%CI 0.634-9.142). The incidences of other postoperative complications including adhesive intestinal obstruction (2 vs 0, P=0.060), incisional hernia (5 vs 2, P=0.646 , OR 1.416, 95%CI 0.526-3.814), bleeding (2 vs 0, P>0.999), and wound infection (88 vs 4, P=0.646, OR 1.416, 95%CI 0.526-3.814) were similar in both groups. Post-operative estimated glomerular filtration rates of living kidney donors were similar in both groups.



Post-operative estimated glomerular filtration rates of recipients were similar in both groups.



Only 1 delayed graft function due to the arterial injury during the left HALDN was identified.
Conclusions: The efficacy and safety of left and right HALDN were demonstrated through our experience of 1000 cases.

Abstract# 982

Urine Donor-derived Cell-free is Valuable for Predicting BK Polyomavirus-associated Nephropathy in Kidney Transplant Recipients

G. Huang[1], X. Chen[1], Y. Huang[1], J. Li[1], R. Deng[1], W. Chen[2], J. Qiu[1], S. Deng[1], G. Chen[1], Q. Fu[1], C. Wu[1], J. Fei[1], L. Liu[1], L. Chen[1], C. Wang[1], *[1]Organ Transplant Center, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China, [2]Department of Pathology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Purpose: Our previous study has proved that urine donor-derived cell-free DNA (dd-cfDNA) can assist in the diagnosis of BK polyomavirus-associated nephropathy (BKPyVAN), but its specificity is not clear. This prospective study was designed to evaluate the relationship between urine dd-cfDNA and various types of pathological damages in the transplanted kidney.
Methods: Urine dd-cfDNA quantification and proportion were respectively assayed from 96 patients receiving kidney transplant biopsies in our center. Dd-cfDNA was detected through Target Region Capture Sequencing and reads were calculated by Maximum Likehood Estimation.

Results: There was no significant difference in urine dd-cfDNA proportion among all groups (Figure 1A). Urine dd-cfDNA quantification was significantly higher in BKVN than Mixed-rejection (P=0.020), Borderline rejection (P=0.020), IgAN (P<0.001), IF/TA (P=0.003), and FSGS (P=0.042) (Figure 1B).
Receiver operating characteristic (ROC) analysis showed that the optimal cut-off value of urine dd-cfDNA quantification for predicting BKPyVAN was 6.08, with an area under the ROC curve (AUC) of 0.804 (95% confidence interval [CI]: 0.771-0.878) (Figure 2A). Youden index, sensitivity and specificity were 0.459, 0.778 and 0.681 respectively. ROC analysis exhibited that the optimal cut-off value of urine dd-cfDNA proportion for predicting BKPyVAN was 5.93%, with an AUC of 0.670 (95% CI: 0.566-0.762) (Figure 2B). Youden index, sensitivity and specificity were 0.340, 0.630 and 0.710 respectively.
Conclusions: Urine dd-cfDNA quantification was significantly increased in transplanted kidney with BKPyVAN. Urine dd-cfDNA has diagnostic value in predicting BKPyVAN.

Abstract# 983

Single Incision Simultaneous Liver Kidney Transplantation: Outcomes and Feasibility

D. Imai, Y. Sambommatsu, A. Khan, S. Lee, A. Sharma, V. Kumaran, D. Bruno, A. Cotterell, C. Bhati, M. F. Levy, *Virginia Commonwealth University, Richmond, VA*

Purpose: Simultaneous liver and kidney transplantation (SLK) is indicated in patients with concomitant end stage liver disease and severe chronic kidney disease or end stage renal disease. The number of SLK performed in USA has consistently been increasing in last few years. Traditionally SLK is performed using a subcostal incision for the liver allograft and a lower abdominal incision for kidney transplantation (Dual Incision, DI). At our institution, we perform a single subcostal incision (SI) for SLK. Aim of our study was to report our outcomes using single and dual incisions for SLK.
Methods: Retrospective analysis of all SLK done at our center from 01/2015 to 11/2020 was performed. Demographic characteristics, complications, intraoperative findings and complication after SI and DI were statistically compared. Further subgroup analysis was performed based on early and late experience with SI SLK.
Results: A total 34 SLK were performed (18 DI and 16 SI) during study period. MELD score, age, and indications for transplant were comparable in both groups. Recipient demographics, outcomes and comparison between two groups are shown in table 1 and 2. Patient in SI group had higher BMI without any statistical significance. Cold ischemic time of kidney transplantation was significantly shorter in SI group (p=0.002). The complications were slightly higher in SI group in early era without any statistical significance. Hospital stay, warm ischemia time were comparable in both groups. Post-operative morphine requirements and overall operative time in SI group was lower.
Conclusions: Single incision SLK is technically feasible and has comparable outcome to dual incision SLK. Single incision SLK was associated with shorter cold ischemia time for kidney transplant as well as lower overall operative time without any impact on outcome. Further study is required to delineate additional benefit of single incision SLK with particular focus on patient acceptance and recovery from the surgical wound.

Table 1 Comparison of single and dual incision SLK

	Dual Incision (n=18)	Single Incision (n= 16)	*p*-value
Age (mean ±SD)	57.1 ± 2.3	55.7 ± 2.5	0.697
Male	50%	56.3%	0.716
MELD score (mean ±SD)	28.2 ± 1.2	28.7 ± 1.3	0.759
BMI (mean ±SD)	27.3 ± 1.6	31.6 ± 1.7	0.080
KDPI (mean ±SD)	48.5 ± 6.3	43.0 ± 6.5	0.551
Operative Time (minutes)	511 ± 26	446 ± 28	0.098
WIT, kidney (min, mean ±SD)	29.3 ± 1.8	32.1 ± 1.9	0.283
CIT, Kidney (min, mean ±SD)	590 ± 28	450 ± 29	***0.002***
Hospital Stay (days, mean ±SD)	17.2 ± 5.5	25.6 ± 5.9	0.306
Morphine (mg Eq) at postoperative day 14	27.7 ± 5.4	16.4 ± 5.7	0.160
Complications			
Bile leak	0	3 (18.8%)	0.054
Bleeding	1 (5.6%)	2 (12.5%)	0.476
Clavien – Dindo grade ≥III complication	4 (22.2%)	7 (43.8%)	0.181
Mortality (1-month)	0	1

Abstract# 984

Is There a Role for Pre-Operative Angiographic Kidney Embolization Prior to Allograft Nephrectomy?

M. Jacobs[1], R. Stratta[1], D. Harriman[2], A. Farney[1], J. Rogers[1], G. Orlando[1], A. Reeves-Daniel[1], C. Jay[1], *[1]Wake Forest Baptist Health, Winston Salem, NC, [2]University of British Columbia, Vancouver, BC, Canada*

Purpose: To determine if morbidity associated with allograft nephrectomy (AN) of a failed or diseased kidney transplant (KT) is improved by pre-operative angiographic kidney embolization (PAKE).
Methods: We retrospectively reviewed adult KT recipients who underwent AN at our center from 2002-2020. Three patients whose grafts had auto-thrombosed at time of angiography were included in the PAKE group according to intention to treat. Ten patients, who underwent AN within 7 days of KT, and 2 patients, who underwent AN during repeat KT, were excluded.
Results: A total of 80 remaining patients underwent AN, including 54 (67.5%) who underwent PAKE prior to AN and 26 (32.5%) who underwent AN alone. Time interval between KT and AN was higher in PAKE patients (PAKE: 57±64 months vs AN alone: 24±44 months, p=0.02). Indications for AN included allograft intolerance (n=42), chronic graft infection (n=12), primary nonfunction (n=8), malignancy (n=8), late vascular events (n=7), and other (n=3). There was a trend toward more females in the PAKE group (PAKE: 58.5% female vs AN alone: 38.5%, p=0.1), but no other demographic differences were noted. PAKE was associated with significantly reduced blood loss (PAKE: mean 266±292 ml vs AN alone: 495±689 ml; p=0.04) and reduced transfusion requirements (PAKE: mean 0.5±0.8 packed red blood cell units vs AN alone: 1.6±2.6 units; p=0.004) despite comparable pre-operative hemoglobin levels. Mean operating time (PAKE: 141±43 minutes vs AN alone: 202±111 minutes; p=0.001) and mean length of initial hospital stay (PAKE: 4.3±1.9 days vs

AN alone: 9.3±9.4 days; p<0.001) both favored PAKE. PAKE was associated with a lower complication rate [11% (6/54); including vascular injury (2), re-exploration (1), small bowel obstruction (1), incisional hernia (1), and perioperative death (1)], compared to AN alone [38.5% (10/26, p=0.007); including vascular injury (2), wound complication (5), and re-exploration (3)].

Conclusions: PAKE was associated with less intra-operative blood loss, fewer transfusions, reduced operating time, shorter length of stay, and fewer complications compared to AN alone. More widespread use of PAKE should be considered to potentially reduce morbidity associated with AN. Further study is required to determine if allograft embolization alone as definitive therapy can prevent the need for AN in patients with complications of graft failure.

Abstract# 985

Robotic Assisted Donor Nephrectomy: A Single Center Experience

A. Khan, A. Sharma, S. Lee, A. Cotterell, D. Kumar, L. Kamal, I. Moinuddin, D. Bruno, V. Kumaran, M. Levy, C. Bhati, *Transplant Surgery, Virginia Commonwealth University, Richmond, VA*

Purpose: Robotic donor nephrectomy (RLDN) is an emerging procedure of choice for living kidney donors at many programs. This approach has benefit of minimal invasive surgery as well improved ergonomic movements for the surgeon, 6-degrees of freedom, precision and 3-D vision. The purpose of this study was to evaluate the technical feasibility and safety of non-hand assisted robotic donor nephrectomy in living donors and assess our outcomes.

Methods: Retrospective review was conducted in patients who underwent RLDN from 02/2016 to 12/2019 at our center. All relevant demographic and perioperative data was collected. Postoperative course including renal function before surgery and 2 weeks post-surgery, with all complications and additional long-term follow up were evaluated.

Results: A total of 141 donor robotic nephrectomies were performed at our center during study period. Majority of them were females (65%) with median age of 43 years(range 18-71 years). Thirty-nine donors underwent right donation and 102 had left kidney donation based on their vascular anatomy and size. Median operative time was 191 minutes(123-334 minutes). Multiple arteries and veins noted in 26 and 19 patients respectively. Average estimated blood loss was 37 cc. No donor required any blood transfusion. Predonation average creatinine was 0.83mg/dl and at 2 weeks 1.29mg/dl. Median hospital stay was 2 days (2-5 days). Nausea was most common complication(21%). Three patients had chest pain and two patients hypertension in early postoperative period. One patient had gluteal muscle rhabdomyolysis managed conservatively. Three donors had arterial stump bleeding after stapling. None required conversion to open procedure. Two patients required readmission, one for severe constipation with abdominal pain and another had a pneumonia. No donor had Clavien-Dindo 3 or higher complication.

Conclusions: RDLN is safe procedure with excellent outcome. The application of robotic technique to donor nephrectomy allows for greater control and maneuverability allowing it to be a safe and attractive option for both patients and surgeons.

Demographic Data	
Number of donors	141
Age (median)	43(18-71)
BMI(mean ± SD)	27.1 ± 4.3
Race (Black/white/others)	39/96/6
Maritalstatus (single/married/divorced)	36/90/15
Sex(M/F)	92/49

Intraoperative complications		
Stump bleeding	3	Managed with clipping or new staple fire
Gall bladder injury	1	Suture repaired
Early ureter transaction	1	Kidney implanted without any problems
Spleen capsule tear	1	Stopped with temporary pressure and argon beam

Abstract# 986

Robotic versus Open Mini-incision Living Donor Nephrectomy: Single Center Experience

S. Lee[1], S. Z. Wang[2], A. Khan[1], A. Sharma[1], D. Kumar[3], L. Kamal[3], A. Cotterell[1], V. Kumaran[1], D. Bruno[1], M. Levy[1], C. Bhati[1], *[1]Transplant Surgery, Virginia Commonwealth University hospital, Richmond, VA, [2]Medical School, Virginia Commonwealth University, Richmond, VA, [3]Transplant Nephrology, Virginia Commonwealth University hospital, Richmond, VA*

Purpose: A minimally invasive approach is the gold standard for living donor nephrectomy (LDN). While robotic surgery is commonly used for native nephrectomies and urological procedures, robotic LDN is being performed at very few centers worldwide. The robotic platform allows three-dimensional imaging of the surgical site and precise replication of human hand movements scaled down. Robotic surgery is associated with less tissue manipulation and earlier recovery with minimal incision. The aim of this study is to compare the short-term clinical outcomes between robotic-assisted donor nephrectomy (RDN) and open mini-incision donor nephrectomy (ODN) at a single center.

Methods: From 2016 to 2019, 141 consecutive cases involving RDN were analyzed at our single center. Patient outcomes were compared with those from a historical cohort of 191 patients who underwent ODN (7-9 cm incision) from 2010 to 2015. Medical records, including demographics, operation factors, perioperative outcomes, and complications were reviewed retrospectively.

Results: The RDN and ODN groups had a mean age of 42.8 and 41.4 years old, respectively ($p = 0.31$) as well as a mean BMI of 27.1 and 27.2, respectively ($p = 0.76$). Left-sided donor nephrectomy was performed in 102 patients (72.3%) via robotic approach and 88 patients (44.7%) via open approach ($p < 0.001$). Operative time was similar between both groups (194.0 for RDN vs. 197.8 min for ODN, respectively; $p = 0.40$). The RDN group presented with less blood loss than the ODN group (37.5 vs. 79.3 ml; $p = 0.023$). There was no open conversion case in the RDN group. Postoperative creatinine and glomerular filtration rate were not significantly different between two groups (1.28 and 61.68 for RDN vs. 1.28 mg/dL and 64.26 ml/min for ODN; $p = 0.996$ and 0.098, respectively). Length of hospital stay was significantly shorter in the RDN group than the ODN group (2.34 vs. 3.08 days; $p < 0.005$). The overall rate of complications was low and there was no statistically significant difference in complication rates between the groups. Complications included stump bleeding (3 for RDN vs 1 case for ODN, $p = 0.313$), urinary retention (1 for RDN vs 3 cases for ODN, $p = 0.643$), and lymphatic leak (1 for RDN vs. 0 case for ODN, $p=0.417$).

Conclusions: RDN is a safe and minimally invasive technique with excellent clinical outcomes for living donors. The robotic approach has benefits over the traditional open approach, including shorter length of hospital stay and reduced intraoperative blood loss.

Abstract# 987

Evaluation of the Impact of Delayed Graft Function (dgf) on Kidney Allograft Outcomes

J. Leeds, B. Rawashdeh, M. Sestito, B. Sharma, J. Kamal, A. Kumar, A. AgarwalAA4VB, A. Doyle, S. Rao, *University of Virginia, Charlottesville, VA*

Purpose: DGF is an important post-transplant complication that has early and long-term consequences on graft survival with increased relative risk of graft loss. DGF frequency varies widely worldwide ranging from 2-50% with the variability likely stemming from differences in rates reported by different national registries and type of donor. We sought to further evaluate effect of DGF on graft survival and glomerular filtration rate (GFR) at 1 and 3 years

Methods: We conducted a single-center retrospective chart review of deceased donor kidney transplants recipients from March 2013 to June 2017. Baseline patient demographics, transplant characteristics were collected. The recipients were grouped into two based on IGF vs DGF. Data was analyzed on SAS version 9.3.

Results: Of 184 recipients included in the study, 104 had IGF and 78 had DGF. The mean age was 53.5, 65.9% male, 40% Caucasian and 41.2 African American which was similar between the groups. The comorbidity burden in the cohort was high with 63.7% DM, 99% HTN and was similar amongst the groups. The mean donor age was 38.6, 25 were donation after cardiac death (DCD), mean KDPI was 53.8. At 3 year follow up, there was 9 patient death and 19 all-cause kidney allograft loss. On

univariate logistic regression, DGF status did not impact 3 year patient or allograft survival. On linear regression, DGF had an negative impact on GFR at 1 year and 3 year post-transplant. with GFR being lower by 8ml/min/1/73m^2 (p=0.01) (Figure 1).
Conclusions: We found that in recipients of deceased-donor kidney transplants, non-Caucasian race was associated with and increased risk of DGF. DGF was not associated with significantly different 3 year patient or graft survival, but did associate with worse kidney allograft function, with lower 1- and 3- year GFR measurements.

Table 1: Linear Regression Model for GFR at 1- and 3-years post-transplant

	GFR at 1 year		GFR at 3 years

Abstract# 988

Early Recovery After Surgery Protocol in Kidney Transplantation is Associated with Decreased Hospital Stay and Improved Clinical Outcomes

Y. Lin, M. Eltemamy, K. Sasaki, V. Krishnamurthi, D. Goldfarb, A. Wee, *Cleveland Clinic, Cleveland, OH*

Purpose: Early recovery after surgery protocols (ERAS) has been adopted in many surgical procedures. In 2018 we introduced transplant ERAS to our institution. It included modified preoperative counselling, strict fluid replacement, earlier discharge, outpatient dosing of induction immunosuppression and intensified postoperative follow-up.
Methods: We retrospectively reviewed 817 patients who had kidney transplantation only in our department from 2015 to 2020 with at least 6 months follow-up. Patients were divided into 2 groups; Group 1 from 2015 to 2017 (n=369) and Group 2 from 2018 to 2020 (n=448)
Results: Patients in Group 2 were older (56 vs 53 years, p<0.01) and had fewer living donation (32.3% vs 44.6%, P<0.01). They had a lower rate of delayed graft function (DGF) (8% vs 16.8%, P<0.01), decreased length of stay (3 vs 5 days, P<0.01) with a higher creatinine level at discharge (3 vs 2 mg/dl, P<0.01) but similar creatinine levels (p=0.1) and better graft survival (99.3% vs 96.5%, P<0.01) at 6 months follow up.
Conclusions: Our ERAS protocol was associated with a lower rate of DGF, decreased length of hospital stay, and better graft survival at 6 months. The higher creatinine at discharge can be explained by the lower percentage of living donation as well as the earlier discharge.

Abstract# 990

Anterior Rectus Sheath versus Standard Gibson Approach to Kidney Transplantation: A Randomized Double-blinded Controlled Trial

P. Murthy, M. Lyon, M. Fascelli, M. Spinner, E. Miller, Y. Lin, D. Goldfarb, V. Krishnamurthi, A. Wee, M. Eltemamy, *Glickman Urological and Kidney Institute, Cleveland Clinic, Cleveland, OH*

Purpose: Purpose: The anterior rectus sheath (ARS) approach to kidney transplantation (KT) involves a small skin incision to incise the ARS and medially retract rectus musculature, exposing the extraperitoneal space without cutting muscle. Retrospective literature demonstrated decreased wound-related complications compared to the standard Gibson approach (GA). Herein we present preliminary results from a randomized double-blind controlled trial comparing approaches for patients with at least 6 months follow-up.
Methods: Methods: Patients above age 18 without prior ipsilateral KT were enrolled. Surgeons randomized patients intraoperatively. Participants were not given additional incision-specific details apart from the fact that they were receiving one of two muscle splitting approaches. Data collection and analysis were blinded. Student's t-test and Chi-square were used to compare continuous and categorical data, respectively. The primary endpoint was wound complications and associated admissions; secondary endpoints were post-operative pain and analgesic requirements.
Results: Results: 59 ARS and 56 GA patients were reviewed (Table 1). Demographic data, total operative and anastomotic time, benched kidney volumes, pain scores and length of stay did not differ between groups. The ARS group had smaller incisions (p<0.01) and potentially less inpatient narcotic use (p=0.053). 3 patients in the ARS and none in the GA group had a wound related complication (p=0.34). One ARS patient was re-admitted for fascial dehiscence, and two had superficial skin dehiscence requiring bedside skin re-approximation.
Conclusions: Conclusions: At interim analysis of patients with 6 month follow up, wound related complications did not differ between the ARS and GA groups. Patients undergoing ARS may require less inpatient narcotic use despite having similar subjective reporting of pain.

Table 1 – Demographic, Peri-operative, Post-operative, and Wound Related Data

	ARS (n=59)	Gibson (n=56)	p-value
Mean Age (years, std. dev.)	55.4 (14.2)	51.0 (13.7)	0.09
Mean BMI (kg/m^2)	28.2 (5.0)	29.0 (5.3)	0.40
Dialysis Status			0.06
Intermittent Hemodialysis	37 (63%)	23 (41%)

Abstract# 991

Application of Incisional Wound Vac to Decrease Wound Complications and Surgical Site Infections: A Single Center Pilot Project

E. K. Venniro, M. Dokus, J. Taylor, R. Kashyap, *University of Rochester Medical Center, Rochester, NY*

Purpose: Wound complications and surgical site infections (SSIs) are common but morbid complications of transplant in immunosuppressed patients. Kidney transplant patients who are obese, highly immunosuppressed and diabetic are at further risk. These patients often end up with open incisions that require return to the OR, antibiotics, and weeks of routine dressing changes. New technologies, such as incisional wound vacuum assisted closure (VAC) devices, have been proven to reduce SSIs and wound complications other surgical fields. This aim of this pilot project was to study the impact of this technology in the kidney transplant population.
Methods: Based on a historical cohort of kidney transplant patients at a large academic medical center, risk factors for wound complications were analyzed to inform inclusion criteria for incisional wound VAC (IWV) application. Patients with 1) BMI over 35 or 2) BMI over 30 and history of diabetes or thymoglobulin induction had an IWV applied with a JP drain during the transplant operation. The incisional vac was left in place for 7 days post-discharge. Patients were monitored for surgical site infection or fluid collection requiring intervention.
Results: Between August 2019 and October 2020, 37.9% of our transplant patients met criteria for IWV placement. Eleven patients were able to be included in this pilot project. Four (36%) met criteria based on BMI≥35 all of whom were diabetic, one (9%) for BMI 30-35 & diabetes, and six (55%) were included for a BMI 30-35 & thymoglobulin induction. One patient's IWV had to be removed early due to skin blistering. Three patients (27%) in the higher risk IWV group had a wound complication, in line with the overall benchmark. Over that time period, the programmatic SSI rate decreased from 14.1% to 10.1% (figure 1) and a reduction in wound complications from 32.9% to 22.5% (figure 2).
Conclusions: A clinically significant decrease in the number of wound complications and SSIs was demonstrated over the study period. Though limited by small sample size and non-randomized design, incisional wound vacs appear safe to use in kidney transplant recipients. Further study is warranted to elicit the full impact of this technology in a population at high risk for wound complications.

Abstract# 992

Early Experience with Machine Retrograde Perfusion of Deceased Donor Kidneys: Short-term Outcomes of a Prospective Study

J. Zeng, Q. Zhong, S. Yin, Z. Jia, Z. Huang, Y. Fan, X. Wang, T. Lin, T. Song, *Urology Institute and Organ Transplantation Center, West China Hospital, Chengdu, China*

Purpose: To maximize the utilization of potential kidneys, improving perfusion and preservation technique is necessary. This article mainly investigated the safety and efficacy of retrograde machine perfusion of kidneys from deceased donor.
Methods: Twenty-four kidneys were included and all grafts were preserved in the LifePort Kidney Transporter. Twelve donor kidneys received retrograde perfusion (RP) were selected as the RP group, and their counterparts received standard antegrade perfusion (AP group). Perfusion pressure, flow, resistance, immediate graft function status, urine output, and renal function in first month were compared
Results: All recipients were followed up for one month. There was no primary non-function in both groups. No difference in the incidence of delayed graft function was found in both groups (3 in RP vs 2 in AP, $p = 0.62$). Both groups had comparable urine output, serum creatinine, estimated glomerular filtration rate, cystatin c, and blood urea nitrogen at any time point within 30 days. No wound infection and urinary fistula were observed in the two groups. Renal resistance in RP group remained stable during the perfusion. There was no difference in ultrasonic arterial resistance at one week between both groups. Patients in RP group with resistance < 0.4 had numerically better renal function than those with resistance ≥ 0.4.
Conclusions: Kidneys receiving retrograde machine perfusion had comparable outcomes to those receiving antegrade perfusion, indicating this novel technique may be an effective and safe alternative for kidney preservation.

Abstract# 993

Initial Experiment of Self-expanding Metal Ureteral Stent in Recurrent Ureteral Stenosis After Kidney Transplantation

Q. Zhong, T. Song, J. Zeng, Y. Fan, X. Wei, T. Lin, *Urology Institute and Organ Transplantation Center, West China Hospital, Chengdu, China*

Purpose: Expanding metal ureteral stent has been proven to be effective in the treatment of ureteral stenosis (US). However, its application in US after kidney transplantation (KT) is rarely reported. Here we described our experience of self-expanding metal ureteral stent in the management of recalcitrant US after KT.
Methods: We conducted a retrospective review of all patients with diagnosis of US after KT received treatment of Allium® ureteral stent at the West China Hospital, from January 1st, 2019 to May 31st, 2020.This study was approved by Ethics Approval Committee of West China Hospital.
Results: 15 patients with US diagnosis received self-expanding metal ureteral stent placement procedures and followed up for 8 months (rang,2-20). The ureteral stricture segments were located in the distal and the ureterovesical anastomosis site for all 15 cases, and the length was 2.2±1.0 cm. The procedure time for the stent placement was 71.4±29.3 minutes. After the procedure, two patients had fever, and no one developed urinary sepsis. Immediate ultrasonography did not reveal any further hydronephrosis and all patients had stable renal function. One month after the procedure, three patients had stent migration, with one returned to normal after reinserting, and the other two migrated again one month later and have to remove the stent. All other patients had stent in-situ at the last follow up. The overall success rate was 86.7%.
Conclusions: This study indicated that self-expanding metal ureteral stent is an effective treatment for US following KT

Kidney

Kidney Living Donor: Selection

Abstract# 1000

The Differential Impact of Size Mismatch in Live versus Deceased Donor Kidney Transplant

A. J. Vinson[1], T. Skinner[2], B. Kiberd[3], D. Clark[1], K. Tennankore[1], *[1]Division of Nephrology, Department of Medicine, Nova Scotia Health Authority, Halifax, NS, Canada, [2]Department of Urology, Nova Scotia Health Authority, Halifax, NS, Canada, [3]Dalhousie University, Halifax, NS, Canada*

Purpose: The risk of significant weight mismatch between donors and recipients (D-R) undergoing living donor kidney transplant (LDKT) is not well established. Further, how this risk compares with deferring LDKT for a weight matched deceased donor kidney transplant (DDKT) is unknown. Therefore, the purpose of this study was to determine the risk of D-R weight mismatch in LDKT and how this relates to deferring LDKT to facilitate a weight matched DDKT.
Methods: We used multivariable Cox proportional hazards models and the Scientific Registry of Transplant Recipients to determine the association of weight mismatched D-R (>50 kg, 30-50 kg or 10-30 kg ((D<R); (D>R); and <10 kg (D=R)) with death-censored graft failure in LDKT recipients in the USA from 2006-2017. We explored outcomes in weight mismatched LDKT D-R relative to weight matched (< 10 kg difference) DDKT D-R (separately for i. all deceased donors and ii. only standard criteria deceased donors (SCD)). Finally, we explored the impact of combined D-R weight-sex mismatch in LDKT versus weight and sex-matched DDKT.
Results: In LDKT, the risk of graft loss was increased in the setting of extreme D<R weight pairing (HR 1.282, 95% CI 1.053-1.560 for >50kg difference relative to D=R), but minimal if recipients were up to 30k larger than their donor (HR 1.059, 95% CI 0.977-1.149). However even in the highest risk LDKT D-R weight pairing, graft loss was still less than in weight-matched DDKT (HR 0.646, 95% CI 0.541-0.772 for >50 kg D<R LDKT compared with all D=R deceased donors; HR 0.745, 95% CI 0.617-0.899 for >50 kg D<R LDKT compared with only SCD D=R deceased donors), Figure 1a & b. D-R sex and combined weight-sex mismatch in LDKT was only important for male recipients (HR 1.472, 95% CI 1.265-1.712 for a male recipient >30 kg larger than their female donor, relative to weight-matched male donor-male recipient). This remained superior to weight-sex matched DDKT however.
Conclusions: D-R weight mismatch is important in LDKT, however graft survival remains superior to proceeding with weight matched DDKT. The same is true for weight-sex mismatch in LDKT versus weight-sex matched DDKT. Optimizing D-R matching in LDKT could be facilitated through a national kidney paired donation registry.

Abstract# 1001

Pediatric Kidney Transplant Strategy: The Sequence Effect

A. J. Vinson[1], B. Kiberd[2], P. Acott[3], K. Tennankore[1], *[1]Nova Scotia Health Authority Division of Nephrology, Departm, Halifax, NS, Canada, [2]Dalhousie University, Halifax, NS, Canada, [3]IWK Health Center, Halifax, NS, Canada*

Purpose: Improvements in patient survival with pediatric end stage kidney disease (ESKD) predicts needing more than one kidney transplant over a child's lifetime. Timing of utilization of willing live donor transplant (LD) relative to a deceased donor transplant (DD) remains controversial. Considerations under the current Allocation System notes pediatric DD transplant rates and organ quality are higher than in adults, graft failure rates are higher in adolescent recipients, and smaller children may have transplant hypoperfusion leading to worse graft outcomes. Families perceive benefit to the LD-backup option in case the first DD transplant fails. The best strategy is unclear.
Methods: Evaluation of 3 transplants over a lifetime, using a Markov model applied to USRDS data, evaluated patient and graft survival. Accounting for reduced transplant candidate eligibility over time and inputting current transplant rates, projected remaining life years (LYs) after transplant were calculated for 3 options: 1) LD-first (LD-DD-DD) with DDs if needed; 2) LD-backup (DD-LD-DD); or 3) No-LD (DD-DD-DD) in recipients age 3 to 30 years.
Results: Opting for a LD-first provided more LYs than the LD-backup option for most recipients (Table 1). The LD-backup sequence was slightly better in recipients age 7 to 15 years, Figure 1. However, the LD-backup advantage disappeared if LD availability changed, candidacy for DD altered (e.g. sensitization), or if pediatric DD transplant rates were lower. The No-LD group produced the fewest LYs for each age category. The Table also shows how many DD organs were used for the 3 options.
Conclusions: LD-first is best for most pediatric recipients, although LD-backup is slightly better for a subset age 7 to 15 years. Preferential, LD-backup equates to more DD organs utilized by pediatrics and not available for others on the waitlist. Pediatric LD utilization (first or backup) leads to more LYs compared to DD only organ options. The lesson is to 'utilize LD when you can'.

Table 1. Predicted Remaining Life Years (and total DD kidney requirement) for Selected Options

Age (years)	LD-first (DD Kidneys)	LD-backup (DD Kidneys)	No-LD (DD Kidneys)	Net Differences (DD Kidneys) [LD-first vs LD-backup] [LD-first vs No-LD]
3-5	50.22 (0.85)	48.99 (1.23)	46.73 (1.94)	1.23 (0.38) 3.49 (1.09)
5-10	48.94 (0.85)	47.91 (1.23)	45.64 (1.93)	1.03 (0.38) 3.30 (1.08)
10-15	44.90 (0.80)	45.38 (1.22)	43.00 (1.89)	-0.48 (0.42) 1.90 (1.09)
15-20	41.22 (0.68)	41.29 (1.13)	38.95 (1.69)	-0.07 (0.45) 2.27 (1.01)
20-25	37.98 (0.53)	36.41 (0.97)	34.54 (1.58)	1.57 (0.44) 3.44 (1.05)
25-30	34.68 (0.40)	32.04 (0.90)	30.87 (1.22)	2.63 (0.50) 3.81 (0.82)
30	31.20 (0.30)	28.12 (0.85)	27.03 (1.11)	3.08 (0.56) 4.17 (0.81)

Abstract# 994

Barriers to Living Kidney Donation: A Closer Look at Declined Donors

M. Anand, S. Barhorst, S. Bumb, B. Abu Jawdeh, T. Kaur, A. Govil, *University of Cincinnati, Cincinnati, OH*

Purpose: Medically complex donors are increasingly being assessed for donation. Due to concern for donor safety, there is a wide variation amongst transplant providers in the acceptance criteria for these candidates. In this study, we review the reasons for declining living kidney donor candidates, identify trends and determine quality improvement initiatives to streamline the live kidney donor evaluation process.
Methods: Data was collected retrospectively on all live donor (LD) candidates evaluated in donor clinic at our center from January 2019 to October 2020. Multiple medical reasons for donor denial were defined as the presence of 2 or more risk factors for progression to chronic kidney disease (CKD). Donor withdrawal was defined as a potential donor who was evaluated in clinic, but did not proceed with donation for various reasons.
Results: 291 individuals were evaluated for potential living kidney donation, of which 63 % were female and 45% older than 50 years. Out of these LD candidates, 94 (32.3%) were approved for donation while 197 candidates (67.7%) were declined. The reasons for declining donor candidates are shown in Figure 1. About 46% potential candidates did not proceed for donation due to either the presence of multiple medical conditions (23.3%) or donor withdrawal from the evaluation process (22.8%). The most common risk factors for CKD were obesity, pre-diabetes and hypertension. Interestingly, 45/197 (22.8%) potential donors who withdrew from the donation process (Fig 2), 35% did not proceed with donation either due to recipient ineligibility or the recipient received a deceased donor transplant. 31% withdrew due to undefined personal reasons, 18% pulled out due to concern for CKD post donation despite being considered as an acceptable medical risk and 16% lost contact after the initial clinic visit with no further follow-up.
Conclusions: Medical risk factors are widely recognized as a common reason for donor denial due to the lack of long-term safety data. However, we were surprised to find that donor withdrawal constituted a significant roadblock to donation. Further analysis revealed several modifiable factors that influenced donor decisions. In addition, we noticed variation among providers for acceptance criteria despite center-based guidelines for donor evaluation. To overcome these barriers , we propose a dedicated multi-disciplinary living donor team to identify risk factors that can be mitigated by donor education, counseling and primary care intervention. We believe that such a dedicated team will also avoid inter-provider variability and further streamline the process of live donor evaluation.

Abstract# 995

Development and Validation of a Nomogram for Remnant Kidney Function After Living-donor Donation

M. Dou, P. Tian, B. Zheng, G. Deng, Y. Shi, C. Ding, *The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*

Purpose: This study was to develop and validate a nomogram to predict remnant kidney function after living-donor kidney donation.

Methods: We conducted a retrospective cohort study on living kidney donors in our centre from 1999 to 2018.All donors were medically fit to donate and met Chinese donor selection criteria for donation. A favorable outcome was defined as post-donation eGFR at 1 year > 60% of the pre-donation eGFR.For nomogram construction and validation,all the donors were randomly divided into two cohorts in a 7:3 ratio,including training cohorts and validation cohorts .Then we identified independent prognostic factors using univariate analysis and multivariate logistic regression models.A nomogram for predicting 1-year eGFR was constructed based on these identified prognostic factors.The performance of the nomogram was validated both internally in training cohort and externally in validating cohort.The concordance index (C-index) and the receiver operating characteristic curve (ROC) were used to evaluate the discriminative ability of the nomogram. We used calibration curves to compare the actual outcomes with the predicted probabilities.

Results: Age and pre-donation eGFR were identified in univariate analysis. Next,these significant ($p<0.05$) factors identified in the univariate analysis were in the multivariate analysis,and multivariate analyses were performed via multivariate logistic regression. Age and pre-donation eGFR were significantly identified in multivariate analysis.Finally, a nomogram was constructed by incorporating these two independent predictors.The C-indexes for eGFR predicion in the nomogram were 0.84 and 0.81 for the training set and validation set.The calibration plot showed good agreement between the actual observations and the predicted outcomes both in training set and validation set.

Conclusions: This model might be a simple, but useful guide to predict remnant kidney function after donation,which could be an important clinical tool to improve the selection of living donors.

Abstract# 996

Body Surface Adjusted vs Raw GFR in Predicting Long Term Outcomes of Kidney Donors. Who is Disadvantaged?

H. N. Ibrahim[1], S. A. Hebert[1], H. E. Adrogue[1], D. Murad[1], D. T. Nguyen[2], E. A. Graviss[2], *[1]Medicine, Houston Methodist Hospital, Houston, TX, [2]Pathology and Genomic Medicine, Houston Methodist Hospital, Houston, TX*

Purpose: KDIGO and others recommend that GFR level acceptance (typically >80 ml/min) should be adjusted for body surface area (BSA) as GFR correlates highly with body size. This probably results in a wider acceptance of those with BSA <1.73 m^2 and lesser access for those >1.73 m^2 since adjusted GFR will be higher in the former and lower in the latter. Herein, we describe whether indexing GFR by BSA correlates with long term donor outcomes more accurately than raw GFR.

Methods: We compared the development of hypertension, proteinuria, reduced eGFR, ESKD and mortality in 5504 donors whose adjusted and raw GFR were >80 ml/min with 256 donors with only adjusted eGFR >80 ml/min, 1086 donors with only raw eGFR >80 ml/min and 1730 with both adjusted and raw <80 ml/min.

Results: In total 35% of donors had an adjusted eGFR <80 ml/min. Those with adjusted GFR > raw GFR were more likely to be women, had a lower BMI, lower SBP and DBP. Mean follow-up was 16 ± 11 years. The multivariable analysis revealed that donors with both eGFR <80 ml/min are more likely to die and reach eGFR <30 and <45 at last follow-up. Those whom only adjusted eGFR >80 ml/min did not incur increased risks of the outcomes studied. In contrast, donors with only raw GFR >80 ml/min and those with both GFR methods <80 ml/min were more likely to develop an eGFR <45 ml/min during follow-up.

Conclusions: More women are accepted when adjusted eGFR >80 ml/min is used. Donors with both adjusted and raw <80 ml/min and donors with only raw >80 ml/min were more likely to reach an eGFR <45 ml/min but had similar risk of mortality, hypertension and proteinuria. We see no major advantage for indexing GFR by BSA and it clearly results in over selection of those with smaller body frame.

Multiple logistic regression analysis: reference group is donors with both adjusted and raw GFR >80 ml/min

Outcome (events/ donors)	Adjusted eGFR ≥80 only		Raw eGFR ≥80 only		Both eGFRs <80	
	aOR (95% CI)	p-value	aOR (95% CI)	p-value	aOR (95% CI)	p-value
Mortality (418/ 8578)	1.71 (0.80, 3.62)	0.17	1.46 (0.96, 2.24)	0.08	1.64 (1.13, 2.38)	0.01
Hypertension (3182/ 8577)	1.20 (0.84, 1.71)	0.33	1.05 (0.86, 1.24)	0.60	1.07 (0.91, 1.25)	0.40
Proteinuria (1075/ 7684)	0.80 (0.48, 1.34)	0.40	1.08 (0.87, 1.33)	0.51	1.19 (0.98, 1.46)	0.08
eGFR <45 (1610/ 8371)	1.69 (0.87, 3.31)	0.12	3.73 (2.99, 4.65)	<0.001	8.65 (7.01, 10.67)	<0.001

Covariates included: age, gender, BMI, SBP, fasting plasma glucose, smoking, donation year. Post-donation diabetes and hypertension were adjusted for as time-dependent covariates.

Abstract# 997

Criteria and Practice Patterns for Accepting Living Donors with Prior Covid-19: A National Survey

A. Jawed[1], M. Y. Jan[2], N. Barros[2], O. Adebiyi[2], A. Diez[3], J. Fridell[2], W. Goggins[2], M. Yaqub[2], M. A. Mujtaba[4], T. Taber[2], V. Kumar[5], K. Lentine[6], A. Sharfuddin[2], *[1]Wayne State University, Detroit, IN, [2]Indiana University School of Medicine, Indianapolis, IN, [3]The Ohio State University, Columbus, OH, [4]UTMB Galveston, Galveston, TX, [5]University of Alabama, Birmingham, AL, [6]St. Louis University, St. Louis, MO*

Purpose: A critical question facing transplant programs is if, when and how to safely accept living kidney donors (LKD) who have a history and recovered from COVID-19 Infection. The purpose of the study is to understand current practices related to accepting living donors for donation who have recovered from COVID-19.

Methods: We surveyed US transplant programs from September 3, 2020 through November 3, 2020 by e-mail and postings to professional society list-serves. Center level as well individual opinion based responses were analyzed.

Results: A total of 174 US respondents from 115 unique centers responded, representing 59% of US Living Donor Programs and 72.4% of 2019 and 71.9% of 2020 LKD volume (as of October 31, 2020). Respondent Roles included Nephrologist (53.4%); Surgeon (19.5%); Infectious Disease (11.5%); Coordinator (9.8%).

Overall during the survey period, 48.6% of responding centers had received inquiries from such LKDs, while 44.3% were currently evaluating such donors. A total of 98 donors were reported to be in the evaluation phase, while 27.8% centers had approved a total of 42 such donors to proceed with donation.

Conclusions: Selection practices and criteria for LKD who have recovered from COVID-19 are variable. Ongoing research and consensus building are needed to guide optimal practices to ensure the safety of accepting such donors.

Responses for Questions Related to Donor Evaluation Who Have Recovered from COVID-19	
Accepting LKD who have recovered from COVID-19?	Yes (53.4%), Case-by Case (38%); Decline/Unsure (6.3%)
Accept LKD with past COVID-19 for Non-Directed Donation	Yes (62%); Unsure (28%); No (7.5%)
Accept LKD with past COVID-19 for KPD.	Yes (68.4%); Unsure (22.4%); No (7.5%)
Accept LKD with past COVID-19 for High Immunological Risk Recipient	Yes (63.8%); Unsure (26.4%); No (8.0%)
Minimum Time From Onset of Infection To Evaluation	>3mo (39.1%); >2mo (13.2%); >1mo (34.5%)
Minimum Time from Onset of infection to Donation Surgery	>3mo (48.9%); >2mo (11.5%); >1mo (27%)
Consider Additional testing ?	Chest CT (65%); PFT (51%)
Any other COVID-19-Specific testing During Evaluation ?	IGM (29.3%); IGG (52.3%); Antigen (16.1%)

Responses for Questions Related to Recipients who Receive COVID-19 recovered LD Kidneys	
Modify Immunosuppression protocol ?	NO (64%); Case-by-Case (14%); Unsure (15.5%)
Screen Recipient for COVID-19 Post-Transplant ?	No (51.7%); Yes 42.5%)
If screening, time frame to Screen ?	<1mo (71%); >1mo (20.5%); >2mo (1.4%); >3mo (1.4%)
If Screening, Type of Test ?	NP-PCR (35.6%); IGM (12%); IGG (12.6%); Antigen (10%)

Abstract# 998

Kidney Transplantation from Offspring to Mothers is Not Associated with Adverse Outcomes

S. Parajuli, N. Garg, A. Djamali, D. Mandelbrot, *University of Wisconsin, Madison, WI*

Purpose: Due to concerns of donor-specific alloimmunization during pregnancy, some have suggested avoiding living donor kidney transplants (LDKT) from offspring to biological mothers. Published analyses of UNOS data have yielded conflicting results, but there is limited data from single centers, which can provide more granular baseline information to perform adjusted analyses. In this study, we analyzed outcomes of offspring transplants to mothers.
Methods: All LDKT between 2013 and 2017 from our transplant program were analyzed. Offspring to mother transplants were defined as cases and two groups of controls were selected in a 1:1:1 ratio. Control 1 was offspring to biological fathers, matched for recipients age and DR mismatch and control 2 was all other remaining living donors, matched for recipients age, DR mismatch and HLA mismatch (out of 6).
Results: There were a total of 511 LDKT during the study period, of which 19 were cases, 19 (out of 43 fathers receiving offspring kidneys) matched LDKT were selected as control 1, and of the remaining 449, 19 matched LDKT were selected as control 2. Most of the recipients' baseline characteristics were similar between the groups. Not surprisingly, donors were significantly younger in cases (37.6 yrs) and control 1 (36.2 yrs) compared to control 2 (51.5 years) $p < 0.001$. There was no difference in the percentage of LDKT with pre-transplant DSA, mean HLA mismatch out of 6 or 12, or DR or DQ mismatch between the groups. Mean post-transplant follow-up was no different between groups. A total of 7 LDKT developed denovo DSA and 9 had acute rejection, with no significant difference between the groups. 1-year graft and patient survival was 100% in all three groups. There were a total of 6 graft failures at last follow up, 1 among the cases, 1 in the control 1, and 4 in the control 2 ($p=0.2$). The total number of patients with graft failure or eGFR <45 were similar between the groups: case (4), control 1 (3), Control 2 (8) ($p=0.15$). This was further confirmed by the K-M survival analysis curve (Figure 1). Similar results were obtained using as the composite endpoint graft failure or rejection or eGFR <45.
Conclusions: Although our data was limited by a small sample size, we present detailed information about offspring kidney transplants and do not find evidence of adverse outcomes in offspring to mother kidney transplantation. Because of potential emotional motivations for offspring to donate directly to their mothers, we do not believe that such transplants should be discouraged, especially in the absence of detectable DSA.

Figure 1: Outcomes at last follow up, graft failure or eGFR < 45

Abstract# 999

Early Experience with Broad Renal Genetic Testing in an Academic Transplant Center

E. Tantisattamo[1], K. Brossart[2], N. Ioannou[2], S. McCormick[2], P. R. Billings[2], H. Tabriziani[2], *[1]Division of Nephrology, Hypertension and Kidney Transplantation, Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA, [2]Natera, Inc., San Carlos, CA*

Purpose: Genetic testing is an emerging tool in kidney transplantation (KT), particularly to assess risk of recurrent disease in patients with KT and for selection of a living-related kidney donor. Studies highlight the benefit of using a broad, unbiased panel over using a selected targeted panel based on the clinical presentation of the disease.
Methods: A total of 19 patients, aged 23-69 years, who underwent genetic testing using a commercially available 382-gene renal panel in August and September, 2020 were included in this study. Of the 19 patients, 13 were awaiting transplant and 6 recently received transplants. Samples were analyzed using next-generation sequencing and variants were confirmed by orthogonal methods (eg, Sanger sequencing). Genetic testing results were interpreted by certified genetic counselors (cGCs) and was correlated with other clinical parameters.
Results: Monogenic variants associated with kidney disease were identified in 16% (3/19) patients (Table 1). All conditions identified using the 382 gene renal panel test confer increased risk of extrarenal manifestations for which the patients

were not being monitored previously. Additionally, 42% (8/19) of the patients were identified as heterozygous carriers of autosomal recessive conditions with potential reproductive risk implications.

Conclusions: Genetic testing resulted in the diagnosis of conditions that had previously not been identified based on clinical presentation alone. These findings demonstrate the benefit of using the broad renal genetic test in the transplant setting. Furthermore, genetic testing results can support patient management and enable identification of at-risk family members, such as living-related kidney donor. Integrating renal genetic tests in KT and future studies will expand our understanding of monogenic contributors to end-stage renal disease (ESRD) and guide pre- and post-KT management.

Genetic testing results and associated clinical condition for 3 identified monogenic etiologies

Age	Gender	Clinical History	Gene(s) identified	Inheritance	Condition
35	M	ESRD, liver ascites, hepatorenal insufficiency	*AVPR2*	X-linked	Nephrogenic diabetes insipidus
36	M	ESRD, seizures, renal angio-myolipoma	*PKD1, TSC2*	Autosomal dominant	Polycystic kidney disease with tuberous sclerosis complex
23	M	KTR returning dialysis after graft loss	*INF2*	Autosomal dominant	Focal segmental glomerulo-sclerosis (FSGS) type 5, intermediate Charcot-Marie-Tooth disease E with FSGS

Abstract# 1002

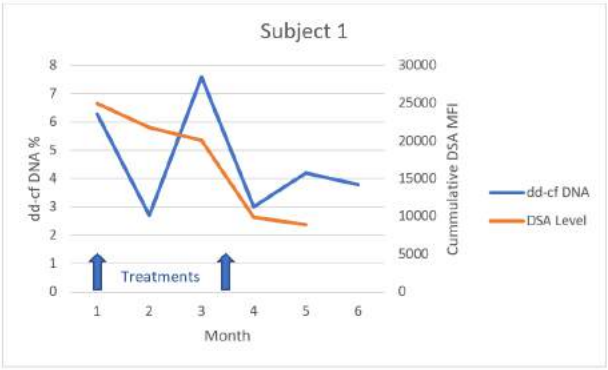
The Use of Donor Derived Cell Free DNA in Children to Monitor Therapy of Kidney Rejection

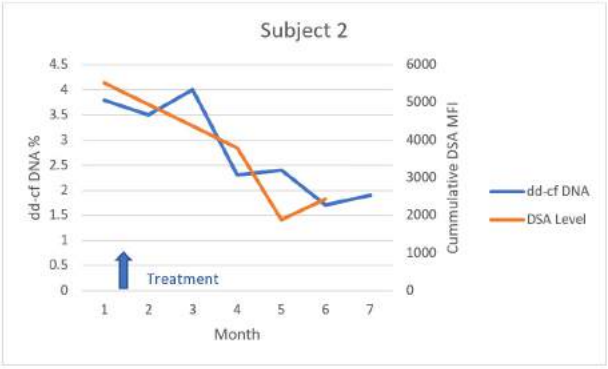
A. Al-Uzri, M. Wright, K. Clark, R. Jenkins, *Oregon Health & Science Univ, Portland, OR*

Purpose: Elevated donor-derived cell-free DNA (dd-cfDNA) in the presence of HLA donor-specific antibodies (DSA) are shown to correlate with acute antibody-mediated rejection (AMR) in adult and pediatric kidney transplant recipients. A dd-cfDNA result of > 1.0% is considered positive for acute rejection but data about changes in dd-cfDNA after AMR treatment in children remain scarce. The objective of our study is to assess the changes in dd-cfDNA over time after therapy of AMR in children with kidney transplant. We report the preliminary results of two patients who participated in the study.

Methods: This is a longitudinal non-interventional study in children < 21 y with biopsy-proven AMR and positive DSA. Our center's standard therapy for AMR consists of steroids, rituximab, and 3-5 monthly intravenous gamma globulin (IVIG) infusions, then quarterly as necessary. Persistent AMR is treated with additional plasma exchanges and bortezomib. DSA and dd-cfDNA tests were obtained before each IVIG infusion. We calculated the cumulative MFI by adding together the MFI of each single DSA. Statistical analysis used descriptive statistics.

Results: Two subjects accumulated enough data points to report. Subject 1 is a 14-year-old male who developed AMR 21 months post living unrelated kidney transplant. He was treated initially with steroids, rituximab, and IVIG. A repeat kidney biopsy showed evidence of persistent AMR and was treated with plasma exchange, bortezomib, rituximab, and IVIG (0.7-2 g/kg/dose X 7). He had two biopsies completed. Subject 2 is an 8-year-old male who developed AMR 37 months after a living-related transplant (documented by biopsy) and was treated with steroids, rituximab, and IVIG (1-2 g/kg/doses X 4). Creatinine remained stable in both subjects. Repeated measurements of dd-cfDNA and cumulative DSA-MFI were monitored over several months as in the following graphs





Conclusions: The dd-cfDNA test is a valuable tool to use after therapy of AMR when combined with HLA-DSA to monitor response to therapy and may preclude the need for a repeat kidney biopsy. Further studies in a larger population are in progress.

Abstract# 1003

Graft Loss in Adolescent and Young Adult Generation After Pediatric Kidney Transplantation: A Single Center Experience in Japan

Y. Aoki, Y. Hamasaki, M. Muramatsu, J. Hashimoto, M. Kubota, S. Shishido, K. Sakai, *Nephrology, Toho University Faculty of Medicine, Tokyo, Japan*

Purpose: Kidney transplant recipients of all ages may have difficulty adhering to a strict treatment plan, adolescents and young adults are at particularly high risk for poor adherence. In previous reports, young people also have the highest risk for graft failure of any age group. In recent years, attention has been focused on how to enhance medical care for the adolescent and young adult (AYA) generation, and measures for medical care and care for the AYA generation in patients with pediatric cancer, congenital diseases, and chronic pediatric diseases are important issues. Kidney transplantation (KT) is a beneficial treatment not only for the body but also for life stages for pediatric patients with renal failure, and it is thought that the way the AYA generation spends will greatly affect their lives thereafter. The aim of this study was to investigate patient background, employment and re-transplantation in the AYA generation of graft loss after pediatric KT.

Methods: We performed a retrospective cohort study on pediatric kidney transplant recipients, aged 15 years or younger, who received their first transplant between 1975 and 2009. Recipients were graft loss in AYA generation (15-40 years old) and followed from KT until the last known date alive as of May 2017.

Results: Among the 323 children who underwent first KT during the study period, 80 children (24.8%) were graft loss in AYA generation after KT. Forty-eight patients who continued to visit the hospital were included in this study. The median duration of follow-up was 25.0 years (IQR 20.3-31.0). The median age at first KT was 11.2 years (IQR 6.4-12.9) and median age at the time of graft loss was 21.7 years (IQR 19.1-26.0). The most common cause of graft loss was chronic allograft nephropathy (93.7%). The overall graft half-life was 11.8 years. Nonadherence to immunosuppressive medication was 16.7%, and the age of onset was 15 to 20 years old in 75%. However, there was no significant difference in graft survival by nonadherence (p=0.74). Overall, 29 patients (60.4%) were employed, 7 patients (14.6%) were married, and 3 patients had a baby. Of the 48 patients, 25 (52%) underwent second KT at median age of 25.8 years (IQR 22.3-28.5). Twenty-three patients (92%) had living kidney transplants, six patients (24%) had ABO-incompatible KT, and 13 patients (52%) had preemptive KT. The employment rate did not decrease, and five patients were married after re-transplantation.

Conclusions: Many patients who had graft loss in the AYA generation are forced to choose renal replacement therapy at a stage in their development of social independence. In our study, patients who were re-transplanted in the AYA generation were able to progress to social independence. Addressing the medical health care of the AYA generation of patients with end-stage renal failure is an important challenge for building a fuller life stage and a more productive society.

Abstract# 1004

Growing Up During the Pandemic: A New Look for Transitioning to Adult Transplant Care

M. M. Chandran, E. Blanchette, A. Sikora, M. Bisek, E. S. Christofferson, M. Bock, *Children's Hospital Colorado, Aurora, CO*

Purpose: Adolescent and young adult (AYA) recipients of solid organ transplants (SOT) are confronted with a unique set of life stressors that may negatively impact allograft outcomes. Regardless of age at time of transplant, AYA transplant recipients have a higher risk of graft loss compared to other age groups. A transition from pediatric to adult healthcare teams often occurs during this life period, potentially intensifying this challenging time. Recently the COVID-19 pandemic has compounded anxiety and stressors surrounding major life events, adding uncertainty and lack of normalcy for this population.

Methods: In 2016, our center implemented a comprehensive, multidisciplinary Transition-to-Adult-Care (T2AC) curriculum for AYA SOT recipients to facilitate successful transfer of care. This curriculum consists of longitudinal education, readiness assessment, outreach programming, and a day-long seminar focusing on education from pediatric and adult transplant providers, pharmacists, coordinators, social workers, and psychologists. "Graduates" of our curriculum demonstrate improved transplant outcomes in the first year following transition with decreased rejection episodes, de novo DSA formation, graft loss, loss to follow-up, ED visits and inpatient admissions, and fewer "bounce-backs" to the pediatric center [Abstract C221; Am J Transplant. 2019; 19 (suppl 3)]. Recognizing the need to continue preparing our AYA population for transition, despite limitations created by social distancing, we adapted the T2AC Transitions Seminar to a virtual platform. Patients and caregivers received virtual didactic education with visual aids, interacted with providers and peers, and received support from transplant psychology during focused break-out sessions.

Results: Despite changes in structure and platform, virtual programming was successfully implemented. This event boasted the highest attendance to date with 25 AYA recipients and additional family members participating; we hypothesize this was attributed to joining from a location of their choosing, precluding the need for travel. Additionally, active participation was notably increased, potentially related to multiple modes of online interaction (e.g. private/group chat message) and minimized anxiety by removing in-person interaction. A post-course survey indicated positive reception with an average response of 7.7 /10 (10 = Very Likely) to "How likely are you to attend a similar event again in the future?". The average response to "After attending this event, how prepared do you feel for transitioning to adult care?" of 6.7/10, comparable to 7.2 for prior in-person events, suggests change in venue did not reduce impact.

Conclusions: Given the overall positive experience, we plan to maintain and grow the virtual nature of our T_2AC Seminar through the pandemic and beyond, hoping to broaden our audience and strengthen our educational mission.

Abstract# 1005

Impact of Once-Daily Extended-Release Tacrolimus Intrapatient Variability in Stable Adolescent and Young Adult Renal Transplant Recipients - 3 Year Results

M. M. Chandran[1], E. Blanchette[1], J. Goebel[2], M. Bock[1], *[1]Children's Hospital Colorado, Denver, CO, [2]Helen DeVos Children's Hospital, Grand Rapids, MI*

Purpose: Successful renal transplantation requires complex medication regimens that rely heavily on strict adherence to be effective. Variability in immunosuppression exposure, specifically tacrolimus, is associated with poor allograft outcomes. Wide intrapatient variability of tacrolimus trough concentrations (Vtac) is likely, in part, attributable to poor medication adherence. Once-daily tacrolimus formulations create opportunity to simplify therapeutic regimens, and this study aims to evaluate their impact on Vtac, and ultimately transplant outcomes.

Methods: This retrospective cohort study investigated stable adolescent and young adult (AYA) renal transplant recipients converted from immediate-related tacrolimus (IR-Tac) to extended-release tacrolimus (ER-Tac). Subjects served as their own controls. Vtac was assessed prior to and at five time points post-conversion to ER-Tac over 36-month follow-up. Secondary outcome measures included graft function, infection rates, and effect on modifiable treatment-related factors.

Results: Twenty-eight AYA subjects were converted from IR-Tac to ER-Tac. Vtac significantly improved following conversion and was sustained for 36 months ($Vtac_0$ 2.32 vs. $Vtac_5$ 0.83, $p < 0.05$). Renal function remained stable and biopsy proven acute rejection (BPAR) rates were modest (14%). Mean pill burden was reduced by 15% and 42.9% of subjects achieved a once-daily medication regimen.

Conclusions: Conversion from IR-Tac to ER-Tac in this AYA population significantly improved Vtac with sustained effect over 3 years. This effect is likely attributable in part to simplification of the medication regimen and presumably improved medication adherence. Furthermore, such conversion does not appear to compromise graft function.

Abstract# 1006

Longitudinal Studies of Blood Donor-derived Cell Free DNA (dd-cfDNA) Show Predictable Rise at Time of BK Viremia or Viruria in Pediatric Kidney Transplant Recipients (PKTx)

R. Dandamudi[1], H. Gu[1], C. Goss[1], S. Federman[2], R. Woodward[2], S. Dholakia[2], L. Walther[1], V. Dharnidharka[1], *[1]Washington University in St Louis, St. Louis, MO, [2]CareDx, Brisbane, CA*

Purpose: Blood levels of dd-cfDNA elevate in various forms of kidney transplant injury, most notably used for detecting potential acute rejection. A few adult studies, largely cross-sectional, have described elevations at time of other injuries such as ischemic or infections (bacterial or polyoma BK virus). We hypothesized that dd-cfDNA had a discriminating role between BK Viruria and Viremia and can act as a surrogate marker to quantify the severity of viral injury for both diagnosis and management.

Methods: We have performed longitudinal biobanking of plasma and urine in our PKTx population since 2013, combined with monthly testing for urine BK virus DNA by PCR (switch to blood once urine is positive) from months 1-12 post-transplant. In this study we assayed longitudinal biobanked and prospective plasma samples for dd-cfDNA levels (Allosure; CareDx) and associated to standard of care longtitudinal BK viremia or viruria results, positive defined as any detectable DNA. Statistical analyses were performed via SAS using least squares means mixed modeling.

Results: In 257 urine and 257 plasma samples from 56 children (Males 57.1%, white 76.7%, deceased donor 67.8%), subjects with BK viruria within the first 12 months (sample n = 71/257 or 28%) showed a simultaneous higher plasma dd-cfDNA load (mean 0.77% versus 0.49%). Subjects with BK viremia within the first 12 months (sample n = 23/257 or 9%) showed a simultaneous higher plasma dd-cfDNA load (mean 1.24% versus 0.50%). By longitudinal analysis that accounted for within-subject variability, a rise of 0.80% (95% confidence intervals [CI] 0.3 to 1.28%) in dd-cfDNA levels were seen at time of BK viremia (p = 0.0014). A smaller non-significant rise of 0.32% (95% CI -0.01 to 0.66%) in dd-cfDNA levels were seen at time of BK viruria (p = 0.06). In 5 patients with BK viremia resolution, later dd-cfDNA levels dropped compared to levels at peak BK viremia (Figure).
Conclusions: In our PKTx cohort, where BK infection is more common than acute rejection in the first year, the longitudinal testing suggests that any BK viremia, but not BK viruria, causes sufficient renal allograft parenchymal injury to elevate the dd-cfDNA level above a given patient's baseline. Further, we can now quantitate the level of dd-cfDNA elevation needed to predict onset of viremia, allowing for targeted biopsies to determine BK nephropathy.

Abstract# 1007

Longitudinal Studies of Blood Anellovirus DNA Prior to Acute Rejection or Major Infection Events in Pediatric Kidney Transplant Recipients (PKTx)

R. Dandamudi, H. Gu, C. Goss, H. Gula, K. Wylie, V. Dharnidharka, *Washington University in St Louis, St. Louis, MO*
Purpose: Blood levels of the ubiquitous but non-pathogenic anellovirus (AnV) taxa have been postulated to represent a biomarker of the overall state of immunosuppression after transplantation. Prior studies, largely cross-sectional in adults, suggest that levels of the AnV rise with major infection events (MIE) and drop with acute rejection (AR).
Methods: We have performed longitudinal biobanking of serum in our PKTx population since 2013, combined with monthly testing for opportunistic viruses DNA by PCR from months 1-12 post-transplant and recording of clinical events. In this study we assayed longitudinal biobanked and prospective serum samples for AnV DNA levels (copies/mL) and associated to standard of care monitoring and clinical results. To adjust for repeated measurements within subjects, we used a linear mixed model approach to test for differences in AnV DNA levels between complication groups (None, MIE at time of sample, AR at time of sample). A log transformation was used to better meet model assumptions, and results are reported on the log scale.
Results: In 271 plasma samples from 46 children (Males 52%, white 83%, deceased donor 69%), as shown in **Figure**, most serum samples are positive for AnV through all time points. Further, box plots of longitudinal results in **Figure** show a slight increase in median AnV DNA levels at 2-4 months, the peak time period for opportunistic viral replication. Mixed model results showed that the log AnV DNA (copies/mL) was elevated by 0.5 log for the MIE group (adjusted mean of 17.3 [95% CI, 16.1 to 18.4]) compared to the no complications group (adjusted mean of 16.8 [95% CI, 15.9 to 17.7]) (P=0.41). In contrast, results for the AR group showed a lowering of log AnV DNA (copies/mL) (14.3 [95% CI, 15.9 to 17.7]) by 2.5 log compared to the no complications group (P=0.12). Although neither result was statistically significant (likely due to small sample size), both results are consistent with the concept from cross-sectional studies of AnV load as an immunosuppression state biomarker.
Conclusions: In our PKTx cohort, our results suggest that longitudinal AnV levels that account for within patient variability also seem to associate to AR and MIE events. Further prospective longitudinal testing in a larger multicenter cohort is recommended.

Abstract# 1008

The Impact of the Kidney Transplant Journey on Patient's and Parent's Identities and Self-Management

J. C. Dunbar[1], E. E. Bascom[2], W. Pratt[2], J. Snyder[2], J. M. Smith[3], A. H. Pollack[3], *[1]University of Washington Information School, Seattle, WA, [2]University of Washington, Seattle, WA, [3]Seattle Children's Hospital, Seattle, WA*
Purpose: Describe the experiences of pediatric patients and their families after kidney transplant. Our qualitative study aimed to understand (1) how these individuals describe and develop a "normal life" after transplant and (2) how this view affects their ability to self-manage.
Methods: Pediatric kidney transplant recipients and their families were recruited from a pediatric transplant center in the United States. All participants were asked to submit photographs related to when they feel: (1) worried, (2) confident, (3) similar to their peers without kidney disease, and (4) different from their peers without kidney disease. During interviews, participants were asked to share their experiences using the photos as prompts. Interviews were recorded, transcribed and analyzed using an inductive grounded theory approach to identify common themes.
Results: 10 pediatric kidney transplant recipients, ages 7-21 years, and 9 parents completed the study. All participants described the profound, life changing impact of the kidney transplant, resulting in periods of highs and lows. These changes led to the development of a new facet of their identities, both as individuals (a "kidney kid") and as a family unit (family/parent of a "kidney kid"). Our analysis identified five tensions that describe and form this new Kidney Identity: (1) exchanging information, (2) managing transitions, (3) building confidence, (4) telling their transplant stories, and (5) normalizing the transplant journey. As patients progressed through their transplant journey, tensions shifted depending on both their actual and perceived clinical status. Positive health outcomes increased feelings of self-confidence and personal security resulting in increased (1) interest and ability to express themselves, (2) willingness to share their story with others, and (3) capacity to build strong peer connections. Positive changes within their Kidney Identity led to improved self-efficacy, autonomy, and self-management, further improving their clinical status. However, as setbacks occurred, individuals regressed in one or more of the five Kidney Identity tensions, with negative consequences.
Conclusions: After kidney transplant, patients and families develop a new Kidney Identity that positively influences their ability to engage in self-management. In future work, we plan to longitudinally assess and identify an individual's movement within each of the five Kidney Identity tensions after transplant. We believe this will support self reflection on one's progress after transplant and help clinicians identify barriers which prevent successful patient and family engagement in their own care. Surfacing these five tensions and making them visible to all stakeholders has the potential to help patients, families, and clinicians ensure successful health outcomes.

Abstract# 1009

Outcomes of Granulocyte-Colony Stimulating Factor Use in Pediatric Renal Transplant Recipients: A Pediatric Nephrology Research Consortium Study

R. M. Engen[1], P. L. Weng[2], W. Shih[3], H. Patel[4], K. Richardson[5], S. Dowdrick[6], I. Ashoor[7], J. Misurac[8], A. Z. Traum[9], M. Semanik[10], N. G. Jain[11], R. Sreedharan[12], *[1]Northwestern University, Chicago, IL, [2]University of California Los Angeles, Los Angeles, CA, [3]University of Michigan, Ann Arbor, MI, [4]Nationwide Children's Hospital, Columbus, OH, [5]Oregon Health & Science University, Portland, OR, [6]Penn State Health, Hershey, PA, [7]Louisiana State University, New Orleans, LA, [8]University of Iowa, Iowa City, IA, [9]Harvard University, Boston, MA, [10]University of Wisconsin-Madison, Madison, WI, [11]Columbia University, New York, NY, [12]Medical College of Wisconsin, Milwaukee, WI*

Purpose: Neutropenia is common after pediatric kidney transplant and is associated with an increased risk of bacterial infection, allograft loss, and death. Granulocyte colony-stimulating factor (G-CSF) increases neutrophil production, but its use in pediatric solid organ transplant recipients remains largely undescribed.

Methods: Multicenter retrospective cohort study of pediatric renal transplant recipients with neutropenia, defined as absolute neutrophil count (ANC) <1500/mm^3 within 6 months after transplant. Multivariable linear regression compared outcomes between those who did and did not receive G-CSF.

Results: Of 341 neutropenic pediatric renal transplant recipients from 13 centers, 94 (27.6%) received at least one course of G-CSF. Median G-CSF dose was 5 mcg/kg for 3 (IQR 2-7) doses. G-CSF was given to 83 patients during their first episode of neutropenia while 11 were treated for recurrent neutropenia. Median time from neutropenia onset to G-CSF initiation was 7 days (IQR 2-16 days). Treatment with G-CSF was associated with transplant center, induction immunosuppression, steroid-free maintenance immunosuppression, ANC nadir, hospitalization, and decreases in mycophenolate mofetil and valganciclovir doses but was not associated with patient age or CMV or EBV viremia. While G-CSF was associated with a shorter duration of a neutropenia episode (p=0.026), there was a higher rate of recurrent neutropenia following G-CSF discontinuation (p=0.004). Total duration of neutropenia did not differ when the first and second episodes were combined (p=0.817). G-CSF was not associated with decreased bacterial infections, duration of hospitalization, incidence of rejection within 3 months of neutropenia, or increased eGFR at 1 year post-transplant.

Conclusions: G-CSF does not shorten the overall duration of neutropenia in pediatric kidney transplant recipients and is not associated with decreased rejection or improved eGFR. Additional studies are needed to determine which subset of transplant recipients would benefit from G-CSF treatment.

Abstract# 1010

Understanding Delays to Pediatric Kidney Transplant Wait-List Activation: Providers and Families Weigh in

C. M. Farkas-Skiles[1], A. Feinsinger[2], R. Pines[3], A. D. Waterman[4], *[1]Pediatric Nephrology, UCLA Mattel Children Hospital, Los Angeles, CA, [2]Medicine and Philosophy, UCLA, Los Angeles, CA, [3]Santa Barbara Cottage Hospital, Santa Barbara, CA, [4]Nephrology, David Geffen School of Medicine, UCLA, Los Angeles, CA*

Purpose: Since timely access to kidney transplant mediates mortality of children with kidney disease, we examined which factors most commonly affect providers' decision-making to delay wait-listing, compared provider and family perspectives about the importance of these factors, and determined recommendations to overcome factors affecting delays.

Methods: Using a mixed method design, 20 providers and 20 family members responded to 25 open-ended questions. 33 participants completed a survey of closed-ended questions on the importance of dimensions that delay waitlist activation. Interviews were analyzed using thematic analysis. Providers were 65% nephrologists, 10% coordinators, 15% surgeons or 10% social workers from 17 pediatric transplant centers. Families included patients who were post-transplant 50%, patients with history of dialysis 95%, single parent household 50%; patient ages ranged 2-21 years.

Results: Themes named by providers affecting waitlist delays included avoiding retransplantation, the presence of an unstable family environment, primary disease (e.g., FSGS), pervasive nonadherence and poor psychological readiness for transplant care. Families similarly described challenges related to family instability or patient health problems, which were often adherence or psychiatric-related. Although families generally agreed with providers' choices to delay waitlisting, they expressed stress and burdens from remaining on dialysis. These burdens, especially financial, raise ethical concerns that current practices may contribute to disparities in access to transplant. Families recommended earlier psychological treatment, positive relationships with coordinators, more social support, and financial help from governmental programs to reduce delays.

Conclusions: Both providers and families agree that stabilizing the family situation and adherence to treatment are important reasons to delay wait-listing. However, patients and family members need more support from transplant centers to overcome these challenges.

Table 1 Factors important to listing for kidney transplant

Percentage ranked factor important	Family	Provider
Knowledge of transplant complications	n/a	94%
Dialysis Adherence	60%	94%
Psychiatric adherence	73%	89%
Back up caregiver available	47%	67%
Phosphorus, Hemoglobin in goal	87%	47%
Literacy	93%	39%
Symptoms prevent school attendance	60%	28%

Abstract# 1011

Maternal Perinatal Condition and Neonatal Growth and Development After Renal Transplantation

X. Feng, T. Song, Q. Zhong, J. Zeng, X. Wang, Y. Fan, Z. Huang, T. Lin, *Department of Urology, Institute of Urology, Organ Transplantation Center, West China Hospital, Sichuan University, Chengdu, China*

Purpose: Although pregnancy and delivery after kidney transplantation have been reported in many studies , it is still little known about growth and development of neonates born to kidney-transplanted women.

Methods: We retrospectively included patients who became pregnant and gave birth after transplantation from October 2011 to November 2020, and matched post-transplant pregnant women with contemporaneous non-transplant pregnant women at 1:3 ratio by childbearing age, pregnant times, BMI and the mode of delivery in the same period.

Results: In this study, a total of 24 recipients received kidney transplantation at the average age of 25.5±3.3Y/O. from September 2005 to December 2017 and became pregnant and gave birth at the average age of 29.9±2.5Y/O. from October 2011 to November 2020. All mothers were natural fertilization with single fetus in both two groups. In spite of higher incidence of preeclampsia(TX vs non-TX: 20.8% vs 4.2%, relative risk/RR: 4.95) in kidney-transplanted group, the incidence of gestational diabetes mellitus, intrahepatic cholestasis of pregnancy (12.5% vs 11.1%, RR=1.13; 8.3% vs 6.9%, RR=1.20, respectively) were similar. Although, compared with non-transplanted group, the rates of low birth weight and premature birth (29.2% vs 0 and 75% vs 0, both p values<0.05, respectively) were much higher in kidney-transplanted group, there is no significant difference in weight and height at 1st, 3rd, 6th, 9th, 12th, 18th month after birth (weight(kg): 4.07 vs 3.99, 6.62 vs 5.97, 8.18 vs 7.51, 8.83 vs 8.25, 10.04 vs 9.00, 11 vs 10.12, respectively; length(cm): 52.94 vs 52.7, 60.26 vs 59.7, 66.38 vs 66, 70.6 vs 70.1, 75.48 vs 73.8, 78.85 vs 79.6, respectively, all p values<0.05) compared with 2009 Reference Standard for Growth and Development of Children under 7 years old in China publicated by Chinese MINISTRY OF HEALTH, even better numerically, which both lower numerically than that of WHO Standard though.

Conclusions: Although the rates of low birth weight and premature birth were far more than non-transplanted pregnancies, which was the same as the previous studies, the weight and length development of the neonates seems unaffected, which still needs more large- sample, long-term and random studies to confirm.

Abstract# 1012

Bortezomib for Antibody-Mediated Rejection of Renal Transplant in Youth

L. Galea, J. Hewlett, J. Savant, S. Lopez, S. Amaral, B. Viteri, *The Children's Hospital of Philadelphia, Philadelphia, PA*

Purpose: The purpose of the study was to examine preliminary efficacy and tolerability of bortezomib, a protease inhibitor, in treatment-refractory antibody mediated rejection (AMR) in pediatric kidney transplant patients.

Methods: Patients who received bortezomib (4 doses at 1.3 mg/m^2 per cycle) for AMR (per Banff 2017 criteria) at a large children's hospital over a 1.5 year period were included. Charts were abstracted for demographic and clinical data. Primary outcomes were change in donor specific antibodies (DSA) and estimated glomerular filtration rate (eGFR; based on bedside Schwartz formula) before, and 1 and 3 months after bortezomib. Descriptive statistics were performed.

Results: Six patients were included (baseline characteristics and outcomes summarized in Table 1). Two cycles of bortezomib were given as a 2nd line agent after increased baseline immunosuppression and other treatments (e.g., IVIG, rituximab, plasmapheresis, and/or thymoglobulin) failed to resolve DSA or improve renal function. Two patients had DSA resolution (30%) and 2 different patients showed improvement in eGFR (30%). Data collection is still ongoing for the remaining patients. No serious adverse effects were noted.

Conclusions: In this small, single-center study of bortezomib for refractory AMR in pediatric kidney transplant patients, we observed variable improvement in DSA and renal function. Bortezomib was well-tolerated, however efficacy evaluation was limited due to small sample size, lack of randomization, and short follow-up period. This study adds to the nascent but growing literature examining bortezomib for AMR in kidney transplanted youth.

Abstract# 1013

Predictors of Prolonged Length of Stay in Pediatric Kidney Transplantation: Changes Over the Last Three Decades

K. Goli, N. T. Galvan, R. T. Cotton, J. A. Goss, C. A. O'Mahony, A. Rana, *Department of Abdominal Transplantation, Baylor College of Medicine, Houston, TX*

Purpose: Hospital length of stay (LOS) following kidney transplantation, particularly prolonged LOS, has not shown much improvement since the early 2000s. This study explores changes in risk factors for prolonged pediatric LOS over the last 3 decades.

Methods: The UNOS database was queried for pediatric (age<18) kidney transplants between 1990 and 2020. Multivisceral transplants, retransplants, and living donor transplants were excluded and the final sample was 8229 patients. Risk factors for prolonged LOS were analyzed by decade using univariate logistic regression and those which were significant (α=0.05) were entered into a multivariate logistic regression analysis.

Results: Over the last 3 decades (Figure 1), recipient age has become an increasingly significant protective factor against prolonged length of stay. While dialysis during the waitlist period has become an increasingly significant risk factor for prolonged LOS, dialysis at time of transplant has become nonsignificant in the recent decade. Additionally in the recent decade, low recipient functional status (20%), African American or Asian ethnicity, and spending more than 1 year on the waiting list have become significant recipient risk factors for prolonged LOS. In contrast, having private insurance, autoimmune disease diagnosis, shortened cold ischemic time, high BMI, and being a dropout from school have become protective against prolonged length of stay (Table 1).

Conclusions: These findings suggest some improvements in pediatric kidney transplantation over the 3 decades, as shorter cold ischemic times are associated with shorter length of stay. Being on dialysis at time of transplant is no longer a significant risk factor for patients, which may suggest transplantation of healthier patients overall. Additionally, adolescents are possibly being discharged earlier with increasing confidence. However, waitlist time of more than 1 yr and dialysis during the waitlist period has become an increased risk factor, which may suggest longer waitlist times in recent years with more patients on dialysis becoming ill. This may explain the lack of improvement in prolonged LOS from 2000-2020.

Abstract# 1014

Improving Allograft Survival by Informing Donor Selection in Kidney Transplant Recipients Under 5 Years Old

F. Manca Barayre, L. Greenbaum, R. Garro, P. Winterberg, R. Patzer, J. Hogan, *Emory University, Atlanta, GA*

Purpose: The kidney allocation system aims at allocating high-quality kidneys in pediatric recipients but the KDPI score used to assess the quality of the donors may not accurately predict graft survival of pediatric recipients. We aimed at assessing KDPI accuracy to predict graft failure in pediatric recipients and at developing predictive models of graft loss for deceased and living donor transplants to inform donor selection.

Methods: We included all first-time, kidney only transplant recipients under 18 years old from the SRTR database receiving a transplant from an adult donor between January 2005 and August 2018. The primary outcome was graft failure, defined as dialysis, re-transplantation, or death with a functioning graft. Kaplan-Meier and Cox methods were used to assess KDPI accuracy in the overall cohort. To improve donor selection in children < 5 years old at kidney transplantation, we developed a Small Pediatric-KDPI (SP-KDPI) and Small Pediatric-Living KDPI (SP-LDKPI) on the same scale to compare each other by using Cox models adjusted for recipients characteristics.

Results: KDPI C-statistic was 0.52 (95% CI = 0.50 - 0.54) in all pediatric recipients of adult deceased donors kidneys and higher KDPI was not associated with higher rate of graft failure in recipients < 5 years old. Six deceased donor factors were included in the SP-KDPI computation (ethnicity, age, body surface area, gender, cold ischemia time, HLA-B mismatches number). Four living donor factors were included in the SP-LKDPI computation: race, age, HLA-B mismatch number and donor/recipient body surface area ratio. Model accuracies were validated internally by cross-validations and C-statistics were 0.64 (95% CI = 0.57 - 0.70) and 0.65 (95% CI = 0.58 - 0.73) for SP-KDPI and SP-LKDPI, respectively. Figure 1 presents allograft survival stratified by donor type and SP-(L)KDPI stratum. SP-LKDPI identified 16.8% of living donors with predicted graft survival superior to any deceased donor.

Conclusions: The current KDPI allocates good kidneys (< 35%) to pediatric recipients but provides little information to guide donor selection especially in recipients younger than 5 years old. We developed an adaptation of the KDPI that demonstrated a higher accuracy to predict graft loss in young recipients. We also developed an extension of this score to accurately compare adult living and deceased donors offered to young recipients.

Abstract# 1015

Treatment of Bk Virus With Intravenous Immunoglobulin in Pediatric Kidney Transplant

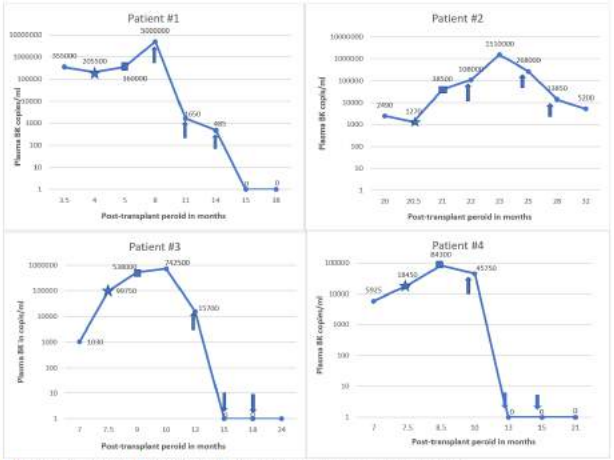
D. Mohammad, D. Kim, R. Baracco, G. Kapur, A. Jain, *Pediatric Nephrology and Transplant Services, Children's Hospital of Michigan, Detroit, MI*

Purpose: To study the prevalence of BK viremia (BKV) and BK Virus Nephropathy (BKVN) utilizing plasma BK quantitative Polymerase Chain Reaction (qPCR) and report outcomes of treatment with reduction of immunosuppression and intravenous immunoglobulin (IVIG).

Methods: A retrospective cross-sectional study of pediatric kidney transplants from January 2013 to January 2020. Excluded were age> 21 years at transplant and primary nonfunctioning allograft. Surveillance was conducted using plasma BK qPCR at 1,3,6,9,12,18,24 months and then annually. BKV was defined as ≥ 250 copies/ml, and BKV resolution as <250 copies/ml on consecutive blood draws at least two weeks apart. Persistent BKV was defined as ≥ 250 copies/ml at last follow up. Presumed BKVN was defined as persistent BKV ≥10,000 copies/ml despite immunosuppression reduction and elevated creatinine; confirmed BKVN if SV-40 stain was positive on biopsy. Chi-square, One-Way ANOVA, and Box-plot analysis was performed using SPSS 21.0.

Results: Inclusion criteria was met by 56 children. Demographics: mean age at transplant was 11.8±5.6 years; 68% male; 55% African-American; 75% deceased-donor; 91% primary transplant. Mean follow up was 42.5±22.5 months. All patients received thymoglobulin induction and tacrolimus-prednisone-mycophenolate mofetil (MMF) maintenance regimen. Twenty (35.7%) of 56 had BKV, two (3.5%) presumed BKVN and two (3.5%) confirmed BKVN. A comparison of BKV vs. Non BKV group revealed that mean age at transplant, gender, race, primary diagnosis, type of donor, re-transplantation status, HLA matching, cold ischemia time, thymoglobulin dosing, duration of stent, acute rejection and mean duration of follow up were not statistically significant. Mean post-transplant time (months) to initial detection (5.5±4.5), peak (8.5±5), and resolution (15±7) of BKV was noted. Reduction in immunosuppression was the first line of therapy in 100% patients. At initial detection of BKV, tacrolimus trough level was reduced to target range in 8(40%) and below target range in 1(5%). For those within tacrolimus target range, 5 (25%) had < 50% reduction and 7(35%) had ≥50% reduction in MMF dose. Four patients with presumed/confirmed BKVN also received 6 doses of IVIG each. 14/20 (70%) had BKV resolution. Mean eGFR (ml/min/1.73m^2) at the last follow up in BKV vs. Non-BKV group was 68.7±22 vs. 63.1±22.3; p=0.7, with 100% graft survival in both groups.

Conclusions: Screening for BKV using qPCR, stepwise reduction in immunosuppression and use of IVIG resulted in resolution of BKV and preservation of renal allograft function.



Immunosuppression reduction and IVIG treatment in Presumed/Confirmed BK Virus Nephropathy (n=4)

Abstract# 1017

Single Center Experience on SARS-CoV-2 Testing of Symptomatic and Asymptomatic Pediatric Kidney Transplant Recipients

H. Pizzo[1], P. R. Soni[2], S. Nadipuram[2], J. Garrison[1], D. Puliyanda[1], *[1]Pediatric Nephrology, Cedars-Sinai Medical Center, Los Angeles, CA, [2]Pediatric Infectious Disease, Cedars-Sinai Medical Center, Los Angeles, CA*

Purpose: As of late November 2020, there have been 61.5 million cases of SARS-CoV-2 (COVID-19) worldwide resulting in 1.44 million deaths. Despite the outstanding number of cases there is limited data on the incidence of SARS-CoV-2 infection, both symptomatic and asymptomatic, among pediatric (ped) kidney transplant (KTx) patients (pts) and their outcomes.

Methods: Between March and November 2020, 33 SARS-CoV-2 RNA RT-PCR tests were performed among 23 ped KTx pts who were maintained on mycophenolate mofetil, tacrolimus, +/- steroids. Pts were tested for SARS-CoV-2 if they had any COVID-19 symptoms, had positive COVID-19 contact, or needed SARS-CoV-2 testing for admission to the hospital or for pre-procedural clearance. No pts were tested more than once during each encounter.

Results: Of the 33 SARS-CoV-2 tests performed, 7 (21.2%) were due to pts having one or several COVID-19-like symptoms, while 26 (78.8%) were for pts who had positive COVID-19 contact or needed SARS-CoV-2 testing for admission to the hospital or for pre-procedural clearance. Of the 33 tests performed, there were 3 (9.1%) confirmed cases of COVID-19. Two of the 3 SARS-CoV-2 positive cases had symptoms consistent with infection, compared to one asymptomatic case ($p = 0.11$). The two positive cases with symptoms were on steroid-free immunosuppression, had estimated GFR (eGFR) of 101 and 60 ml/min/1.73m2, and were 0.9 and 3.1 years post-Tx, respectively. The one asymptomatic case was on steroid-based immunosuppression, had eGFR 85, and was 0.9 years post-Tx. No pts who tested positive for SARS-CoV-2 required hospitalizations. Five of the 7 pts (71.4%) with symptoms consistent with COVID-19 were eventually diagnosed with a different infection (bacterial and/or viral) and all required admission for management.

Conclusions: There is a low rate of asymptomatic SARS-CoV-2 (COVID-19) infection among our ped KTx cohort. When infected with SARS-CoV-2, ped KTx pts tend to present with minimal symptoms. In this small cohort, there appears to be no correlation between the time since Tx, eGFR, and the maintenance immunosuppression in relation to whether or not pts were more likely to have symptoms or have more severe disease if infected with SARS-CoV-2. Ped KTx pts with symptoms concerning for COVID-19 with clinical indications for admission were more likely to have alternative diagnoses. Larger studies are needed to understand the prevalence and impact of SARS-CoV-2 infection in the ped KTx population.

Table 1. Characteristics of Ped KTx Pts with SARS-CoV-2 Testing

	Total Tests (n=33)	Symptomatic (n=7)	Asymptomatic (n=26)	*p*
Total number of pts	23	7	16

Abstract# 1018

To Whom do Pediatric Donor Organs Go?

J. Smith[1], M. Skeans[2], R. Engen[3], S. Bartosh[4], *[1]Seattle Children's Hospital, Seattle, WA, [2]SRTR, Minneapolis, MN, [3]Lurie Children's Hospital, Chicago, IL, [4]Univ of Wisconsin, Madison, WI*

Purpose: Pediatric priority in organ allocation is mandated by the Final Rule, but prioritization varies by organ, sometimes informed by size-matching needs. Heart (Policy 6.6.E) and lung (Policy 10.4.D) policy dictate that organs from donors <18 years be allocated to pediatric candidates before adults. Liver (Policy 9.8.F, 9.8.G) policy prioritizes pediatric candidates for pediatric donor organs. Kidney policy has no such priority. Moreover, the kidney profile donor index (KDPI, a measure of donor quality) is limited by the exclusion of pediatric recipients in the model. A high proportion of pediatric donor organs with KDPI >35% results in allocation of pediatric donor kidneys to adults. We wanted to determine how often pediatric donor organs go to pediatric recipients.

Methods: We used SRTR data to classify donor and recipient age groups per organ. The cohort includes kidney, liver, heart, and lung transplant recipients, 2015-2019, whose deceased donor was <18 years. Donors were grouped as aged 0-5, 6-11, and 12-17 years, and recipients as pediatric (<18 years) or adult (≥18 years). We computed the proportion of organs that went to pediatric vs. adult recipients by pediatric donor age group.

Results: The proportion of pediatric recipients varied considerably by organ. Among young (<5 years) pediatric donors of livers, hearts, and lungs, nearly all recipients were <18 years old, but among 1795 kidney donors <5 years, only 4.1% of organs went to pediatric recipients (Figure 1). Among donors 6-11 years, 54.0% of livers, 92.5% of hearts, and 40.7% of lungs—but only 8.4% of kidneys—went to pediatric recipients. Organs from donors 12-17 years went primarily to adult recipients for all organs.

Conclusions: Current policy prioritizes pediatric recipients for pediatric donors of liver, heart, and lung. Absence of such prioritization of pediatric donor kidneys results in the allocation of most pediatric donor kidneys to adults. Development of a policy for pediatric donor kidneys, similar to pediatric donor liver, heart, and lung, will increase access for pediatric kidney candidates, particularly those that may benefit from size matching.

Abstract# 1019

Pediatric Kidney Transplant Recipients Frequently Experience Utis Regardless of Esrd Etiology

E. Spiwak, C. Nailescu, A. Schwaderer, *Indiana University Department of Pediatrics Division of Nephrology, Indianapolis, IN*

Purpose: Urinary tract infections (UTIs) remain the most common type of infectious complication experienced by renal allograft recipients. UTIs in transplant patients most commonly occur in the first year post-transplant, but recurrent episodes can occur due to various reasons. In the general pediatric population, *Escherichia coli* (*E.coli)* causes 80-90% of UTIs. The purpose was to review and understand the demographics of pediatric transplant patients who required hospitalization over a four-year time period at one center. UTIs in transplant patients are associated with acute rejection risk, chronic allograft nephropathy, and in some cases, urosepsis.

Methods: A chart review of 145 pediatric kidney transplant recipients was performed to retrospectively identify a total of 65 individual patients with a total of 191 hospital visits. Patients aged 3 to 21 years of age who are followed at the Indiana University Department of Pediatrics for kidney transplantation were included. Data was recorded for symptoms at presentation, urine lab results, and etiology of the underlying kidney disease that lead to end stage renal disease (ESRD).

Results: Out of 65 total patients included, 39 had a congenital anomaly of the kidneys and the urinary tracts (CAKUT). Obstructive uropathy was the ESRD etiology for 48% of children with CAKUT. Non-obstructive CAKUT included renal hypo/dysplasia and reflux nephropathy. The patients with CAKUT were younger and more likely to be male. Hospitalized pediatric transplant kidney recipients were diagnosed with UTIs at a rate of 30% for the 191 admissions reviewed. There were no statistical differences in the percentage that experienced UTIs or the number of UTIs per year between pediatric transplant recipients with and without CAKUT. *E.coli* was only responsible for 23% of the UTIs.

Conclusions: Among hospital visits for pediatric kidney transplant recipients, diagnosis of UTI occurred in almost one-third of admissions. The risk for UTI hospitalization appears to be similar regardless of ESRD etiology. The microbe profile for UTIs experienced by the transplant patients differed from those noted in UTIs in the general pediatric population, *E.coli* was less likely to the be the causative organism.

Patient Differences Between Those with Non-structural vs CAKUT Underlying ESRD Etiology			
	Normal Urinary Tract (n=26)	**CAKUT (n=39)**	**Difference Testing, p-value**
Patient Age at First Admission Mean (SD)	14.8 (3.78)	12.1 (4.81)	Mann-Whitney, 0.0389
Graft Age at First Admission Mean (SD)	3.4 (3.79)	3.4 (3.20)	Mann-Whitney, 0.6628
Sex (% Male)	42.3	85	Fisher, **0.004**
UTI During Any Admission % (contingency values)	35% (9/26)	38% (15/39)	Fisher, 0.7984
UTIs/year Mean rate (SD)	0.66 (2.05)	0.31 (0.70)	Mann-Whitney, 0.9664

Abstract# 1020

Kidney Allograft Outcomes in Pediatric Patients Transitioned to Adult Care - A Single Center Study

S. Subramanyam, G. Agarwal, M. Seifert, V. Kumar, G. Towns, K. Wille, S. Ong, *University of Alabama at Birmingham, Birmingham, AL*

Purpose: The transition of healthcare for young adults with kidney transplants from pediatric to adult care settings is an area of need, hitherto under-recognized in adult care centers. The outcomes of pediatric patients transitioned to adult care have not been studied rigorously and may help identify areas for intervention.
Methods: We performed a retrospective study to evaluate the outcomes of 29 kidney transplant patients who were transitioned from Children's of Alabama to University of Alabama at Birmingham between 1/1/2017 and 9/30/2020. Data are presented as medians and interquartile ranges where appropriate. Fisher's exact test was used to compare the difference pre and post transition. Statistical analyses were performed using JMP (Cary, NC).
Results: Out of the 29 patients, 61.1% were male, 45% were African American and 40% were White. Median age at transplant and at transition were 16.2 years (IQR 13.9-17, range 9-18.4). and 19.9 years (IQR 19.6-20.7, range 18.5-21.9) respectively and median age at last follow up was 21 years (IQR 20-22). Median time from transplant to transition was 4.3 years (IQR 2.5-5.0). Median creatinine and proteinuria at transition was 1.3 mg/dl (IQR 1.1-1.9) and 0.2 g/g (0.12-0.82) respectively. At the time of transition, ten patients (34%) had a history of rejection, 6 (21%) had a history of a positive donor-specific antibody (DSA). Nearly all patients received maintenance immunosuppression consisting of tacrolimus (93%), mycophenolate mofetil (86%) and prednisone (93%). Within 2 years following transition, 6 (20%) developed *de novo* DSA , 4 (14%) developed acute rejection and 4 (14%) developed graft failure (3 had acute and 1 had chronic rejection). All 4 graft losses occurred within 1 year of transition and of the 4, 3 had a pre-transition history of acute rejection and/or DSA. However DSA and rejection before transition and de-novo DSA post-transition were not predictive of graft failure within 2 years of transfer (p= 0.24 and 0.17 respectively). Pre-transition suspected non-compliance was strongly associated with rejection and DSA prior to transition (p <0.001 and p= 0.0011) but not with graft failure or de-novo DSAs post-transition (p=0.076 and p= 0.118).
Conclusions: A significant number of patients transitioning to adult care already have a history of organ rejection and DSA. At time of transition patients had minimal proteinuria and good graft function. In a 2 year period following transfer of care, graft loss rate was low. Prior rejection, DSA and non-compliance did not impact graft loss in the early post-transition period. Additional data is needed to verify this finding and to identify areas of intervention that may improve outcomes following pediatric to adult transition of care at our center.

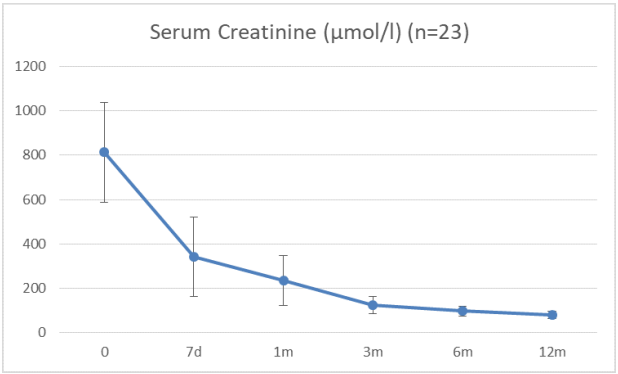
Abstract# 1021

En Bloc Kidney Transplantation from Pediatrics Weighing Less Than 5 Kg: Single Center Analysis of 31 Cases

Z. Wang[1], X. Zeng[2], Q. Xia[2], J. Peng[2], H. Xiao[2], J. Liu[2], H. Li[2], *[1]Urology, Huazhong University of Science and Technology, Union Hospital, Wuhan, China, [2]Urology, Union Hospital, Wuhan, China*

Purpose: Very low bodyweight pediatrics are rarely chosen as donors because of potential higher risk for complications such as early allograft thrombosis, and possible latter hyperfiltration injury. We evaluated our transplants from the small donors focusing on the complications.
Methods: We retrospectively studied 31 cases of en-bloc kidney transplantation from pediatrics weighing less than 5kg between 2014-2019. All allografts were preserved by static cold storage. Induction immunosuppression consisted of thymoglobulin+methylprednisolone, and maintenance of tacrolimus+mycophenelate mofetil+prednisone. 19/31 were administered with low molecular weight heparin, while 12/31 had no postoperative anticoagulation. All recipients were followed up for at least 1 year.
Results: 8 recipients (25.8%) including 2 graft venous thrombosis, 4 graft arterial thrombosis, 1 primary non-function, and 1 acute rejection had early graft loss in two weeks after transplant. Graft thrombosis morbidity in the anticoagulation treated group is even higher than the non-anticoagulation group (26.3% vs 8.3%, p>0.05). The remaining 23 recipients had satisfactory renal perfusion and renal function recovery. Their proteinuria (PU) morbidity is 30.4%, 21.7%, 21.7% at 3, 6, 12 months after transplant respectively. And the recipient/donor body weight ratio of PU and non-PU recipients were not significantly different (p>0.05) at these time points. Overall delayed graft function (DGF) morbidity is 39.1% (9/23), in addition the DGF recipients had significantly higher (20.8±9.9 vs 13.3±2.9, p<0.05) recipient/donor body weight ratio than the ones without DGF.
Conclusions: Kidneys from neonatal donors can achieve promising outcomes with proper surgical procedures and perioperative managements. However, there was a learning curve for utilizing these small grafts. Postoperative anticoagulation did not contribute to prevention of graft thrombosis. Higher recipient/donor body weight ratio seemed to be related to higher possibility of DGF but not proteinuria. Future expanded studies are warranted to determine the reliability of our protocol of using such small donors and long-term recipient outcomes.



Donor and Recipient Characteristics	
Donor Wt (kg; median, range)	3.3, 1.3-5.0
Donor Age (d; median, range)	25, 4-120
Recipient Wt (kg; mean ± SD)	46.9±5.6
Recipient Age (yrs; mean ± SD)	27.6±7.0
Recipient/Donor Wt Ratio (mean ± SD)	15.7±3.0

Abstract# 1022

Nutrition, Body Habitus, and Food Insecurity, in Pediatric Kidney Transplant Recipients

A. Wilkerson[1], J. Figueroa[1], C. Kang[1], R. Garro[2], M. Kamel[1], R. P. George[2], *[1]Emory University, Atlanta, GA, [2]Emory University and Children's Healthcare of Atlanta, Atlanta, GA*

Purpose: Appropriate nutrition and physical activity are critical for optimal post-transplant recovery and long term outcomes, especially in pediatric populations. Both malnutrition and obesity are detrimental for transplant recipients and are influenced

by several factors including socioeconomic status and access to healthy food. The purpose of our study was to assess the nutritional status of pediatric kidney transplant recipients, in the context of household income and food access, since there is scant data in the literature about this.

Methods: Data was collected from 79 patients (25 females; 38 White, 26 Black), who were ≥1 year post-transplant with stable, functioning allograft. Nutrition and physical activity were assessed using the validated Family Nutrition and Physical Activity Screening (FNPA) tool. Patients' Body Mass Index (BMI), and Percentage Body Fat (PBF) were measured using Bioelectrical Impedance Analysis (BIA). Family economic status and zip codes were self-reported. Food access was assessed using United States Department of Agriculture (USDA) Food Access Research Atlas. Limited access was defined as the lack of a supermarket within 0.5 mile (urban) and 10 miles (rural), per USDA Economic Research Service food atlas 2020. Wilcoxon rank-sum tests and Chi-square tests were used for comparisons of continuous and categorical data, respectively.

Results: Patients were 8-20 years old (median age: 15), with BMI showing 5%, underweight, 55% normal, 12% overweight and 27% obese. Reported household income (71 patients) showed 49% (n=35) below an annual income of <$50,000, designated as low income. BMI (p=0.004) and PBF (p=0.02) were higher in patients with low income, compared with high income. Patients in low income group had higher obesity (45% vs. 14%, p=0.028). Overall, 52% (n=41) lived in low food access areas which included 54% with a reported low household income. Of patients who lived in low food access areas 51% (n=19) had elevated BMI.

Conclusions: Higher BMI, has traditionally been associated with comorbidities and sub-optimal post-transplant outcomes. Patients of lower economic status have less access, especially to healthy or fresh foods and are more at risk for higher BMI. The nuances of household income and food access should be taken into consideration when providing nutritional recommendations and education should be tailored for resources available to our pediatric kidney transplant patients and their families. It is critical to partner with community organizations and work for systemic change to mitigate these challenges.

Abstract# 1023

Use of Donor-Derived Cell-Free DNA in Children with Kidney Transplantation: A Pilot Study

E. Winnicki, J. Brennan, M. McEnhill, P. Brakeman, E. Ku, *UCSF, San Francisco, CA*

Purpose: Use of a blood test to detect donor-derived cell-free DNA (dd-cfDNA) levels has been shown to predict rejection in adults with kidney transplants. If dd-cfDNA levels perform similarly in children, use of this biomarker for monitoring pediatric recipients could lead to earlier detection of rejection and potentially reduce the need for biopsy. We aim to determine whether dd-cfDNA is a useful marker of rejection in children by designing a cohort study with serial assessments of dd-cfDNA levels after kidney transplantation. The primary objective of this phase of the study was to assess feasibility of participant recruitment and ascertainment of dd-cfDNA levels as well as parent/patient perspectives on its potential application in routine care.

Methods: This is a single-center prospective study of children treated with kidney transplant. At enrollment, participants (if >8 years) or their parents (if </=8 years) were asked to rate how concerned they were about having blood drawn or undergoing kidney biopsy (with 1 being least concerned and 10 being most concerned.) Donor-derived-cfDNA levels were obtained using AlloSure. We defined baseline dd-cfDNA level as the first level obtained in participants >/=2 months post-transplant with stable creatinine. Baseline dd-cfDNA levels were compared between children <13 vs. >/=13 years using Wilcoxon Rank-Sum test.

Results: Of 29 patients approached for participation, 27 (93%) consented to enroll. Median (Q1, Q3) age at entry was 13 (5, 16) years, 56% were male, 37% were non-Hispanic white race, and the primary cause of ESKD was congenital anomalies of the kidney and urinary tract (48%). Participants or their parents (for younger children) were least concerned about blood draws, with a median (Q1,Q3) rating of 1 (1,1). Median (Q1, Q3) rating for level of concern of undergoing kidney biopsy was 3 (1,5). Of 25 participants with stable creatinine, baseline dd-cfDNA levels were ascertained in 24 (96%) at a median (Q1,Q3) of 23.6 (5.0, 69.0) months post-transplant; one sample was hemolyzed. Median (Q1,Q3) baseline dd-cfDNA level was 0.29% (0.19,0.48) in the overall cohort. Levels were not significantly different for younger versus older children (median 0.36% vs. 0.21%, p=0.11, Figure).

Conclusions: Recruitment of participants and ascertainment of dd-cfDNA levels is feasible in this prospective cohort study. Baseline dd-cfDNA are similar in younger children compared to adolescents to date. This ongoing study will follow dd-cfDNA levels and aims to determine whether dd-cfDNA levels will discriminate risk of rejection.

Abstract# LB 80

Food Insecurity and Impact on Transplant Outcomes in Pediatric Kidney Transplant Recipients

A. Moin, P. Verghese, R. Engen, D. Matossian, *Pediatric Nephrology, Lurie Children's Hospital, chicago, IL*

Purpose: Food insecurity (FI), defined as inconsistent access to food or worry over shortage of food that prevents an active and healthy life, has not been studied in pediatric kidney transplant (pedsKTx) recipients. The COVID-19 pandemic increased prevalence of FI in children from 17.4% to 19.9% incentivizing this single-center retrospective cohort study in the largest pediatric hospital in Illinois, to assess for FI prevalence in pedsKTx and association with transplant outcomes.

Methods: A 2-question survey was administered to all pediatric kidney recipients that attended the kidney transplant clinic in person or via telemedicine for the month of November 2020. All families were asked if they were ever worried that food would run out or if food ever ran out over the past year. Sociodemographic and clinical data from December 2019 to November 2020 were collected using electronic health records.

Results: FI was identified in 12/45(26.7%) pedsKTx patients. Hispanic ethnicity (RR 3.75 (95th%ile CI 1.16-12.04), p= 0.019) was associated with FI. FI patients were more often on Medicaid vs private insurance (75% vs. 54%) and received deceased vs living donations (75 % vs. 69%), although not statistically significant possibly due to small numbers. Age, gender, race, time from transplant, good medication adherence, type of underlying renal disease and presence of hypertension were not significantly associated with FI status. Rejection episodes (25% vs. 9%) and hospital admissions (58.3% vs. 36.4%) were not significantly associated with FI although infectious hospitalizations trended towards significance (25% vs. 3%, p=0.05).

Conclusions: Food insecurity is prevalent in pediatric renal transplant patients. Hispanic patients are more likely to be food insecure. The pandemic effect on magnifying prevalent racial and ethnic disparities in pediatric kidney transplant requires a larger sample size.

Kidney

Kidney Acute Antibody Mediated Rejection

Abstract# 1025

Outcomes of Kidney Transplant Recipients with Antibody-mediated Allograft Rejection: A Retrospective Study

A. Al Jurdi[1], L. Goldfarb[1], M. Lafargue[2], J. Azzi[3], L. V. Riella[1], *[1]Center for Transplantation Sciences, Massachusetts General Hospital, Charlestown, MA, [2]Université de Paris, Paris, France, [3]Transplantation Research Center, Brigham and Women's Hospital, Boston, MA*

Purpose: The optimal regimen for treating acute and chronic antibody-mediated rejection (AMR) in kidney transplant recipients has yet to be established. The purpose of the study was to evaluate the outcomes of kidney transplant recipients with acute and chronic AMR managed with different treatment regimens.

Methods: We conducted a single-center retrospective cohort study of all kidney transplant recipients with biopsy-proven acute or chronic AMR between January 2017 and September 2020. The primary outcome was allograft loss at last follow up. Secondary outcomes included differences in allograft survival between treatment regimens, and changes in estimated glomerular filtration rate (eGFR) and urine protein-creatinine ratio (UPCR) at last follow up.

Results: Fifty-three kidney transplant recipients with AMR were included in the study. Mean age was 51 years, 50% were female and the most common cause of end-stage kidney disease was glomerular disease. 57% received living donor kidney transplants, median number of HLA ABDR mismatches was 4, and 38% had pre-transplant donor-specific antibodies. For induction immunosuppression, 61% received anti-thymocyte globulin, while 35% received basiliximab and 4% alemtuzumab. 35% had acute AMR and 65% had chronic-active AMR. At the time of biopsy, mean (±SD) eGFR was 32±16ml/min/1.73m^2 and UPCR was 3.0±5.6g/g. For treatment, 72% received pulse steroids, 64% received intravenous immunoglobulin, 51% received plasma exchange, 43% received bortezomib and 4% received rituximab. Some patients received more than one of the treatments listed. At a median follow up of 23 months, patient survival was 94% and death-censored allograft survival was 74%; mean (±SD) eGFR was 28±19ml/min/1.73m^2 and UPCR was 0.96±1.4g/g. The risk of allograft loss was higher in patients with UPCR greater than 3g/g at time of biopsy compared to those with UPCR less than 3g/g (relative risk [RR]=4.3, 95% 95% confidence interval [CI]: 1.6-11.6). There was no difference in the risk of allograft loss in patients who received plasmapheresis compared to those who did not (RR=0.97, 95% CI: 0.4-2.4). There was also no significant difference in the risk of allograft loss in patients who received bortezomib compared to those who did not (RR=0.8, 95% CI: 0.3-2.0). The risk of allograft loss was similar in patients with chronic AMR compared to those with acute AMR (RR=1.3, 95% CI: 0.5-3.6).

Conclusions: Proteinuria above 3g/day is associated with increased risk of allograft failure in patients with AMR. Use of plasmapheresis or bortezomib was not associated with lower risk of allograft failure in kidney transplant recipients with AMR. Novel treatment regimens are needed to improve the outcomes of kidney transplant recipients with acute and chronic AMR.

Abstract# 1026

Clinical Validation and Performance of Donor-Derived Cell-Free DNA in Allograft Rejection

S. Anand[1], A. Pai[2], J. S. Bromberg[3], G. Gupta[4], I. Moinuddin[4], T. Alhamad[5], V. Bowers[6], S. Ghosh[7], W. Tian[7], L. Bu[8], E. Stites[9], *[1]Intermountain Medical Center, Murray, UT, [2]University of Texas McGovern Medical School, Houston, TX, [3]University of Maryland School of Medicine, Baltimore, MD, [4]Virginia Commonwealth University, Richmond, VA, [5]Washington University in St. Louis, St. Louis, MO, [6]Tampa General Hospital, Tampa, FL, [7]CareDx, Brisbane, CA, [8]University of Minnesota, Minneapolis, MN, [9]University of Colorado, Aurora, CO*

Purpose: Extensive literature regarding the utility of donor-derived cell-free DNA (dd-cfDNA) shares various thresholds for active rejection (AR) based on differing data sets for both cellular (TCMR) and antibody-mediated allograft rejection (ABMR) after kidney transplant (KT). Our aim was to independently validate the performance of dd-cfDNA in the context of AR, both in "for cause" but also in the context of surveillance biopsies, the latter typically highlighting detection of subclinical rejection.

Methods: Patients from the Assessing dd-cfDNA monitoring insights of renal allograft with longitudinal surveillance (ADMIRAL study; clinicaltrials.gov: NCT04566055219) were analyzed with total of 219 biopsies (Bx) and paired plasma dd-cfDNA (AlloSure®; CareDx) from 196 patients (110 "for cause", 109 "surveillance" Bx). Samples were considered if Bx was performed ≤ 20 days after dd-cfDNA measurement. AR was detected in 107 Bx from 95 patients (65 "for cause", 42 "surveillance") and compared to 112 Bx from 108 patients (45 "for cause", 67 "surveillance") who did not have AR.

Results: 74 episodes of ABMR were detected in 66 Patients (39 "for cause", 35 "surveillance") and 33 TCMR in 30 patients (26 "for cause", 7 "surveillance"). The AUC for AR events = 0.77, AUC for ABMR = 0.80 and TCMR = 0.70 [**FIGURE 1**]. Median level dd-cfDNA with ABMR = 2.1% in "for cause "and 0.91% for "surveillance" Bx [**FIGURE 2**]. Median level dd-cfDNA with TCMR = 0.85% in "for cause" and 0.52% for "surveillance" Bx. Absence of rejection was associated with median dd-cfDNA = 0.39% in "for cause" and 0.23% for "surveillance" Bx procedures.

FIGURE 1.

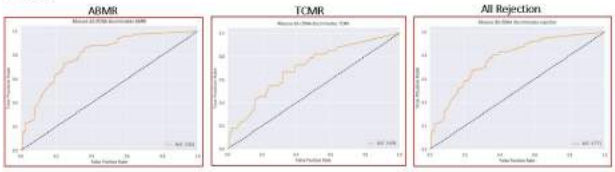

FIGURE 2.

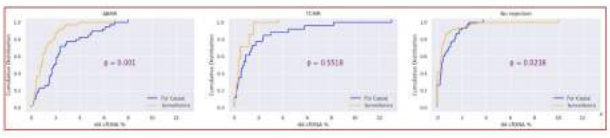

Conclusions: These results independently validate the robust performance characteristics of dd-cfDNA (AlloSure®) as consistent with the published literature ─ for detection of both clinically suspected and *subclinical* allograft rejection. dd-cfDNA has utility in the detection of both TCMR and ABMR with different patterns of elevation. As these are overlapping and difficult to discriminate, further analysis of Δdd-cfDNA from prior baseline may further optimize use of Bx and enhance histological interpretation.

Abstract# 1027

A2 to B Deceased Donor Renal Transplantation Outcome Analysis: Single Center Experience

S. Bindroo, M. Doshi, *Nephrology, University of Michigan, Ann Arbor, MI*

Purpose: Initial experience under kidney allocation system (KAS) implemented in December 2014 showed equivalent outcomes for A2 to B kidney transplantation compared with ABO compatible kidney transplants. Despite the advantages, A2 to B kidney transplantation has been underused and significant knowledge gaps are noted in areas of rejections, infection rate, anti-A titer thresholds post-transplant. The purpose of our study is: 1) To assess AMR rates in A2 to B DDKT and determine association with anti-A IgG titers. 2) To assess graft function, rejection and infection rates (bacterial, viral and fungal).

Methods: We conducted a retrospective chart review of 55 A2 to B DDKT performed at the University of Michigan from January 2015 to September 2020. All patients received Thymoglobulin for induction and were maintained on triple immunosuppression. All patients underwent monitoring of anti-A2 titers and surveillance biopsy at 3-, 6- and 12- months after transplant. Other outcomes included graft function, rejection and infection rates in our cohort at last follow-up.

Results: Our cohort consisted of 55 recipients with mean age of 54(±13) years, 67% males and 29% African Americans. The median follow-up time was 2.5 [0.5-5] years. Ten (15%) developed acute rejection at 3 [1-6] months after transplant. One patient developed hyper-acute rejection due to ABO incompatibility, five developed T cell mediated rejection, and four had antibody mediated rejection. Anti-A titers remained undetectable or less < 1:4 in 54 (98 %) in post-transplant period with no increase in titers at 3-6 month follow up. The patient with hyper-acute rejection in one out of four patients with AMR anti-A titers increased to 1:128, in rest three anti-A titers remained same (1:2) and rejection was due to donor specific antibodies against HLA. Overall, 20% (11/55) mortality was noted, unrelated to graft dysfunction at median follow-up of 1.8 [0.08-4] years. Post-transplant infections (bacterial, viral and fungal) accounted for 41% cases (23/55). Bacterial infections were reported in 16 % (9/55), viral in 25% (14/55) and fungal in 3.6 % (2/55) respectively. BK viremia noted in 20% (11/55) with BK nephropathy in six. The mean (SD) glomerular filtration rate (GFR) mL/min, creatinine mg/dL and urine protein creatinine ratio (UPCR) at three months, one year and at last follow up post-transplant was 49 (14.69), 1.4(0.47), 0.32 (0.55); 54 (14.49), 1.3 (0.43), 0.17(0.20) and 52.8 (14.69), 1.4(0.59), 0.22 (0.27) respectively.

Conclusions: Our study showed no overall increase in AMR due to ABOi in A2 to B DDKT. The rise in anti-A titer was noted in one AMR and rejections were associated with increase in donor specific anti-HLA antibodies. Our study is the first study to assess AMR along with anti-A titers in A2 to B DDKT. More such studies are needed to assess anti-A trajectory with AMR. We also noted high infection and BK viremia rates, attributed to use of Thymoglobulin induction therapy. While A2B transplants have good graft outcomes, infectious complications are more frequent.

Abstract# 1028

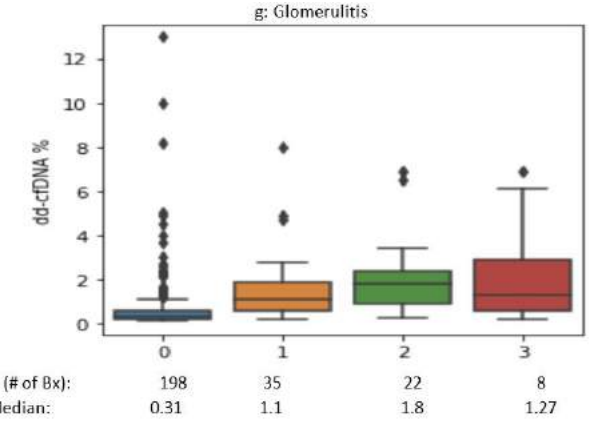
Plasma Donor-Derived Cell-Free DNA Levels Risk-Stratify Kidney Allograft Injury with Isolated Transplant Glomerulitis

L. Bu[1], S. Anand[2], A. Pai[3], J. S. Bromberg[4], G. Gupta[5], I. Moinuddin[5], T. Alhamad[6], V. Bowers[7], S. Ghosh[8], W. Tian[8], E. Stites[9], *[1]University of Minnesota, Minneapolis, MN, [2]Intermountain Medical Center, Murray, UT, [3]University of Texas McGovern Medical School, Houston, TX, [4]University of Maryland School of Medicine, Baltimore, MD, [5]Virginia Commonwealth University, Richmond, VA, [6]Washington University in St. Louis, St. Louis, MO, [7]Tampa General Hospital, Tampa, FL, [8]CareDx, Brisbane, CA, [9]University of Colorado, Aurora, CO*

Purpose: The Banff lesion Glomerulitis (g) characterizes the degree of microvascular glomerular inflammation. Some studies have demonstrated glomerulitis in the absence of C4d in association with donor-specific HLA antibodies (DSA). The clinical significance of *"isolated glomerulitis"* has not been adequately studied in light of heterogenous clinical outcomes and "equivocal" Banff lesion scores. We hypothesized that quantification of molecular inflammation with donor-derived cell-free DNA (dd-cfDNA) may permit risk-stratification of (g).

Methods: 263 KT biopsies with paired dd-cfDNA levels (AlloSure®; CareDx, Inc.) were examined from the Assessing AlloSure dd-cfDNA monitoring insights of renal allograft with longitudinal surveillance (ADMIRAL Study, clinicaltrials.gov: NCT04566055219). Paired biopsies performed ≤ 20 days after the dd-cfDNA level consisted of both "protocol" and "for cause". Pathology reports were centrally interpreted and scored. Correlations with histology lesion and dd-cfDNA levels were performed; high dd-cfDNA was defined as >0.5% based on previous injury analysis for ADMIRAL cohort. Isolated glomerulitis was assessed using Banff 2018 with g(0):no glomerulitis, g(1): segmental or global glomerulitis < 25% glomeruli, g(2):25-75% and g(3): >75% glomeruli affected.

Results: 198 biopsies with no glomerulitis, (g(0), had median dd-cfDNA = 0.31%, while 35 had g(1) median 1.1%, g(2) 1.8% or g(3) 1.27%. Significant differences were observed between normal and active g lesions, but not across spectrum of active g lesions. There were statistically significant differences between g(0) and g(1) [p=1.63e-05] and g(2) [p=4.12e-08]. Despite the sample-size (n=8), the putative trend discordance for the severe g(3) was significant with respect to g(0) [p=0.0183].



Conclusions: Isolated glomerulitis has some correlation with dd-cfDNA which may enhance interpretation compared to Banff criteria alone. Active histological changes may not precisely correlate with graft injury and so considering higher plasma dd-cfDNA levels regardless of the degree of glomerulitis may be beneficial to interpretation.

Abstract# 1029

The Role of Donor-derived Cell-free DNA Testing in Detecting Subclinical Kidney Allograft Rejection

M. Dasari[1], J. Hendele[2], L. Sibulesky[2], N. Leca[3], *[1]Department of Surgery, University of Washington, Seattle, WA, [2]Department of Surgery, Division of Transplant, University of Washington, Seattle, WA, [3]Department of Nephrology, UW Medicine Kidney and Pancreas Transplantation Program, University of Washington, Seattle, WA*

Purpose: Donor-derived cell-free DNA (dd-cfDNA) testing is an emerging method of non-invasive testing for graft rejection in the field of solid-organ transplantation. We describe how dd-cfDNA testing aided in the diagnosis of subclinical rejection in a group of kidney transplant recipients at our institution.

Methods: We conducted a retrospective analysis of 227 patients who underwent renal transplantation at our institution between 2017-2020 and had dd-cfDNA testing within 4 months post-transplant. We analyzed serum creatinine trends post-transplant for all patients, donor serum antigen (DSA) and tissue biopsy results.

Results: 7.9% (18/227) of patients had dd-cfDNA test results that indicated probability of active rejection. 10 of the 18 underwent tissue biopsy. 1 of the patients had an acutely abnormal change in creatinine prompting biopsy; 1 patient had hematuria and proteinuria; the other 8 patients were subclinical with normal or stable creatinine values and biopsy was performed based on abnormal dd-cfDNA test alone. 8 biopsies were consistent with rejection: 4 with antibody-mediated rejection, 2 with cellular rejection, 2 with concern for both types of rejection. Only 1 of the 8 patients had previously detected donor serum antibodies (DSA).

Conclusions: dd-cfDNA testing can help detect rejection in the absence of other markers of abnormal allograft function (detected DSA, abnormal changes in creatinine, clinical symptoms). In our cohort, 8 of 10 patients with abnormal dd-cfDNA results had biopsies that confirmed rejection. Our experience suggests that dd-cfDNA can allow clinicians to detect both cellular and antibody-mediated variants of rejection in otherwise clinically stable patients, suggesting a role for dd-cfDNA in screening for patients who should undergo biopsy.

Abstract# 1030

Donor Derived Cell-free DNA Kinetics Early After Kidney Transplant in Patients with Delayed Graft Function Who Received Kidneys from Donation After Cardiac Death Donors

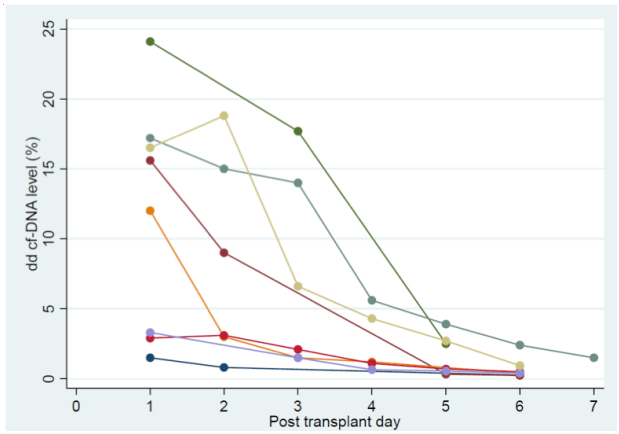
R. Gumber, M. Abuzeineh, C. Mejia, D. Brennan, F. Naqvi, *Division of Nephrology, Johns Hopkins University School of Medicine, Baltimore, MD*

Purpose: Delayed graft function (DGF) may reduce long-term kidney allograft survival due to ischemia-reperfusion injury and rejection. Donor Derived Cell-Free DNA (dd-cfDNA) is proposed to be a non-invasive marker for detection of allograft rejection and injury. Dd-cfDNA are higher in deceased than living donor recipients in the first week after Kidney Transplant (KTxp) and decrease to less than 1.0% in the absence of DGF. This exploratory study describes the kinetics of dd-cfDNA in the immediate post-transplant period in patients with DGF, which has not been studied previously, and determines its' correlation with allograft function.

Methods: Eight deceased-donor KTxp recipients at high risk for DGF (score of 30% or more on Irish Nomogram: *Irish W* et al. AJT,10:2279-2286) were enrolled after signing an informed consent. Blood samples were collected daily for 7 days post-KTxp for dd-cfDNA (AlloSure, CareDx).

Results: Table 1 shows baseline recipient and donor characteristics. All patients had DGF with subsequent recovery of allograft function. Median duration of DGF was 9.5 days (IQR 6.5-21.8). Median nadir serum creatinine (sCr) was 1.4 mg/dL (IQR 0.98-1.8) at last follow up of 1-7 (median 2.5) months post KTxp. The dd-cfDNA kinetics for each patient is shown in Figure 1. Median dd-cfDNA level at day 1 was 14% (IQR 3-17%) and at day 7 was 0.45% (IQR 0.3-1.36%). Duration of DGF showed weak correlation with daily average decline in dd-cfDNA (R^2=0.37), but no correlation with dd-cfDNA level at day 7 (R^2=0.0005). There was no correlation of nadir sCr with daily average decline in dd-cfDNA (R^2=0.03) or dd-cfDNA level at day 7 (R^2=0.001).

Table 1		
	Recipient characteristics	**Donor characteristics**
N	8	7
Median age	59.5 years (IQR 44-62.8)	51 years (IQR 28-58.5)
Race	4 Black, 2 Asian, 2 White	1 Black, 7 White
Sex	3 Female, 5 Male	3 Female, 5 Male
Median time on dialysis	48.5 months (IQR 29.8-71.5)	
DCD		n=7
Median KDPI		67.5% (IQR 40.5-89)



Conclusions: In patients with DGF who received kidneys from DCD donors, dd-cfDNA levels are elevated immediately after KTxp, but decline within the first week to <1.5%. Our data suggests that in these patients, elevated dd-cfDNA of >1.5% (3x the median) and not decreasing 7 days after KTxp warrants further investigation for the cause of persistent elevation which may include rejection, obstruction, recurrent disease etc.

Abstract# 1031

Utility of Donor-Derived Cell Free DNA for Detecting ABMR in Patients With AT1R Antibodies

S. Kant[1], D. Kumar[2], I. Moinuddin[2], T. Alhamad[3], M. Haris[3], J. Gray[4], B. Dale[4], M. Bettinotti[1], D. C. Brennan[1], *[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]VCU, Richmond, VA, [3]Wash Univ, St. Louis, MO, [4]CareDx, Brisbane, CA*

Purpose: The presence of angiotensin II type 1 receptor (AT1R) antibodies is associated with non-HLA active antibody mediated rejection (ABMR). The frequent co-existence of negative donor-specific antibodies (DSAs) and histological features of ABMR with positive AT1R antibodies underlies the need for non-invasive markers of rejection. We investigated the utility of donor derived cell free DNA (dd-cfDNA) in patients with positive AT1R antibodies and ABMR.

Methods: We performed a multicenter retrospective analysis of patients with positive AT1R antibodies who had concomitant dd-cfDNA measurements (AlloSure, CareDx) for surveillance or worsening of allograft function concerning for rejection. These patients also underwent allograft biopsies demonstrating evidence of ABMR with negative DSAs. A positive AT1R test was defined as >10 IU/mL and dd-cfDNA >1%. Statistical analysis included Spearman correlation and Mann-Whitney tests

Results: We identified 16 kidney transplant recipients with histologic evidence of ABMR with negative DSA and positive AT1R antibodies- 6 (38%) were female, 7 (44%) were Caucasian (44%) and 7 (44%) were African American, with a mean

age 43 years at transplant. Thirteen patients (81%) underwent deceased donor kidney transplantation. Primary FSGS was the etiology of kidney disease in the majority of patients.

All patients had elevation of dd-cfDNA >1% prior to allograft biopsy with median levels 2.6% (0.66-7.9%). There was an inverse association between levels of AT1R and dd-cfDNA (r=-0.2, p=0.2),with stronger correlation for dd-cfDNA done for concern for rejection (r=- 0.5, p= 0.12) compared to those done for all purposes. Levels of dd-cfDNA were lower in patients with FSGS as primary disease (p=0.04), in comparison other etiologies of kidney disease.

Dd-cfDNA levels correlated well with Banff grades of rejection (g r=0.3 p=0.12; ptc r=0.4 p=0.05; g+ptc r=0.4 p=0.04, i+t r=0.06, p=0.4), with AT1R levels demonstrating no correlation (Fig 1)

Conclusions: This study suggests that AT1R titers do not reflect severity of ABMR, while dd-cfDNA correlates well with severity grades of the Banff criteria. This study demonstrates that dd-cfDNA could be used for monitoring and detecting rejection in patients with AT1R antibodies.It is imperative to conduct larger studies to validate these findings.

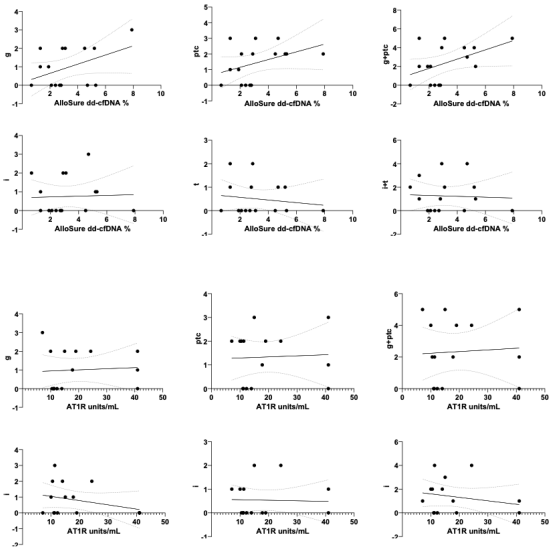

Figure 1. Spearman correlation curves for dd-cfDNA and AT1R levels for various Banff grades of rejection.

Abstract# 1032

Graft Outcomes of Antibody Mediated Rejection without Donor Specific Anti - HLA Antibodies After Kidney Transplantation

H. Ko, S. Min, A. Han, S. Ahn, C. T. Chung, H. Kim, K. Choi, S. Min, H. Kang, J. Ha, *Seoul National University Hospital, Seoul, Korea, Republic of*

Purpose: The aim of this study was to investigate graft outcomes based on the presence of donor-specific anti-HLA antibodies (DSA) and the time of diagnosis in recipients with biopsy proven antibody-mediated rejection (ABMR) after kidney transplantation.

Methods: Data were collected retrospectively for 136 recipients with histological ABMR after kidney transplantation between January 2010 and December 2018 in Seoul National University Hospital. We compared the graft outcome between the group of ABMR without anti-HLA DSA (DSA_{neg}ABMR) and the ABMR with anti-HLA DSA (DSA_{pos}ABMR). In addition, subgroup analysis was performed for the diagnosis time (within 2 weeks or after 2 weeks) of ABMR after kidney transplantation.

Results: Of a total of 136 recipients with biopsy-proven ABMR, 67 (49.3%) were DSA_{pos}ABMR, and 69 (50.7%) were DSA_{neg}ABMR. The mean time to ABMR histologic diagnosis after kidney transplantation was 0.99 ± 1.93 years and 2.17 ± 2.35 years In the DSA_{neg}ABMR group and the DSA_{pos}ABMR group, respectively (p = 0.002). The mean fluorescence intensity (MFI) of DSA_{pos}ABMR was 8276 ± 8130. Although there was no statistically significant difference (p = 0.077), the DSA_{neg}ABMR group tended to have a superior graft survival rate compared to the DSA_{pos}ABMR group. The estimated glomerular filtration rate (eGFR) level was significantly higher in DSA_{neg}ABMR at the time of ABMR diagnosis (DSA_{neg}ABMR, 48.62 ± 30.60 mL/min/1.73m^2; DSA_{pos}ABMR, 38.78 ± 22.99 mL/min/1.73m^2; p = 0.036) and 1 year after diagnosis (DSA_{neg}ABMR, 53.85 ± 23.22 mL/min/1.73m^2; DSA_{pos}ABMR, 42.83 ± 21.29 mL/min/1.73m^2; p = 0.007). In the subgroup analysis of DSA_{neg}ABMR, ABMR diagnosed within 2 weeks after kidney transplantation had a graft survival rate superior to ABMR diagnosed after 2 weeks or more (p = 0.011). The subgroup analysis of DSA_{pos}ABMR also showed a similar pattern (p = 0.016).

Conclusions: Our data demonstrate that DSA_{neg}ABMR diagnosed within 2 weeks after kidney transplantation had a superior graft survival rate.

Abstract# 1033

Combined Impact of Pre-sensitization and Delayed Graft Function on Allograft Rejection in Deceased Donor Kidney Transplantation: A Nationwide Cohort Study

H. Lee[1], Y. Park[1], T. Ban[2], S. Song[3], S. Song[4], J. Yang[5], C. Ahn[5], C. Yang[1], B. Chung[1], *[1]Division of Nephrology, Department of Internal Medicine, Seoul St. Mary's hospital, Seoul, Korea, Republic of, [2]Division of Nephrology, Department of Internal Medicine, Eunpyeong St. Mary's hospital, Seoul, Korea, Republic of, [3]Organ Transplantation Center and Department of Internal Medicine, Pusan National University Hospital, Pusan, Korea, Republic of, [4]Department of Surgery, Ewha Womans University Medical Center, Seoul, Korea, Republic of, [5]Department of Nephrology, Seoul National University Hospital, Seoul, Korea, Republic of*

Purpose: The aim of this study is to investigate whether or not delayed graft function (DGF) and pre-transplant sensitization has a synergistic adverse effect on allograft outcome after deceased donor kidney transplantation (DDKT) using the Korean Organ Transplantation Registry (KOTRY) database, the nationwide prospective cohort.

Methods: The study included 1,370 cases between May 2014 and June 2019. The cases were divided into 4 subgroups according to pre-sensitization and the development of DGF post-transplant (non-pre-sensitized-DGF(-) (n=1100), non-pre-sensitized-DGF(+)(n=133), pre-sensitized-DGF(-) (n=116), and pre-sensitized-DGF(+) (n=21)). We compared the incidence of biopsy-proven allograft rejection (BPAR), change in allograft function, allograft or patient survival, and post-transplant complications across 4 subgroups.

Results: The incidence of overall BPAR and acute antibody-mediated rejection (ABMR) was significantly higher in the pre-sensitized-DGF(+) subgroup than in other 3 subgroups. In addition, multivariable analysis demonstrated that pre-sensitization combined with DGF is an independent risk factor for both overall BPAR and acute ABMR (hazard ratio 9.100, p < 0.001). Moreover, DGF and pre-sensitization showed significant interaction with each other (p for interaction < 0.001). Pre-sensitization combined with DGF did not show significant impact on allograft function, and allograft or patient survival.

Conclusions: In conclusion, pre-sensitization and DGF had a synergistic adverse impact on allograft rejection after DDKT.

Abstract# 1034

The Clinical Significance of Preformed Anti-HLA-DQ Donor-specific Antibodies on Allograft Outcomes in Kidney Transplantation

S. Lee[1], C. Yang[2], B. Chung[2], *[1]Seoul National University Hospital, Seoul, Korea, Republic of, [2]Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of*

Purpose: De-novo anti-HLA-DQ donor-specific antibody (DSA) has been identified as a risk factor for late graft dysfunction and graft loss in kidney transplantation (KT). The impact of preformed anti-HLA-DQ DSA has been discussed, but it has not been established yet. This study aimed to investigate the clinical significance of preformed anti-HLA-DQ DSA on graft outcomes.

Methods: We evaluated 982 recipients who underwent kideny transplantation at Seoul St. Mary's Hospital from January 2010 to December 2018. According to results of DSA using luminex single antigen bead assay, recipients were classified as no DSA group, only DQ group and non-DQ group. Primary outcome was the incidence of biopsy-proven acute antibody-mediated rejection (AMR).

Results: Recipients were classified as no DSA (903 recipients, 91.9 %), only DQ (23 recipients, 2.3 %) and non-DQ (56 recipients, 5.7 %). The only DQ and non-DQ groups had significantly higher the incidence of acute AMR compared to no DSA group ($p < 0.05$, for both). There were no significant differences in the death-censored graft loss rate and mortaliy between groups. In multivariate logistic regression analysis, the presence of preformed anti-HLA DQ DSA or anti-non-HLA DQ, and 4 or more of HLA mismatch number were risk factors associated with acute AMR (anti-HLA DQ DSA: HR 3.23; CI 95 %, $p = 0.040$, anti-non-HLA DQ: HR 6.63; CI 95 %, $p < 0.001$, HLA mismatch number ≥ 4: HR 1.72; CI 95 %, $p = 0.029$, respectively). In Kaplan-Meier analysis for cumulative incidence of acute AMR, the incidences of acute AMR of only DQ and non-DQ groups were significantly higher than no DSA group ($p = 0.010$ and $p < 0.001$, respectively).

Conclusions: Preformed anti-HLA DQ DSA could affect the development of acute rejection, especially acute ABMR, as much as anti-HLA A, B and DR DSA. The identification of preformed anti-HLA DQ DSA can help improve allograft outcomes.

Abstract# 1035

The Clinical Significance of Preformed C1q-binding Donor-specific HLA Antibodies in Kidney Transplantation

S. Lee[1], C. Yang[2], B. Chung[2], *[1]Seoul National University Hospital, Seoul, Korea, Republic of, [2]Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of*

Purpose: Complement activation is one dominant mechanism which cause allograft injury in kidney transplantation (KT). Anti-HLA donor-specific antibodies (DSA) that bind to HLA molecules on graft endothelium are cross-linked by the C1 complex, which initiates the classical complement pathway. De novo complement component 1q-binding donor-specific anti-HLA antibodies (C1q-binding DSAs) are already reported as risk factor associated with acute allograft rejection in KT. This study investigated the clinical significance of preformed C1q-binding DSA for predicting graft outcomes in KT.

Methods: From December 2016 to December 2018, 373 recipients underwent KT at Seoul St. Mary's Hospital. If the results of panel reactive antibodies (PRA) were positive in the pre-transplant examination, DSAs and C1q-binding DSAs were performed using Luminex Single Antigen Bead Assay (SAB) at the same time. Mean fluorescence intensity above 1000 was defined as positive result. Patients with preformed anti-HLA DSA were classified as C1q-positive group and C1q-negative group. Acute rejection was defined as biopsy-proven rejection based upon the Banff classification. Primary outcome was acute antibody-mediated rejection (AMR).

Results: Seventy five of 373 recipients (20.1 %) had preformed anti-HLA DSA, and of them, sixteen recipients (4.3 %) had preformed C1q-binding DSA. C1q-positive group had more positive PRA Class II and DSA class II ($p = 0.036$ and 0.050, respectively). And, DSA Class II MFI in C1q-positive group was significantly higher than in C1q-negative group (13796 (10746.5, 22883.5) vs. 3055.5 (1247.3, 7697.8); $p < 0.001$). In allograft outcomes according to the presence of C1q-binding DSA, the incidence of acute rejection in C1q-positive group is significantly higher than in C1q-negative group, especially acute AMR ($p = 0.037$ and 0.040, respectively). There was no significant difference in death-censored graft loss rate. In univariate logistic regression analysis, the presence of DSA Class II, 5000 or more of DSA MFI, the presence of C1q-binding DSA and C1q-binding DSA Class II were risk factors associated with acute ABR. However, in multivariate analysis, 5000 or more of DSA MFI was the only risk factor associated with acute AMR. In Kaplan-Meier analysis for the cumulative incidence of acute AMR, the incidence of acute AMR in C1q-binding DSA positive group was significantly higher than in C1q-binding DSA negative group ($p = 0.012$).

Conclusions: Preformed C1q-binding DSA may be a risk factor associated with acute AMR. Surveillance, such as protocol allograft biopsy, can help to detect acute AMR early in recipients with preformed C1q-binding DSA.

Abstract# 1036

Comparing Bortezomib Protocol versus IVIG/Rituximab in the Treatment of Antibody Mediated Rejection (AMR) in Kidney Transplantation

V. M. Lowery[1], A. Centeno[1], T. Harrison[1], P. Cabrera[1], A. Mattiazzi[2], *[1]Pharmacy, Jackson Memorial Hospital/Miami Transplant Institute, Miami, FL, [2]Nephrology & Hypertension, Miami Transplant Institute, Jackson Memorial Hospital/Miami Transplant Institute, Miami, FL*

Purpose: To compare outcomes of historical treatment of AMR [PLEX + IVIG + Rituximab] with addition of bortezomib, along with characterizing safety parameters aimed at evaluating the risk versus benefit of additional immunosuppression.

Methods: A single-center retrospective chart review was performed on patients receiving treatment for AMR with either Standard of Care (SOC) [Plasmaphereis (PLEX) x 3-7 sessions + Intravenous Immunoglobulin (IVIG) 2g/kg + Rituximab (RTX) 375 mg/m^2 x 1] or SOC + Bortezomib 1.3 mg/m^2 x 4 doses with IVIG (0.1 g/kg) after PLEX (SOC+B) from 11/2012 to 11/2017. Adult renal transplant recipients (RTR) were included upon first biopsy proven acute AMR. Combined organ transplants, recurrent AMR, AMR > 3 years post-transplant, and those transplanted outside our institution were excluded. Primary outcomes included eGFR over 3, 6, 12, and 24 months, graft and patient survival at 6, 12, and 24 months post treatment. Secondary outcomes included incidence of bacteremia and/or pneumonia within 6 months of treatment, BK or CMV viremia within 6 months, and dose-limiting side effects including thrombocytopenia and leukopenia.

Results: Total of 84 patients were included, SOC (n=23) and SOC+B (n=61). AMR occurred a median of 1.19 years post-transplant. Majority of patients in both groups received maintenance with Tacrolimus/Mycophenolate (MPA) ± steroids. SOC+B group had a trend towards higher median eGFR at time of biopsy (21 vs 36 mL/min per 1.73 m^2; p=0.051), with eGFR at 6 months significantly higher (28 vs 42 mL/min per 1.73 m^2, p=.02). Graft survival at 24 months was higher in SOC+B (35% versus 54%; p=0.02) as well as patient survival at 12 months (87% vs 98%; p=0.03). No difference was observed in incidence of bacteremia, BK or CMV between groups.

	SOC n= 23	SOC+B n= 61	p-value
Tacrolimus/MPA ± steroids	21 (91%)	61 (100%)	
eGFR (mL/min per 1.73 m^2), mo			
3	30	49	0.06
6	28	42	0.02
12	22	48	0.07
24	31	35	0.70
Graft Survival, mo			
6	19 (90%)	51 (84%)	0.91
12	14 (66%)	44 (72%)	0.32
24	8 (35%)	38 (54%)	0.02
Patient Survival, mo			
6	21 (91%)	60 (98%)	0.12
12	20 (87%)	60 (98%)	0.03
24	20 (87%)	57 (97%)	0.09
CMV within 6 mo	2 (9.5%)	4 (7%)	0.70
BK within 6 mo	4 (19%)	3 (5%)	0.10
Bacteremia within 6 mo	1 (5%)	6 (9.8%)	
Pneumonia within 6 mo	0 (0%)	1 (2%)	
Thrombocytopenia	1 (5%)	9 (15%)	0.27
Leukopenia	6 (29%)	13 (21%)	0.46

Conclusions: We observed higher eGFR at 6 months, patient survival at 12 months and graft survival at 24 months with the addition of bortezomib to our SOC in AMR. No significant difference was seen in infectious or safety profile between groups. Further detailed multivariable analysis is needed to confirm these findings.

Abstract# 1037

Membrane versus CentrifugeBased Therapeutic Plasma Exchange to Treat Antibody-Mediated Rejection in Kidney Transplantation

P. Maggiani[1], J. C. Ramirez Valdestino[1], J. H. Cano Cervantes[1], O. D. Díaz Avedaño[1], G. García Castillo[1], M. C. Oseguera Vizcaíno[2], M. A. Covarrubias[2], M. Matías Carmona[1], D. F. Ovando Morga[1], G. Ramirez Ramirez[1], V. D. Lebrija Córdoba[1], S. Hernandez Estrada[1], *[1]Transplantation, Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico, [2]Transplantation, Hospital Civil Fray Antonio Alcalde, Guadalajara, Mexico*

Purpose: Therapeutic plasma exchange (TPE) is either performed using a highly permeable filter with standard multifunctional renal replacement equipment (mTPE) or a centrifugation device (cTPE). Although both techniques are well established in clinical practice, performance of these two modes of TPE was never compared in antibody-mediated rejection (AMR).

Methods: A cohort retrospective study with 27 patients with AMR were analyzed between 2016 to 2020. 14 patients were treated with cTPE and 13 with mTPE. Each patient received 5 sessions of TPE, plus IV immunoglobulin and rituximab. The primary endpoints were a comparison between cTPE and mTPE efficacy in different response markers of AMR. Statistics: Data are presented as median and SD. Comparisons between both techniques and between pre-and post-TPE laboratory marker levels were performed using a paired t test. Differences were considered to be statistically significant if p values were <0.05.

Results: Mean age was 33±9 years, 22 (81%) were living donor recipients. Sensitizing events occurred in 19 (70%). The mean AMR time appearance was 25 months (3 min- 108 max). C4d positivity in 11 (40%) patients. Both treatments were comparable at the end of 3-months post treatment in terms of decrease in creatinine levels (post cTPE 0.4 ±0.7 and post mTPE 0.2 ±0.2 mg/dL, p=0.21), increment in eGFR (post cTPE 6.4 ±16 and post mTPE 6.1 ±10 ml/min, p=0.99), panel-reactive antibody class I reduction percent (post cTPE 2 ±4 and post mTPE 2 ±4 %, p=0.91), and panel-reactive antibody class II (post cTPE 4 ±6 and post mTPE 4 ±4 %, p=0.99), DSA MFI class I reduction percent (post cTPE 41.1% and post mTPE 29.1%, p=0.55), and DSA MFI class II (post cTPE 34.8% and post mTPE 27.3%, p=0.51). (Figure 1).

Conclusions: The improvement between cTPE and mTPE in markers of AMR response were not different between groups.

Abstract# 1038

Donor Derived Cell Free Dna: Teasing Out the Optimal Threshold for Antibody Mediated Rejection

M. Mattu[1], H. Murad[1], M. Merzkani[1], A. Malone[1], R. Delos Santos[1], M. Wang[2], B. Wang[2], S. Chang[2], T. Alhamad[1], *[1]Department of Medicine, Washington University in St Louis, St Louis, MO, [2]Washington University in St Louis, St Louis, MO*

Purpose: Donor-derived cell-free DNA (dd-cfDNA) assay is a putative noninvasive marker for renal allograft rejection and other etiologies of injury such as BK nephropathy. The assay reports donor-derived cell-free DNA as a percentage of total cell-free DNA in the recipient's blood. With it's high negative predictive value (NPV), it serves as a useful rule-out test particularly for antibody mediated rejection (AMR). While most clinicians use 1% as the diagnostic threshold for predicting AMR, our study has tried to elucidate if a lower threshold would be more clinically useful.

Methods: We prospectively collected the dd-cfDNA levels in 63 patients that had a "for cause" renal transplant biopsy planned. These dd-cfDNA values were obtained within 4 weeks of a biopsy. We tested the association of AMR with dd-cfDNA thresholds of 0.5%, 0.75% and 1% and compared them to biopsies with no rejection.

Results: A total of 63 cases were included, of which 21 had AMR, 9 had acute cellular rejection and 33 had no rejection. When comparing the patients with AMR with no rejection, we found that the NPV was 0.75, 0.78 and 0.80, respectively for 1%, 0.75% and 0.5% dd-cfDNA thresholds. The positive predictive value was 0.66, 0.67 and 0.57 respectively. Concurrently the sensitivity was 0.57, 0.66 and 0.76 respectively, while the specificity was 0.8, 0.78 and 0.63 respectively (fig 1).

Conclusions: Our results suggest that a lower dd-cfDNA threshold of 0.75% had a similar PPV and higher NPV than a threshold of 1%. This dd-cfDNA cut off could be a more reliable noninvasive rule-out test for AMR, which will be particularly useful in high-risk renal biopsy candidates. Larger prospective studies are needed to further validate lower dd-cfDNA cutoffs for rejection.

Figure 1

Statistic	Threshold		
	1%	0.75%	0.50%
Sensitivity	57.14%	66.67%	76.19%
Specificity	81.82%	78.79%	63.64%
Positive Predictive Value	66.67%	66.67%	57.14%
Negative Predictive Value	75.00%	78.79%	80.77%

Abstract# 1039

De Novo Membranous Nephropathy Associated with Antibody-mediated Rejection in Renal Transplant Recipients

M. V. Sousa[1], L. G. Fernandes[2], L. L. de Freitas[3], R. L. Zollner[2], M. Mazzali[1], *[1]Internal Medicine - Division of Nephrology, University of Campinas, Campinas, Brazil, [2]Internal Medicine, University of Campinas, Campinas, Brazil, [3]Pathology, University of Campinas, Campinas, Brazil*

Purpose: Membranous nephropathy (MN) is a rare autoimmune disease, with the potential to develop a persistent nephrotic syndrome and end-stage chronic renal disease in some patients, with a recurrence rate after transplant ranging from 30 to 40%. We report a case series of four kidney transplant recipients with biopsy-proven antibody-mediated rejection associated to histological findings compatible with membranous nephropathy. We reviewed the published literature on *de novo* MN associated with AMR and its treatment.

Methods: Single-center retrospective cohort of kidney transplant recipients with donor-specific anti-HLA antibodies and biopsy-proven antibody-mediated rejection, with histological findings compatible with membranous nephropathy. We performed a literature review through a PubMed search using the terms "membranous nephropathy", "antibody-mediated rejection", "DSA", "anti-HLA antibodies". We selected case reports, systematic reviews, clinical trials, multicenter studies, and meta-analysis with cases of membranous nephropathy associated to antibody-mediated rejection.

Results: The time post-transplant to this occurrence varied from 10 to 92 months. Two cases developed class II de novo anti-DQ DSA, and the others presented class I DSA. The patients with longer kidney transplantation presented more intense microvascular inflammation and histological findings of chronic injury, possibly due to subclinical immunological injury. In all these cases, we observed typical histological characteristics of membranous nephropathy, with subepithelial deposits with spikes. One patient did not receive AMR treatment due to infectious events. In other cases, it was administered intravenous immunoglobulin 2g/kg. Only one patient that developed class I DSA received plasmapheresis treatment. We observed one death due to infectious events and one graft failure in our sample. The other two patients remain with functioning grafts and using antiproteinuric drugs. DSA remains detectable in these cases, with routine solid-phase DSA test control every six months.

Conclusions: Different from primary MN, where anti-PLA2R and IgG4 are usually detected, *de novo* MN might represent a form of immune response triggered by exposure of hidden antigens, probably different from those antigens observed in idiopathic MN, and IgG1 staining seems to be dominant. In the reported case, we observed *de novo* anti-DQ antibodies and C4d deposits in the graft. Probably, these antigens elicited immune response, which can lead to damage of podocytes and release of cytoplasmic- or membrane-associated podocytes proteins, with production of antibodies and immunocomplex and its deposition in the subepithelial area.

Abstract# 1040

Treatment and Outcomes of Kidney Transplant Recipients with C4d Negative Antibody Mediated Rejection

M. Walsh, L. Lineberger, M. Brokhof, N. Kenyon, N. Alvey, *Rush University Medical Center, Chicago, IL*

Purpose: The purpose of this study is to describe and evaluate treatment practices and patient outcomes for kidney transplant recipients with presence of C4d negative antibody mediated rejection (AMR) on kidney biopsy.

Methods: This was a single center, retrospective cohort study of kidney transplant recipients. Patients were included in the study if they had a kidney biopsy performed between January 1, 2016 and November 30, 2019 that showed presence of C4d negative AMR. Patients who received treatment for C4d negative AMR had data collected at months 6 and 12 after the completion of treatment. Patients who did not receive treatment for C4d negative AMR had data collected at months 6 and 12 after their biopsy.

Results: Ninety patients were screened for inclusion in this study. Sixty patients who were identified to have C4d negative AMR on kidney biopsy during the specified time period were included. Overall, 46 patients received treatment for C4d negative AMR while 14 did not receive treatment. There were no significant differences in baseline characteristics observed between groups. Treatment for C4d negative AMR consisted of weekly infusions of intravenous immunoglobulin (IVIG) for 31 patients (67.4%), plasma exchange followed by IVIG for 14 patients (30.4%) and plasma exchange followed by IVIG with 1 dose of rituximab for 1 patient (2.2%). When comparing those who received treatment and those who did not, there was not a significant difference in graft survival at month 6 (95.7% vs. 85.7%, p=0.23) or 12 (89.1% vs. 71.4%, p=0.19). In patients with a functioning graft, median change in serum creatinine was not statistically different at month 12 when comparing those who received treatment to those who did not (0.47 mg/dL vs. 0.31 mg/dL, p=0.76).

Conclusions: This study describes treatment practices and patient outcomes of a cohort of kidney transplant recipients at our center who had C4d negative AMR on kidney biopsy. Majority of the patients in this study were treated with either weekly IVIG infusions or plasma exchange in combination with IVIG. Data from this cohort did not reveal a significant difference in change in serum creatinine or graft survival at 12 months for patients who received treatment for C4d negative AMR compared to those who did not.

Abstract# 1041

Use of Donor-Derived Cell-Free DNA for Assessment of Allograft Rejection After Change in Maintenance Immunosuppression Regimens in the First Year Post Kidney Transplant

M. Walsh, V. Peev, L. Lineberger, M. Brokhof, N. Kenyon, N. Alvey, *Rush University Medical Center, Chicago, IL*

Purpose: The purpose of this study was to investigate whether the use of donor-derived cell-free DNA (dd-cfDNA) is an effective screening tool for allograft rejection in kidney transplant recipients who underwent a change in their immunosuppression regimens within the first year post-transplant.

Methods: This was a single center, retrospective cohort study of kidney transplant recipients. Patients were included in the study if they received a kidney transplant between May 1, 2018 and July 31, 2020, had at least 2 dd-cfDNA results and had a change in their maintenance immunosuppression within 12 months post-transplant. Patients were identified as having a change in their maintenance immunosuppression regimen if it was different from our center's standard therapy including tacrolimus, mycophenolate and prednisone within the first 12 months post-transplant.

Results: Sixty-three patients were screened for inclusion in this study. Thirteen patients were identified to have a change in their maintenance immunosuppression within the 12 months following kidney transplantation, 4 of which did not have baseline dd-cfDNA measurements prior to the change in immunosuppression and therefore were excluded. Of the remaining 9 patients, 4 did not have an increase in dd-cfDNA values or a biopsy performed after changes in immunosuppression. Two patients had biopsies performed following changes in immunosuppression without an increase in baseline dd-cfDNA. Both biopsies were negative for acute cellular and antibody mediated rejection. The remaining 3 patients were noted to have an increase in dd-cfDNA measurements after a change in maintenance immunosuppression and proceeding biopsy proven acute rejection.

Conclusions: This study highlights a novel attempt to utilize dd-cfDNA to predict rejection in kidney transplant patients who undergo a change in maintenance immunosuppression regimens within the first 12 months following transplant. In order to fully assess the clinical application of dd-cfDNA in this setting, a larger cohort of patients should be evaluated.

Abstract# LB 76

Detection of Rejection in Kidney Transplant Patients Using an Algorithm That Combines Donor Fraction and Absolute Donor-derived Cell-free DNA

S. Bunnapradist[1], E. Ahmed[2], M. Maninder[2], Z. P. Demko[2], P. R. Billings[2], H. Tabriziani[2], P. Gauthier[3], *[1]David Geffen Sch of Med @ UCLA, Los Angeles, CA, [2]Natera, Inc., San Carlos, CA, [3]Natera, Inc., Los Angeles, CA*

Purpose: Donor-derived cell-free DNA (dd-cfDNA) in the plasma of renal allograft patients is a clinically validated biomarker for allograft injury and rejection. Several dd-cfDNA assays have shown that >1% dd-cfDNA is associated with a high risk for active rejection (AR). Additional studies have shown the advantage of measuring absolute dd-cfDNA concentration to avoid the variability that dd-cfDNA fraction encounters due to the host-derived cfDNA component. Here we present initial results from a new algorithm that combines both dd-cfDNA donor fraction and absolute dd-cfDNA concentration in the plasma and the results were compared with our previous algorithm.

Methods: For this proof-of-concept study, we collected 241 plasma samples from 226 transplant patients. Our cohorts included both related and unrelated donors. Maintaining the 1% dd-cfDNA fraction cut-off, a set of plasma samples (n=200) were used for training the algorithm to set the optimal threshold for absolute dd-cfDNA cut-off (6.9 AU). Samples that exceeded either the 1% dd-cfDNA fraction or the new absolute dd-cfDNA threshold were considered high risk for rejection. The performance of the updated algorithm was further evaluated on the test cohort (n=41), and the results were compared to the previous algorithm that used the 1% dd-cfDNA fraction threshold alone. Biopsy samples were defined as: a) AR, with TCMR and/or ABMR rejection, and b) clinically stable; five patients had TCMR (2xIA, 2xIB, 1xIIB), one had ABMR and two had mixed rejection.

Results: The updated algorithm demonstrated improved performance, with an observed sensitivity of 8/8 (100%), as compared to the previous algorithm with a 1% dd-cfDNA threshold, 6/8 (75%), without compromising the specificity (91%; 30/33).
Conclusions: Host-derived cfDNA can be influenced by a number of physiological and pathological factors, which can therefore affect the reported dd-cfDNA fraction and potentially decrease test accuracy. Thus, an algorithm that incorporates absolute dd-cfDNA concentration to dd-cfDNA fraction is clinically meaningful as it increases sensitivity in detecting rejection in renal allograft patients without affecting the specificity. Future work to further optimize and validate this two-dimensional dd-cfDNA assay is currently ongoing.

Kidney

Kidney Chronic Antibody Mediated Rejection

Abstract# 1042

The Summarized Assessment of Endothelin a Receptors Expression in Renal Transplant Compartments is Associated with Antibody Mediated Rejection

M. Banasik[1], K. Nowanska[1], P. Donizy[2], K. Koscielska-Kasprzak[3], S. Zmonarski[1], M. Kuriata-Kordek[1], A. Tukiendorf[4], A. Hałoń[2], D. Janczak[5], M. Krajewska[1], *[1]Department of Nephrology and Transplantation Medicine, Wroclaw Medical University, Wroclaw, Poland, [2]Department of Pathomorphology and Oncological Cytology, Wroclaw Medical University, Wroclaw, Poland, [3]Research laboratory, Wroclaw Medical University, Wroclaw Medical University, Wroclaw, Poland, [4]Department of Public Health, Wroclaw Medical University, Wroclaw, Poland, [5]Department of General, Vascular and Transplant Surgery, Wroclaw Medical University, Wroclaw, Poland*
Purpose: The presence of non-HLA anti-endothelin A receptor antibodies may be important in transplant injury but the expression of the endothelin A receptor (ETA receptor) in renal compartments has not been described yet. We assessed the presence and relevance of the ETA receptor in renal transplant biopsy for cause. The aim of our study was to evaluate the expression of ETA receptor in patients who had a transplant biopsy due to the deterioration of function.
Methods: Expression of ETA receptors was analyzed in renal transplant biopsies using immunohistochemical method. Microscopic assessment of ETA receptors expression (rabbit polyclonal antibody, dilution: 1:100, catalog number: G094 (P25101); Assay Biotechnology Company, USA) was performed on 4 µm-thick paraffin sections, which were fitted on silanized slides (DAKO, Denmark). ETA receptors expression was analyzed in four compartments of renal transplant biopsies: glomeruli, vessels, tubular epithelium and interstitium. The assessment was presented using three-step scale (0: lack of expression, 1: mild to moderate immunoreactivity, 2: high expression). The results of each compartment for single biopsy were summarized and assessed in context of antibody mediated rejection.
Results: Results: We analyzed 154 patients who had a renal allograft biopsy after renal transplantation. We noticed that patients with antibody mediated rejection had significantly higher summarized expression of ETA receptors 3,28 ± 1,56 in comparison to patients who had biopsy for other reason 1,47 ± 1,35. ($p<0.000001$).
Conclusions: The expression of endothelin A receptors in renal transplant compartments may be associated with antibody mediated rejection. The positive ETA receptor staining might be an important feature in the diagnosis of damage in progress of antibody mediated rejection. The identification of an injury with ETA receptor during rejection may help to the development of new treatment strategies to improve transplant survival.

Abstract# 1043

Higher Calcineurin Inhibitor Levels Associate with Graft Outcomes in Kidney Recipients with De Novo Donor-specific Antibodies of Either Hla Class I or II

M. Béland, S. De Serres, *Nephrology, CHU de Québec- Université Laval, Québec, QC, Canada*
Purpose: The development of de novo anti-HLA donor specific antibodies (dnDSA) is associated with poorer outcomes in kidney transplant recipients. We and other previously reported that calcineurin inhibitor blood levels following dnDSA is an independent predictor of graft loss in small cohorts of patients. Whether or not this observation applies to both HLA classes of dnDSA (I and II) is undetermined.
Methods: We analyzed a cohort of 966 unsensitized patients transplanted between February 2001 and September 2017, for whom anti-HLA antibody screening was performed at 0, 1, 3, 6, 12 months and then annually post-transplant as part of their routine surveillance protocol. dnDSA were detected by flow PRA and identified by Luminex. The endpoint used was a composite of doubling of serum creatinine or graft loss. Analysis was conducted using univariable and multivariable proportional hazards models. Mean tacrolimus post transplant was used as a linear predictor and as a categorical predictor (tertiles).
Results: During the screening period, 58/966 (6.0 %) patients developed dnDSA; 18 (31%) to HLA class I only, 31 (53%) to HLA class II only, and 9 (16%) to both HLA classes. Among these, 25 patients experienced the composite outcome. The event occurred at a median of 15 months (25th-75th percentiles 5-29 months) post DSA detection. Cox modeling revealed that the risk of the composite endpoint decreased with higher mean tacrolimus levels following dnDSA detection (HR 0.83, 95% CI 0.71-0.97, p=0.02). The association remained significant following adjustment for age, sex, time post transplant and serum creatinine level (adjusted HR 0.64, 95% CI 0.50-0.83, $p<0.01$). The relationship was also consistent when restricted to patients with class I anti-HLA dnDSA (adjusted HR 0.57, $p<0.01$; n=27) or with class II dnDSA (adjusted HR 0.63, $p<0.01$; n=40). Analysis of tacrolimus levels by tertiles generated cut-offs at 5.6 and 6.8 ng/ml. Modelling using these tertiles suggested that, compared to mean levels of 6.8 ng/ml, levels <5.6 ng/ml was a strong predictor of the composite endpoint (HR 4.3; 95% CI 1.2-16.3, p=0.03; adjusted HR 19.4 95% CI 2.7-134.9, $p<0.01$). This effect was consistent for each anti-HLA class (class I adjusted HR 28.9, p=0.02; class II adjusted HR 35.7, $p<0.01$).
Conclusions: These data validate previous observation about a relationship between tacrolimus levels and graft outcome post dnDSA detection. It further suggests that tacrolimus levels below 5.6 ng/ml are associated with worse outcome in kidney recipients with dnDSA of both HLA class I and class II.

Abstract# 1044

Non-HLA Antibodies and Eplet Mismatches in Cases with Histological Picture of Antibody-Mediated Rejection with and without HLA Donor-Specific Antibodies

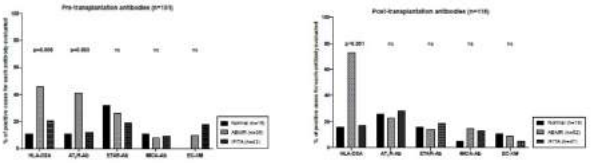
M. Crespo[1], L. Llinás[2], D. Redondo[2], C. Butler[3], J. Gimeno[4], M. Pérez-Sáez[2], A. Buxeda[2], C. Arias[2], M. Folgueiras[2], S. Sanz[2], N. Valenzuela[3], E. E. Reed[3], J. Pascual[2], *[1]Nephrology and Kidney Transplantation, Hospital del Mar, Barcelona, Spain, [2]Nephrology, Hospital del Mar, Barcelona, Spain, [3]UCLA Immunogenetics Center, UCLA, Los Angeles, CA, [4]Pathology, Hospital del Mar, Barcelona, Spain*

Purpose: Correlation between antibody-mediated rejection (ABMR) and HLA donor-specific antibodies (DSA) is strong but imperfect in kidney transplant (KT) recipients, raising the possibility of other detrimental antibodies contributing to ABMR. The role of non-HLA antibodies on outcomes is not well known.

Methods: We retrospectively assessed KT biopsies scored according to Banff'15 classification. Pre- and post-KT serum samples were checked for HLA and non-HLA antibodies (MICA-Ab, angiotensin II type 1 receptor (AT_1R)-Ab, endothelin-1 type A receptor (ETAR)-Ab and crossmatches with primary aortic endothelial cells (EC-XM)). We also analyzed HLA epitope mismatches between donors and recipients.

Results: One-hundred eighteen patients with normal (n=19), ABMR histology (n=52) or IFTA (n=47) in their biopsy were studied. Graft survival was worse in ABMR patients (p=0.003). Pre-KT HLA-DSA were more frequent in ABMR cases (p=0.006). At biopsy, 73% ABMR patients had HLA-DSA (p<0.001). Pre-KT AT_1R-Ab were more frequent in ABMR compared with IFTA and normal cases (p=0.003), without differences in other non-HLA antibodies. Both total class II and DRB1 epitope mismatches were associated with ABMR-DSA$^+$. Fourteen patients with histological ABMR (27%) had no detectable HLA-DSA post-KT and only 3 had non-HLA Ab. However, they showed similar biopsy changes and graft survival compared with ABMR-DSA$^+$. Pre- or post-KT non-HLA antibodies other than AT_1R-Ab were detected only in a small subset of ABMR ($graphic_). Multivariate analysis showed that both pre-KT HLA-DSA and AT_1R-Ab (DSA: OR: 3.39 [1.20-9.59], p=0.021; AT_1R-Ab: OR: 5.31 [1.75-16.10], p=0.003) were strong independent predictors of ABMR-DSA$^+$.

Conclusions: Despite highly prevalent HLA-DSA before and after transplantation in KT with histological ABMR, 27% of cases did not show circulating HLA-DSA. Pre-KT AT_1R-Ab associated with ABMR-DSA$^+$, but not MICA-Ab, ETAR-Ab or EC-XM$^+$. Epitope mismatch predicted both de novo appearance of DRB-DSA and ABMR-DSA$^+$. Detection of pre-KT HLA-DSA and/or AT_1R-Ab, together with HLA epitope mismatch assessment, are valuable tools for better DSA and ABMR prediction in KT patients.



Graphic. Pre and post-KT HLA and non-HLA antibodies in KT recipients with normal, ABMR or IFTA biopsies.

Abstract# 1045

Treatment of Refractory Chronic Active Antibody-Mediated Rejection: Improvement in Histopathology are Delayed Compared to the Reduction in Donor Specific Antibodies

K. R. Degner[1], S. Parajuli[1], F. Aziz[1], N. Garg[1], M. Mohamed[1], D. A. Mandelbrot[1], S. E. Panzer[1], L. Hidalgo[1], N. A. Wilson[1], S. R. Reese[1], K. Van Hyfte[1], W. Zhong[1], P. Nickerson[2], A. Djamali[1], *[1]University of Wisconsin, Madison, WI, [2]University of Manitoba, Winnipeg, MB, Canada*

Purpose: There are limited options for the treatment and management of refractory chronic active antibody-mediated rejection (cABMR) after kidney transplantation. Longitudinal histologic data in patients with refractory cABMR are also lacking. We hypothesized that clinical and histologic evidence of a treatment response may require longer than 3 months, our institutions standard follow up time for patients with rejection, in patients with refractory cABMR.

Methods: Kidney transplant recipients (n=8) with refractory cABMR, defined as persistent rejection despite standard treatment, underwent serial biopsies at diagnosis (index biopsy), 3, 6, and 12 months. Banff 2017 pathology, donor-specific antibodies (DSA), and serum creatinine (SCr), blood urea nitrogen (BUN), estimated glomerular filtration rate (eGFR) and urine protein creatinine ratio (UPC) were assessed at each biopsy. Treatment of rejection included pulse steroids, IVIG, and rituximab.

Results: Participants were primarily white men (88%) at an average age of 40±14.5. Index biopsy was performed an average of 4.4±3.7 years after transplant. Index biopsies were performed primarily for changes in DSA, either rising DSA or development of de novo DSA (63%). One patient lost their allograft during the 12 month follow up period due to ongoing rejection. There was a significant decline in total (6,093±5,424 vs. 2,731±4,172, p=0.04) and Class II DSA (5,845±5,366 vs. 2,731±4,172, p=0.04) between index biopsy and 3 months after treatment. In parallel, there was a decline in C4d staining at 3 months post treatment compared to index biopsy (1.6±1.5 vs. 0.4±1.1, p=0.03). Sum microvascular inflammation (*mvi*) decreased significantly at 12 months, but not sooner (3.7±1.5 vs. 2.3±1.1, p=0.05). Chronic allograft pathology (ct, ci, cv, cg scores) and kidney function in patients with a functioning allograft were stable over the course of the study period.

Conclusions: In patients with refractory cABMR, the decline in DSA precedes improvements in allograft inflammation, suggesting that benefits from therapy may not become evident upon repeat biopsy for at least one year. Larger studies of patients with refractory cABMR are needed to expand upon these observations.

Abstract# 1046

Psmp is Discriminative for Chronic Active Antibody-Mediated Rejection and Predicts Graft Risk After Kidney Transplantation

Y. Fu, P. Zhan, *Tianjin First Central Hospital, Tianjin, China*

Purpose: Chronic active antibody-mediated rejection (c-aABMR) is an intermediate process in the development of chronic antibody-mediated rejection (c-ABMR), a key problem in the long-term failure of kidney graft. PC3-secreted microprotein (PSMP), a new chemotactic cytokine recruiting macrophages, enhances fibrosis progression. However, the relationship between PSMP and chronic active antibody-mediated rejection (c-aABMR) in kidney transplantation need to be further explored. This study was to investigate the role PSMP playing on the progression of c-aABMR and c-ABMR.

Methods: In this study, a total of 29 kidney transplant recipients were included and classified into chronic active antibody-mediated rejection (c-aABMR) group (n=14), chronic antibody-mediated rejection (c-ABMR) group (n=5) and normal function group (n=10) according to their allograft biopsy pathology diagnosis. Patients demographics, kidney allograft biopsy sample fibrosis stained with HE and masson, immunohistochemistry staining of PSMP and CD68, PSMP gene-expression quantitated by real time RT-PCR and the serum and urine PSMP level were compared between three groups. The serum and urine PSMP expressions were detected by ELISA.

Results: Patients demographics results of three groups were no difference. Compared with normal groups, the allograft survival rate of c-aABMR group was significantly low (58.3% vs. 0%). Pathologic Banff scrores of three groups showed that c-aABMR group had more severe peritubular capillaritis (PTC) and tubulitis inflammation (t). Moreover,there was more fibrosis area and eGFR declined in both c-aABMR and c-ABMR groups, but no difference between the two groups. While CD68 expression was highest in c-aABMR among three groups, which was significantly positive associated with fibrosis grade in c-aABMR. Consistent with the CD68 expression, PSMP expression was significance higher in c-aABMR group than c-ABMR and normal groups. A significant correlation was found between the expression between CD68 and PSMP in c-aABMR, PSMP high expressed grafts had significantly higher t, i, c4d score and more allograft function loss compared to PSMP low expressed grafts. In addition, we found that urinary PSMP may be a candidate molecule marker for c-aABMR. Indeed, urinary PSMP concentration was significantly higher in kidney grafts pathologically diagnosed with c-aABMR than c-ABMR and normal counterparts, while no clear trend in serum. Indeed, urinary PSMP concentration was significantly higher in kidney grafts pathologically diagnosed with c-aABMR than c-ABMR and normal counterparts, while no clear trend in serum.

Conclusions: PSMP level was associated with macrophages infiltrating and fibrosis in c-aABMR which could be a promising biomarker to distinguish and predict risks of c-aABMR allograft lost.

Abstract# 1047

Clazakizumab for the Treatment of Chronic Active Antibody-Mediated Rejection in Kidney Transplant Recipients: Phase 3 IMAGINE Study Design

P. Nickerson[1], G. Böhmig[2], S. Chadban[3], D. Kumar[4], R. B. Mannon[5], T. van Gelder[6], S. Adler[7], E. Chong[7], A. Djamali[8], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]Medical University of Vienna, Vienna, Austria, [3]University of Sydney, Sydney, Australia, [4]University of Toronto, Toronto, ON, Canada, [5]University of Nebraska Medical Center, Omaha, NE, [6]Leiden University Medical Center, Leiden, Netherlands, [7]CSL Behring, King of Prussia, PA, [8]University of Wisconsin, Madison, WI*

Purpose: Chronic active antibody-mediated rejection (CAMR) is a major cause of allograft loss with no approved drugs for its treatment. Currently, off-label regimens recommended by experts based on small clinical trials are used, reflecting the high unmet medical need for effective therapies based on well-controlled trials. Clazakizumab (CLAZA) is a high-affinity, humanized monoclonal antibody that binds IL-6 and blocks inflammation and antibody production. Small Phase 2 studies of CLAZA in kidney transplant recipients with CAMR suggest early modulation of donor-specific antibodies (DSA), stabilization of GFR, and a manageable safety profile. In CAMR, a progressive decline in kidney function is, by definition, on the pathway to graft loss. Here, we report the design of the Phase 3 IMAGINE study (NCT03744910) to evaluate the safety and efficacy of CLAZA for the treatment of CAMR.

Methods: IMAGINE is a multi-center, double-blind trial of 350 kidney transplant recipients with CAMR (Banff cg>0 with human leukocyte antigen DSA) randomized 1:1 to receive CLAZA (12.5 mg subcutaneous once every 4 weeks) or placebo (**Fig**). The event-driven trial design will follow pts for 5 years or until 221 occurrences of graft loss (primary endpoint); defined as return to dialysis, graft nephrectomy, retransplantation, eGFR <15 mL/min/1.73m^2, or death from any cause. A surrogate for graft loss, eGFR slope at 1 year, will be assessed based on prior modelling validation[1]. Secondary endpoints will include measures of PK/PD and PROs.

Results: Recruitment is ongoing across sites in N. America, Europe, Asia, and Australia.

Conclusions: Currently, no treatment has proven effective in CAMR. This pivotal Phase 3 trial includes prognostic biomarker enrichment and uniquely incorporates a surrogate endpoint for graft loss, eGFR slope at 1 year, which may accelerate the approval of a novel therapy for patients at risk of allograft loss.

Abstract# 1048

Clazakizumab (clz, Anti-il-6 Antibody) Treatment Affects Il-6/il-6r Signaling by Increasing Soluble Gp130 (sgp130) in Hla-sensitized Kidney Transplant Patients (hs Ktx Pts) Treated for Chronic Antibody-mediated Rejection (cabmr)

B. Shin, S. Ge, A. Jimenez, N. Ammerman, A. Vo, R. Zhang, S. C. Jordan, M. Toyoda, *Cedars-Sinai Medical Center, Cerritos, CA*

Purpose: IL-6 is a pro-inflammatory cytokine responsible for chronic vascular inflammation and a promising target for cABMR modulation. IL-6/sIL-6R complex initiates more pathogenic trans-signaling pathways via interactions with gp130 expressed on various tissues including allografts, and sgp130 is a selective inhibitor of this pathway. We previously reported the increase of plasma sgp130 level at 6 month post-treatment in HS KTx Pts treated with CLZ, and suggested its beneficial effect on cABMR modulation. Here, we report on sIL-6R and sgp130 levels further monitored until 12 months post-treatment in these CLZ-treated Pts and correlated with other clinical findings.

Methods: Plasma samples obtained pre- and post-CLZ (25mg SQ, monthly) (up to 12 months) from 9 HS KTx- Pts with biopsy proven cABMR were submitted for sgp130 and sIL-6R Luminex assays. IL-6, C-reactive protein (CRP) and DSA levels were also measured.

Results: IL-6 levels significantly increased post- vs. pre-CLZ (1113±300 vs. 17±19pg/ml, p=0.005). Near significant reduction of CRP post-CLZ (1.7±1.5 vs. 0.4±0.1μg/ml, p=0.05) in all Pts indicates that high levels of IL-6 detected post-CLZ were mostly CLZ-bound IL-6, and the IL-6/gp130 signaling was efficiently blocked by CLZ. Sgp130 levels gradually increased post-CLZ (Fig. 1), and reached the levels at 12 months post-CLZ, significantly higher than pre-CLZ levels (230±55 vs. 203±49ng/ml, p=0.03). In contrast, sIL-6R levels did not change post-CLZ (Fig. 2). Reduction of DSA and stable eGFR at 24 months post-CLZ were observed although no significant improvement of Banff score for cABMR was observed yet at 6M post-CLZ.

Conclusions: CLZ affected IL-6/IL-6R/sgp130 biology that may result in a risk for progression of cABMR. Significant increases of sgp130 post-CLZ may reduce trans-signaling, potentially reducing pathogenicity to allografts, which may contribute in part to stabilized eGFR in this patient population. A larger randomized control study is required for confirming this possibility.

Kidney

Kidney Complications: Non-Immune Mediated Late Graft Failure

Abstract# 1049

HLA Allele Association with Recurrent Iga Nephropathy After Kidney Transplantation

O. Alzahabi, M. Merzkani, H. Murad, A. Java, R. Delos Santos, T. Alhamad, A. Malone, *Transplant, Washington University, Saint Louis, MO*

Purpose: IgA nephropathy is one of the most common glomerulonephritis after kidney transplantation. The association of IgA nephropathy recurrence with recipient HLA typing is not well understood.

Methods: In this single-center study we included kidney transplant recipients with IgA Nephropathy native kidney disease from the period of 8/19/1994 to 3/1/2020. Diagnosis of IgA nephropathy was achieved by biopsy done in our center. All biopsies were 'for cause'. Recipient class I and II HLA alleles for were analyzed by using logistic regression and risk for recurrence.

Results: There were a total 238 adults with a diagnosis of IgA nephropathy in native kidneys. The mean age was 44.7 ± 13.2 years old, they were more likely to be male 169 (71%). The most common induction was T-cell depleting agent 216 (90.8%) and there were 128 (53.8%) deceased donors. In this cohort a total of 13 (5.46%) patients had biopsy proven recurrent IgA nephropathy. The recipient HLA alleles associated with increased recurrence were in HLA-CW09 (OR=9.34,p=0.01), HLA-DP105(OR=18.67,p=0.043),HLA-DP108 (OR=40.72,p=0.03); HLA-DR52*5(OR=18.7, p=0.043); HLA-DR53*3(OR=13.45,p=0.02). There was a decrease risk in HLA-B08 (OR=0.28, p=0.046), HLA-DP99 (OR=0.28, p=0.008), HLA-DRW53(OR=0.26,p=0.046). Recipient alleles HLA-A, HLA-BW, HLA-DR, HLA-DRW51 were not associated with IgA recurrence.

Conclusions: IgA nephropathy is one of the most common recurrent glomerulonephritis and in this cohort there is an association with recipient HLA alleles. Multicenter and larger studies with long follow up will required to study IgA nephropathy recurrence.

Abstract# 1050

Risk Factors and Outcome of Transplant Renal Artery Stenosis in Kidney Transplant Recipients - A Nested Case-control Study

D. Choudhary[1], A. Sharma[1], R. Vijayvergiya[2], G. Kasinadhuni[2], D. Kenwar[1], S. Singh[1], *[1]Renal & Pancreas Transplant Surgery, Pgimer Chandigarh, Chandigarh, India, [2]Cardiology, Pgimer Chandigarh, Chandigarh, India*

Purpose: Transplant renal artery stenosis (TRAS) is a treatable cause of renal allograft dysfunction. It presents commonly in the early post-transplant period with variable clinical presentation. The diagnosis is usually made on graft Doppler, yet angiography is required for confirmation. The risk factors associated with TRAS include Cytomegalovirus (CMV) infection, Delayed graft function (DGF), and prolonged cold ischemia time (CIT). However, these risk factors are less frequent in a living donor transplant. The present study aims to identify TRAS's risk factors and outcome in kidney transplant recipients in a dominant living donor program.

Methods: A nested case-control study with study period (2007-2020) December. TRAS group n-23 patients' clinical parameters are compared with age and sex-matched control groups of 92 patients in the same year as a kidney transplant. Parametric and nonparametric univariate and multivariate analysis was done.

Results: TRAS cases (n-23) presented from (15-173) with a mean of 104 days post-transplant with renal allograft dysfunction as the most common presenting features in 65% of cases. The initial diagnosis was made on graft Doppler. 20/23 patients were treated by angioplasty with stenting, and angioplasty alone was done in 3/23 patients with ostial TRAS. The duration of follow-up ranged from 6 months to 13 years. There were no interventional complications, and all recipients showed a significant reduction of Serum Creatinine (sCr) from mean sCr of 2.41 to 1.2 mg/dl. One patient died four years after intervention due to pneumonia. Hepatitis C infection, vascular reconstruction, End to side vascular anastomosis, DGF, and high immediate post-operative tacrolimus levels were independent risk factors for TRAS.

Conclusions: Early endovascular intervention amends the allograft dysfunction with an excellent long-term outcome.

Clinical Parameters			
Parameters Live / Deceased	TRAS (n-23) 19/4	Control (n-92) 80/12	Multivariate -significance
Age	38 (16-60)	38(16-60)	
Treated Hepatitis C	8	10	0.028
Arterial Reconstruction	12	11	0.005
End to side vs. end to end anastomosis	14 vs. 9	28 vs. 67	0.027
High tacrolimus level	15	27	0.005
DGF	3	1	0.010

Abstract# 1051

De Novo Atypical Hemolytic Uremic Syndrome (aHUS) in Kidney Transplant Recipients from the Same Donor: Possible Role of Two Genetic Hits

C. Crane[1], J. Sherbotie[2], S. Anand[3], *[1]University of California at San Diego, San Diego, CA, [2]University of Utah School of Medicine, Salt Lake City, UT, [3]Nephrology Associates of Utah, Salt Lake City, UT*

Purpose: Thrombotic microangiopathy (TMA) is an uncommon and potentially serious complication of kidney transplantation. Atypical hemolytic uremic syndrome (aHUS) is a type of TMA most often occurring as a result of dysregulation in the alternative complement pathway. While aHUS can manifest as recurrent disease following a kidney transplant, de novo post-transplant aHUS is uncommon and poorly understood.

Methods: We describe two cases of de novo aHUS occurring in both kidney transplant recipients from the same deceased donor. Recipient 1 was a 3-year-old male with ESRD due to bilateral dysplastic kidneys. Immediately following transplant, he had slow graft function complicated by severe TMA that resolved following administration of eculizumab. Genetic testing later revealed a variant in membrane-cofactor protein (MCP) thought to have a low likelihood of being related to the development of aHUS. Recipient 2 was a 33-year-old female with a history of ESRD of unknown etiology who also developed TMA in the immediate post-transplant period. A kidney biopsy was consistent with TMA and her condition resolved following administration of eculizumab (figure). A genetic panel for aHUS later revealed a homozygous deletion for complement factor H related proteins, associated with Factor H antibodies and aHUS. However, Factor H antibodies were not detected in the patient. Genetic testing was later obtained from donor tissue, revealing a variant in C3 of debatable significance.

Results: Neither donor nor receipts had evidence of TMA prior to transplantation. The possible explanation and trigger lies in the donor C3 mutation. We conjecture the donor variant C3 is a gain of function mutation which led to pre-donation setup of complement activation in the deceased donor with ischemia. Additionally, comple-

ment activation with surgery as a trigger in the immediate post-transplant period resulted in further allograft C3 expression with increased resistance to Factor H and MCP (due to recipients mutations). The overactive and uninhibited C3 resulted in downstream inflammation and endothelial damage leading to the aHUS phenotype in both recipients. We report for the first time, a two genetic hit scenario leading to de novo aHUS in two separate kidney transplant recipients from same deceased donor.
Conclusions: The case highlights the importance of obtaining genetic tests from deceased donor tissue to evaluate possible mechanisms in cases of de novo genetically mediated disease.

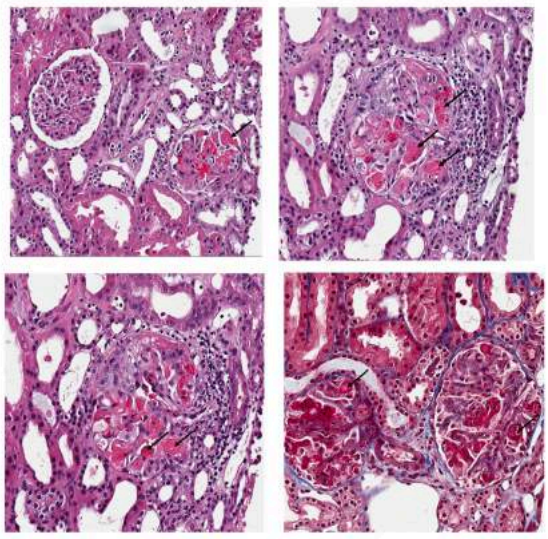

Figure: Biopsy of recipient 2. Upper right, upper left, and lower right demonstrate numerous glomerular capillary microthrombi (arrows), H&E stain. Lower left, trichrome stain.

Abstract# 1052

Kidney Transplantation Outcomes Over Last Six Decades- A Single-center Experience

A. Dinesh[1], S. Jackson[2], A. Matas[1], *[1]University of Minnesota Medical School, Minneapolis, MN, [2]Analytics Consulting Services, M Health Fairview, Minneapolis, MN*

Purpose: During the last 6 decades, the science around kidney transplantation has evolved tremendously resulting in significant improvements in kidney allograft and patient survival. There has been path breaking advancements in the immunosuppressive regimens and the overall care of transplant patients in terms of pre-transplant cardiovascular workup, intraoperative anesthesia, intensive care, prevention, early detection and treatment of rejection and infectious complications. We studied patient and graft survival, and causes of graft loss for primary kidney transplant recipients over 6 decades.
Methods: Between Jan 1, 1960 - Dec 31, 2019, 3298 living donor (LD) and 2292 deceased donor (DD) primary kidney transplants were done (Table 1). The data was stratified by decade and donor type. Actuarial patient and death-censored graft survival determined at 1, 3, 5 and 10 years were compared. Common causes of death with function (DwF) and death-censored graft loss were compared.
Results: Overall patient survival and death-censored graft survival for both LD and DD kidney transplant recipients has improved over the last six decades (Table 1). For each decade, patient and death-censored graft survival for LD recipients are better than for DD recipients. DwF was responsible for ~50% graft loss at each interval (Table 2). For each decade, the 3 major causes of DwF were CVD, infection, and malignancy. "Chronic rejection" although decreasing, has been the most common cause of DD and LD graft loss every decade. Acute rejections and thrombosis have decreased; however, losses due to non-compliance with medications and transplant glomerulopathy has been increasing (Table 2).
Conclusions: The overall effect of improvement in patient care and immunosuppression over the last six decades have resulted in significantly reduced rates of patient and graft loss for both deceased and living donor recipients. DwF and immune-mediated processes remain the most common causes of graft loss. Our data suggests that improving long-term outcomes requires effort to reduce both DwF and death-censored graft loss.

Abstract# 1053

Belatacept Conversion in Proteinuric Renal Transplant Recipients: An Interventional Multi-Center Trial

O. Efe[1], A. Al Jurdi[1], D. Wojciechowski[2], K. Safa[1], H. Gilligan[1], A. Chandraker[3], J. Azzi[3], A. Weins[3], L. V. Riella[1], *[1]Center for Transplantation Sciences, Massachusetts General Hospital, Charlestown, MA, [2]UT Southwestern Medical Center, Dallas, TX, [3]Brigham and Women's Hospital, Boston, MA*

Purpose: Proteinuria develops in about 30% of kidney transplant recipients and is a strong predictor of graft loss. ACEis/ARBs can reduce proteinuria but are frequently associated with worsening hyperkalemia and reduction in estimated glomerular filtration rate (eGFR). Novel therapies are needed to reduce proteinuria and prevent graft loss in transplant recipients. While B7-1 is a well-known co-stimulatory signal that interacts with CD28 on T cells, B7-1 also plays an important role in glomerular proteinuria by promoting disease-associated podocyte migration. Abatacept has been shown to reduce proteinuria in patients with B7-1-positive glomerular disease by stabilizing β1-integrin activation in podocytes. The utility of belatacept in proteinuric kidney transplant (KT) recipients remains to be explored.
Methods: In this phase I multicenter clinical trial, we recruited EBV IgG^+ adult KT recipients at least 6 months post-transplant with an eGFR greater than 30ml/min/1.73m^2, proteinuria greater than 1g/day on CNI-based maintenance immunosuppression and no acute rejection on biopsy in the previous 6 months. Patients were converted from CNI to belatacept. The primary outcome was 25% reduction in proteinuria at 12 months.
Results: Total of 15 KT recipients were included. 87% were male, 20% were black and 73% had received a deceased donor transplant. Diabetic nephropathy was the most common cause of ESKD. At enrollment, mean (±SD) eGFR was 45.2±13 ml/min/1.73m^2, mean urine protein/creatinine ratio was 2.5±0.4 g/g and 67% were on ACEis or ARBs. At 12 months, mean (±SD) eGFR was 43.7±13 ml/min/1.73m^2 and mean proteinuria was 1.7±1.8 g/g. Primary outcome was reached in 53% of the patients. Patients without diabetes mellitus (DM) had a trend towards more reduction in proteinuria, compared to patients with DM (-1.91±2.49 vs 0.1±1.3, mean difference of -1.8 with 95% confidence interval: -0.5 to 4.1). There was no difference between systolic (134±9 vs 129±16 mmHg) and diastolic blood pressures (75±7 vs 73±9 mmHg) at 12 months compared to baseline. During the study period, 13% of patients were newly started on ACEi or ARBs. None of the patients had allograft rejection or developed new donor-specific antibodies. One patient had sudden cardiac death thought to be unrelated to the treatment. One patient had worsening of proteinuria which led to discontinuation of belatacept.

Conclusions: Belatacept conversion in proteinuric kidney transplant recipients was associated with stable allograft function and about half the patients achieved the primary outcome of 25% reduction in proteinuria. Patients without DM may experience greater reduction in proteinuria on belatacept.

Abstract# 1054

Defining the Characteristics and Graft Outcomes of Kidney Transplant Recipients with Elevated Plasma Oxalate Level Not Due to Primary Hyperoxaluria

D. Khan, N. Zhang, M. Keddis, *Mayo Clinic, Phoenix, AZ*

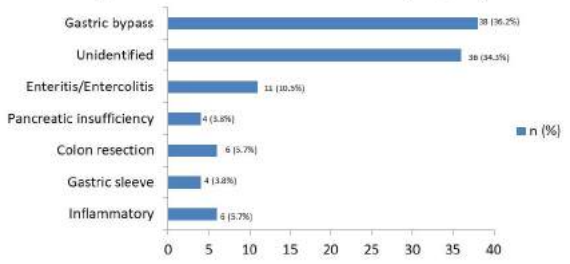
Purpose: Patients with elevated systemic oxalate burden due to enteric etiologies are at increased risk for calcium oxalate deposition causing ESRD. The objective of this study is to describe causes and graft function of kidney transplant (KTx) recipients with elevated plasma oxalate (Pox) not due to primary hyperoxaluria at our institution.

Methods: KTx recipients between 2013 to 2019 with an elevated Pox at the time of KTx evaluation were included. Chart review was performed to evaluate for enteric causes. Patients with primary hyperoxaluria (PH) were excluded

Results: 105 patients were identified. Mean age was 57.8 years, 42.9% were female, 76.2% white, and 91.4% first KTx. The most common enteric cause was Roux-en-Y gastric bypass (RYGB, 36.2%) as shown in Figure 1. 34.3% did not have an identified cause. Baseline characteristics are shown in Table 1. Patients with RYGB were significantly more likely to have diabetes (65.8%, p=0.033) but less likely to have a history of nephrolithiasis(36.8%, p=0.019) compared to patients with either unidentified (diabetes:36.1%, nephrolithiasis:52.8%) or alternative enteric cause (diabetes:45.2%, nephrolithiasis:71%) of oxalosis. Patients with RYGB had significantly higher median Pox pre-KTX than either unidentified or alternative enteric cause (15.2mcmol/L compared to 6.1mcmol/L and 11.8mcmol/L, respectively) (p= 0.032). There was no significant difference in long-term transplant outcomes noted for patients regardless of the etiology of elevated POx (with the primary transplant outcome endpoint of GFR at 1yr post-KTx). One-year GFR for patients with RGYB was 50.2±21.9mL/min/1.73m^2, compared to 53.2±18.0mL/min/1.73m^2 and 48.8±23.4mL/min/1.73m^2 for unknown and alternative enteric causes, respectively. Mean 1-year GFR for deceased donor KTx for our Transplant Center is 58.9 ±20.6ml/min/1.73m^2.

Conclusions: RYGB is the most common cause of enteric oxalosis in KTx recipients but in a third of cases, an enteric cause was never identified. There was no significant difference in GFR between the three groups; however, all groups had a lower GFR compared to the mean GFR of our transplant Center. Further studies are needed to assess the risk of enteric risk factors on long-term graft function.

Figure 1. Enteric risk factors for oxalate nephropathy



Baseline Characteristics	RYGB (n=38)	Other Enteric Causes (n=31)	Unknown (n=36)
Age (mean, SD)	59.7 (11.1)	57.6 (13.0)	55.9 (12.1)
Female (n, %)	23 (60.5%)	7 (22.6%)	15 (41.7%)
White race (n, %)	29 (76.3%)	23 (74.2%)	28 (77.8%)
Dialysis pre-KTx (n, %)	31 (86.8%)	25 (80.6%)	26 (88.9%)
History of clostridium difficile infection (n, %)	1 (2.6%)	11 (35.5%)	1 (2.8%)
Native kidney nephrolithiasis (n, %)	14 (36.8%)	22 (71.0%)	19 (52.8%)
Deceased donor transplant (n, %)	33 (89.2%)	29 (93.5%)	23 (63.9%)
Plasma oxalate >30mcmol/L (n,%)	3 (8.6%)	3 (14.3%)	1 (4.0%)

Abstract# 1055

Transplant Center Volume in High-risk Recipient Association with Graft and Patient Survival

M. A. Merzkani, H. Murad, M. Mattu, S. Husami, M. Wang, V. Hu, S. Chang, T. Alhamad, *Transplant, Washington University, Saint Louis, MO*

Purpose: Evaluation of high-risk recipients in transplant centers involves an intensive multidisciplinary medical evaluation and requires extensive coordination amongst various teams to follow-up on these patients. Understandably, this requires well thought out protocols and structures for patient safety. In this study, we explored the association of center volume with patient and graft survival in high-risk recipients.

Methods: We reviewed OPTN data on kidney transplants on high risk recipients among 285 transplant centers between 2000 and 2016. High-risk recipients were defined as age ≥70 years old or BMI≥35 kg/m2. For each of these, transplant centers were categorized into tertiles of low, medium and high volume according to average annual transplant center volume for such transplant in high-risk recipients. The association of center volume with death censored graft loss (DCGL) and death with functioning graft (DWFG) were estimated using multivariable Cox regression including adjustment for recipient, donor, and transplant characteristics.

Results: In recipients age≥ 70 years old, that there was an increased risk for DWFG in centers with low volumes of these patients at 3 month (aHR=1.337;1.053-1.697), 1 year (aHR= 1.193;1.033-1.379), 5 year (aHR=1.116;1.035-1.203), 10 year (aHR=1.072;1.010-1.136) but not overall (aHR=1.050;0.993-1.111). In centers with medium volumes of ≥ 70 years old recipients, there was an increased risk for DWFG at 1 year (aHR=1.162;1.005-1.343); 5year (aHR=1.116;1.027-1.194); 10 year (aHR=1.072;1.025-1.151) and overall (aHR=1.079;1.021-1.141). There was no difference in of DCGL in low and medium center volume for adults ≥ 70 years old. In centers with low volume for BMI≥ 35 Kg/m^2 there was increase for DCGL at 3 month (aHR=1.556;1.299-1.863) , 1 year (aHR=1.271;1.106-1.1460), 5 years (aHR=1.138;1.045-1.238) and 10 years (aHR=1.109;1.033-1.191) and overall (aHR=1.115;1.042-1.193). In medium center volume for BMI≥ 35 Kg/m^2 there was an increased risk for DCGL at 3 months (aHR=1.323; 1.103-1.508), 10 year (aHR=1.074;1.001-1.152) and overall (aHR=1.074;1.005-1.148).

Conclusions: Kidney Transplantation of high risk recipients like those who are older and/ or with obesity requires a more thorough evaluation and structured follow up. In this study, we found there is room to improve in centers with lower and medium volume for older age recipients as well as those with BMI≥ 35 Kg/m^2 to improve patient survival. Programs may need to establish more safety- net protocols targeted on such patients.

Abstract# 1056

Outcomes of Kidney Transplantation in Patients with Congenital Anomalies of the Kidney and Urinary Tract

O. A. Oto[1], Y. Caliskan[2], H. Yazici[1], S. Mirioglu[3], A. Dirim[1], N. Garayeva[1], S. Safak[1], E. Demir[1], Y. Ozluk[4], A. Artan[1], A. Turkmen[1], K. Lentine[2], *[1]Nephrology, Istanbul University, Istanbul, Turkey, [2]Nephrology, Saint Louis University School of Medicine, Saint Louis, WA, [3]Nephrology, Bezmialem Vakif University School of Medicine, Istanbul, Turkey, [4]Pathology, Istanbul University, Istanbul, Turkey*

Purpose: We aimed to compare the long-term outcomes after kidney transplantation (KTx) in patients with congenital anomalies of the kidney and urinary tract (CAKUT) versus non-CAKUT causes of kidney failure.

Methods: For this observational study, 495 prevalent KTx recipients (59% male) were classified into two groups: Patients with CAKUT (n= 175) and non-CAKUT (n= 320). Baseline demographic, clinical and laboratory characteristics, as well as follow-up outcomes, were analyzed. The primary outcome was allograft loss defined as the return to dialysis or transplantation.

Results: Patients were followed for a median of 136 (86-176) months after KTx. The study groups were similar regarding recipient gender, donor age, donor type, donor gender, HLA matching, levels of pretransplant panel reactive antibody and type of maintenance immunosuppressive treatment regimens. Recipient median age was significantly lower [25.5 (20.0-30.0) vs 31.0 (25.0-39.0), p<0.001] in the CAKUT group compared to the non-CAKUT group. Groups were comparable in post-KTx events including rejection rates, types of rejection. The incidence of urinary tract infection was significantly higher in the CAKUT group than in the non-CAKUT group (20.6% vs 10.0%, p=0.003). Median eGFR on last follow up was significantly higher in the CAKUT group [62.0 (33.6-90.6) mL/min/1.73m^2] compared to non-CAKUT [46.0 (12.6-73.5) mL/min/1.73m^2] group (p<0.001). The rate of graft loss was significantly lower in the CAKUT group (16.0%) compared to non-CAKUT controls (32.0%) (p<0.001). Kaplan Meier survival analysis revealed a better 10-year unadjusted survival rate for the CAKUT group than the non-CAKUT group (p=0.015) (Fig. 1). In univariate Cox-regression analysis, it was found that the presence of CAKUT significantly reduced the risk of graft loss (HR: 0.651, CI 95% 0.460-0.92, p=0.015). Even though this predictive effect suggested a mild trend in multivariate analysis performed with potential confounding factors such as age and pretransplant dialysis duration, it did not reach statistical significance (HR: 0.714, CI 95% 0.479-1.065, p=0.099).

Conclusions: This study suggest the favorable post-KTx course of patients with CAKUT compared to patients with kidney diseases of other etiologies.

Abstract# 1057

Hypercholesterolemia and Donor Age Impaired Capillary Vegf and Nitric Oxide (no) Expression and in Turn Decrease Both Microvascular Density and Tubule Villin Expression in Renal Allografts, Resulting in Poor Graft Survival

B. Ozdemir[1], E. Akcay[1], A. Ok Atilgan[1], M. Haberal[2], *[1]Department of Pathology, Baskent University, Ankara, Turkey, [2]Division of Transplantation, Department of General Surgery, Baskent University, Ankara, Turkey*

Purpose: The role of aging and hypercholesterolemia (HC) on endothelial cells (ECs) are not well defined. Aged ECs might produce less NO and VEGF, resulting in reduced glomerular capillaries (GCs) and peritubular capillaries (PTCs). Chronic ischemia as a result of decreasing capillaries is considered a significant factor for renal injury. To understand whether the capillary loss was due to changes in angiogenic factors affected by age and cholesterol, we investigated the impact of age and cholesterol on the density of GCs and PTCs.

Methods: Among 150 patients, 63 (42%) had HC. Antibodies CD31 and HLA-DR stained to determine the mean number of GCs and PTCs. PCNA, VEGF, and NO expression of GCs and PTCs examined. EC proliferation index (PI) of GCs and PTCs assessed by PCNA. Villin expression and PI of tubules examined. Follow-up biopsies analyzed for the development of interstitial fibrosis (IF) and glomerulosclerosis (GS).

Results: The mean capillary numbers were 38,4±15,2 and 27,6±14,4 for GCs and PTCs, respectively. VEGF and NO expression of both GCs and PTCs and the PI of all capillaries decreased with increasing donor age and cholesterol (p<0.001). The PI index of ECs showed a negative correlation with the VEGF and NO expression of both GCs and PTCs (p<0.001). The number of PTCs correlated with PTCitis (r= -0,73, P<.001), PTC-VEGF expression (r= 0,73, P<0,001), PTC-NO expression (r= 0,86, P<0.001), tubular villin expression (r= -0,83, P<.001), proteinuria (r= -0,49, P<.001), hypertension (r= -0,48, P<.001), development of IF (r= -0,74, P<0.001), graft loss (r=-0,57, P<.001). The GC loss was also significantly associated with GC inflammation (r= -0,68, P<.001), GC-VEGF expression (r=0,76, P<.001), GC-NO expression (r=0,86, P<.001), tubular villin expression (r= -0,76, P<.001), proteinuria (r= -0,64, P<.001), hypertension (r= -0,43, P<.001), development of GS (r= -0,53, P<.001), graft loss (r= -0,46, P<.001).

Conclusions: A marked loss of capillary VEGF and NO expression associated with aging and HC resulted in a significant loss of GCs and PTCs. The loss of PTCs and GCs significantly correlated with the severity of the tubular injury, proteinuria, hypertension, development of IF and GS. We suggested that donor age and HC influenced graft survival negatively by impairing the microvasculature and tubular integrity in renal allografts.

Abstract# 1058

Impact of Donated Kidney Volume and Recipient Body Surface Area Incompatibility on the Allograft Outcomes with Pre-transplant Diabetes Mellitus

Y. Park[1], H. Lee[2], E. Ko[2], C. Yang[2], B. Chung[2], *[1]Internal Medicine, Konyang University Hospital, Daejeon, Korea, Republic of, [2]Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea, Republic of*

Purpose: The aim of this study was to analyze the impact on the adverse allograft outcome of transplanting relative small kidneys in patients with pre-transplant diabetes mellitus (DM).

Methods: From January 2010 to December 2018, 1,290 KTs were performed in Seoul St Mary's Hospital. Of these, 788 cases of non-sensitized living donor kidney transplant recipient and donor pairs were enrolled. They were divided into 4 groups (non-DM large kidney, non-DM small kidney, DM large kidney, DM small kidney) according to the size incompatibility (donated kidney volume and recipient's body surface area ratio) and pre-transplant DM status. The primary outcome of this study was to analyze the effect of size incompatibility and pre-transplant DM status on the incidence of DCGL.

Results: There was no significant difference in the biopsy proven acute rejection rate among the 4 groups. DM small kidney group showed significantly higher DCGL rate (17/129 (13.2%), P = 0.008) than the other groups. The combined presence of pre-transplant DM and relative small kidney was an independent risk factor for DCGL (adjusted hazard ratio 2.921, P = 0.019), and these showed significant interaction with each other (P for interaction < 0.001). Moreover, renal function after 4 years of transplantation worsened faster in the DM small kidney group compared to the other groups, and allograft survival decreased after 1 year of transplantation.

Conclusions: Our results suggest that transplanting large kidneys rather than small kidneys is considered to have an advantage in terms of allograft outcome in pre-transplant DM patients, and this should be considered in donor selection.

Cox proportional hazard ratio model analysis for death censored graft loss					
	Univariable HR (95% CI)	P-value	Multivariable HR (95% CI)	P-value	P-value for interaction

Abstract# 1059

Cancer Among Kidney Transplant Recipients More Than 20 Years After Transplantation: PTLD Remains the Most Common Cancer Type Even in the Very Long-Term

T. Schachtner, J. Fuhrmann, T. Mueller, *Nephrology, University Hospital Zurich, Zurich, Switzerland*

Purpose: Due to an improved patient and kidney allograft survival, cancer is increasingly recognized as the major cause of death after kidney transplantation. Cancer risk is increased by two- to four-fold in kidney transplant recipients (KTRs) and tends to be higher than in age-matched individuals from the general population. KTRs with long-term survival of more than 20 years, however, haven't been studied so far.

Methods: We followed 294 KTRs with kidney allograft survival of more than 20 years on a quarterly/yearly basis in our kidney transplant outpatient clinic. KTRs were analyzed for the development of cancer, cancer type, cancer-associated risk factors, and patient and kidney allograft outcomes.

Results: By 10, 20, and 30 years post-transplant KTRs showed an incidence of cancer of 10.4%, 14.6% and 39.9%, and an incidence of non-melanoma skin cancer (NMSC) of 10.3%, 33.5%, and 76.8%. By recipient age of 40, 60, and 80 years KTRs showed an incidence of cancer of 3.4%, 14.5%, and 55.2%, and an incidence of NMSC of 1.7%, 31.6%, and 85.2%. By 30 years post-transplant PTLD showed the highest incidence of 7.3% followed by renal cell carcinoma with 4.3%. Risk factors associated with the development of cancer included recipient age, the time on maintenance immunosuppression, and smoking. Risk factors associated with the development of NMSC included recipient age, the time on maintenance immunosuppression, and the use of thiazide diuretics. KTRs with cancer showed inferior patient survival with 25-year patient survival of 75.2% vs. 85.6%, and 30-year patient survival of 56.1% vs. 66.7%. No differences were observed concerning death-censored kidney allograft survival or the development of donor-specific antibodies (p>0.05).

Conclusions: With increasing patient and kidney allograft survival, cancer is becoming the major cause of mortality and morbidity, and PTLD remains the most common cancer type even in the very long-term. Emphasis should be placed on adherence to cancer surveillance protocols for early detection and prompt management.

Abstract# 1060

Changes in Glomerular Filtration Rate (delta Egfr) within the First Year Predict Long-Term Outcomes of Renal Grafts

A. M. Thompson, M. Zenati, S. Hariharan, M. Molinari, *Starzl Transplant Institute, UPMC, Pittsburgh, PA*

Purpose: The relationship between changes in eGFR (Delta eGFR) during the first year after renal transplantation (RT) and long-term graft survival are poorly understood. We hypothesized that Delta eGFR is an independent predictor of long-term graft outcomes.

Methods: A retrospective analysis of all live or deceased donor RT at a single center between 2013-2019 was performed irrespective of primary diagnosis of renal failure and history of previous RT. Pediatric and recipients of multivisceral transplants were excluded. Delta eGFR (ml/min) was defined as the difference between eGFR at 12 months and eGFR at 3 months after surgery. The cohort was stratified into four groups: group I (Delta eGFR <0), group II (Delta eGFR=1-15), group III (Delta eGFR 16-30), and group IV (>30 mL/min). We performed correlation and regression analyses to assess if Delta eGFR was an independent predictor of graft failure.
Results: A total of 998 patients were included. Median age was 58 years, 41% were females, 81% underwent first time RT. Hypertensive and diabetic nephropathy represented the most common indications for RT (15% and 18% respectively). 564 (56%) patients were in group I, 309 (31%), 91 (9.1%) and 34 (3.4%) in group II, III and IV respectively. At 60 months, the mean eGFR was 51 ml/min (+24), 45 (+22), 41 (+23) and 26 (+23) for Group I-IV respectively(P<0.001). 5-year graft survival was 82%, 77% 66% and 50% for Group I-IV respectively (p<0.001) (Figure 1). Cox regression analysis showed that after adjusting for recipient age, sex, ethnicity, PRA, time on dialysis and KDPI, Delta eGFR was an independent predictor for graft survival. Using Group I as reference, the adjusted HR were 1.3 (95% CI 0.89-2.06; P=0.15), 1.9 (95% CI 1.06-3.61; P=0.03), 5.6 (95%CI 2.62-12.25; P<0.001) respectively (Figure 2).
Conclusions: The degree of decline in eGFR observed during the first year after renal transplantation is an independent predictor of long-term graft function.

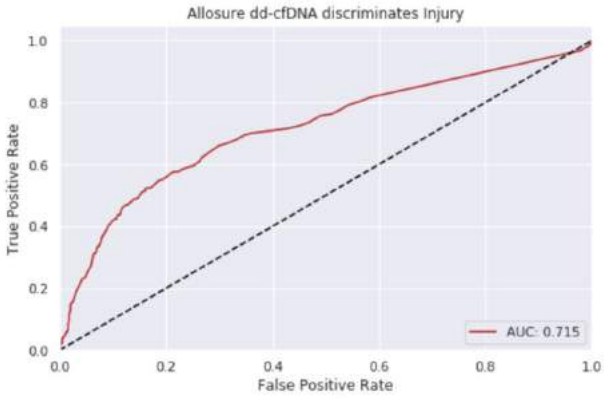
Kidney Complications: Immune Mediated Late Graft Failure

Abstract# 1061

Donor-Derived Cell-Free DNA as a Surrogate Marker for "Allograft Quiescence" After Kidney Transplantation

J. S. Bromberg[1], L. Bu[2], G. Gupta[3], I. Moinuddin[3], S. Anand[4], A. Pai[5], T. Alhamad[6], V. Bowers[7], S. Ghosh[8], W. Tian[8], E. Stites[9], *[1]University of Maryland School of Medicine, Baltimore, MD, [2]University of Minnesota, Minneapolis, MN, [3]Virginia Commonwealth University, Richmond, VA, [4]Intermountain Medical Center, Murray, UT, [5]University of Texas McGovern Medical School, Houston, TX, [6]Washington University in St. Louis, St. Louis, MO, [7]Tampa General Hospital, Tampa, FL, [8]CareDx, Brisbane, CA, [9]University of Colorado, Aurora, CO*
Purpose: Donor-derived cell-free DNA (dd-cfDNA; AlloSure®) and the association with active rejection (AR) was described by Bloom *et al*, however subsequent insights have suggested this analyte as a molecular marker of *injury* rather than specific for AR. Since prior validation demonstrated dd-cfDNA with high negative predictive value (NPV) for AR, our aim was to assess value of this biomarker for predicting *"quiescence"* across aggregated pathological diagnoses putatively associated with allograft injury.
Methods: 1092 patients from the Assessing dd-cfDNA monitoring insights of renal allograft with longitudinal surveillance (ADMIRAL study; clinicaltrials.gov: NCT04566055219) were analyzed. All patients had dd-cfDNA (AlloSure®; CareDx) with standard post-transplant surveillance and all clinical events captured. "Injury" was defined as the aggregated diagnoses: acute tubular injury, BK nephropathy, de novo DSA, histological AR or "other pathology" as confirmed by paired biopsy ≤20 days after dd-cfDNA measurement.
Results: 341 unique patients were pooled in the "injury cohort", with a median dd-cfDNA = 0.52% (IQR:1.3%-0.25%); 693 patients with the absence of specified pathology or no prescribed biopsy were defined as the cohort with "allograft quiescence" with a median dd-cfDNA = 0.24% (IQR:0.39%-0.19%). The AUC for the allograft quiescence analysis was 0.715 [**FIGURE 1**]. A dd-cfDNA threshold of 0.5% was associated with sensitivity and specificity for quiescence of 70% and 63%, respectively.

FIGURE 1.



Conclusions: The high NPV for a low dd-cfDNA plasma level supports previous literature in clarifying an absence of significant concurrent pathology, thereby providing value in risk-stratifying the stable patient. This offers a potential *"peace of mind"* metric to both patient and clinician when developing precision medicine. Conversely, elevation of dd-cfDNA above the threshold of 0.5%, suggests development of significant allograft injury.

Abstract# 1062

Association of Donor-Derived Cell-Free DNA with Severity of Interstitial Fibrosis and Cortical Atrophy Lesions Following Kidney Transplantation

L. Bu[1], E. Stites[2], V. Bowers[3], T. Alhamad[4], J. S. Bromberg[5], G. Gupta[6], I. Moinuddin[6], S. Ghosh[7], W. Tian[7], A. Pai[8], S. Anand[9], *[1]University of Minnesota, Minneapolis, MN, [2]University of Colorado, Aurora, CO, [3]Tampa General Hospital, Tampa, FL, [4]Washington University in St. Louis, St. Louis, MO, [5]University of Maryland School of Medicine, Baltimore, MD, [6]Virginia Commonwealth University, Richmond, VA, [7]CareDx, Brisbane, CA, [8]University of Texas McGovern Medical School, Houston, TX, [9]Intermountain Medical Center, Murray, UT*

Purpose: The most common cause of kidney transplant (KT) failure is the poorly characterized histopathologic entity *"interstitial fibrosis and tubular atrophy"* (IFTA). There are no known unifying mechanisms, nor effective therapy, with diagnosis dependent on biopsy. Incidence of IFTA is ~50% at 1-yr post-KT, 70% at 2-yr, and nearly universal after 10-yr. The combination of IFTA with inflammation is associated with worsened prognosis than fibrosis alone. Considering the multifactorial pathogenesis of IFTA, the aggregation of mechanisms of injury using dd-cfDNA may allow surrogate quantification of inflammation.

Methods: 299 patients with paired donor-derived cell-free DNA (dd-cfDNA, AlloSure®; CareDx.) and biopsy (Bx) visits were examined from the Assessing dd-cfDNA monitoring insights of renal allograft with longitudinal surveillance (ADMIRAL study; clinicaltrials.gov: NCT04566055219). Bx performed ≤ 20 days after the dd-cfDNA level, combination of "protocol" and clinical" for cause". Pathology reports were centrally read and scored, and correlated with histology lesion and dd-cfDNA results. High dd-cfDNA was defined as >0.5% based on previous injury analysis based on ADMIRAL cohort. Interstitial fibrosis (ci) scores were grouped based on the Banff 2018 update. Ci(0)—Interstitial fibrosis in ≤5% of cortical area (normal), ci(1)—Interstitial fibrosis in 6-25% (mild), ci(2)—Interstitial fibrosis in 26-50% (moderate), ci(3)—Interstitial fibrosis in >50% of cortical area (severe).

Results: dd-cfDNA was significantly elevated when Bx normal patients were compared to those mild to severe (ci). Mild: p= 0.006, moderate: p= 0.01, severe: p= 0.001

	Normal	Mild	Moderate	Severe
Number of Biopsies (N)	118	100	43	5
Median AlloSure (%)	0.3	0.42	0.79	1.17

Conclusions: The Banff Classification does not provide precise definition for individual areas of interstitial fibrosis. These results demonstrate a positive correlation between severity of IFTA and allograft injury assessed using dd-cfDNA. Consideration of dd-cfDNA levels with interpretation of histology, may be a useful adjunct in the assessment of *interstitial fibrosis,* as well as metrics to measure effectiveness of potential therapies.

Abstract# 1063

Recurrence and Outcome of Anti-GBM Glomerulonephritis After Kidney Transplantation: A Belgian Multicenter Study

S. Coche, *Nephrology, Cliniques Universitaires Saint-Luc, Brussels, Belgium*

Purpose: Recurrence of anti-glomerular basement membrane (anti-GBM) glomerulonephritis (GN) in the kidney graft is a rare event, described in limited case reports and registry analysis. The aim of this study was to evaluate in a large cohort of patients with detailed data collection and long follow-up the risk of recurrence of anti-GBM disease and graft loss caused by recurrence, the risk factors associated with clinical recurrence and the long-term patient and graft survival.

Methods: Multicenter retrospective study. Inclusion criteria: patients with anti-GBM GN transplanted with a kidney between 1977 and 2015. Exclusion criteria: systemic vasculitis (except ANCA), lupus erythematosus and cryoglobulinemia. Clinical recurrence was defined as reappearance of signs of GN along with histological signs of proliferative GN and linear IgG staining on kidney biopsy, with or without anti-GBM antibodies.

Results: Fifty-three patients were included. Clinical recurrence in a first kidney transplant occurred in only one patient five years after transplantation -a prevalence rate of 1.9%- in the context of cessation of immunosuppressive drugs. The graft was lost due to recurrence. Histological recurrence with linear IgG staining on kidney biopsy in the absence of histologic signs of proliferative GN was observed in four patients, in the context of cellular rejection. Two patients lost their kidney graft from severe acute rejection; the others fully recovered. Patient survival was 100%, 94% and 89% at 5, 10 and 15 years, respectively. Overall, death-censored first graft survival rates were 88%, 83% and 79% at 5, 10 and 15 years, respectively.

Conclusions: Recurrence rate of anti-GBM glomerulonephritis after transplantation is very low, and associated with graft loss. The long-term patient and graft survival rates are excellent.

Table 2. Demographic characteristics of patients with anti-GBM mediated glomerulonephritis at first kidney transplantation (KT)

Age, y, median (P25-P75)	43 (27-59)

Abstract# 1064

PLA2R Status and Antibody Mediated Rejection in Kidney Transplant with Membranous Nephropathy

H. S. Han[1], A. Urisman[2], J. Shoji[1], *[1]Kidney Transplant Service, University of California, San Francisco, San Francisco, CA, [2]Pathology, University of California, San Francisco, San Francisco, CA*

Purpose: Membranous nephropathy (MN) in transplanted kidney is categorized as de novo or recurrent disease. This immune complex glomerulopathy presents with varying levels of proteinuria, and antibodies against phospholipase A2 receptor (PLA2R) have been detected. The long-term outcomes of renal allografts with MN have not been well-defined. Previous studies suggest that post-transplant MN may be associated with alloimmune response. We examined the natural progression of all renal transplants at our center with biopsy-proven MN to identify risk factors for developing this disease and to explore a possible link with acute antibody mediated rejection (AMR).
Methods: We retrospectively analyzed renal transplant biopsies with MN done at our center from 2014 to 2020. Patients with systemic lupus erythematosus (SLE) were excluded from this study. Data including age, sex, race, type of transplant, etiology of ESRD, cPRA, induction agent, maintenance regimen, serum creatinine, eGFR, urine protein-to-creatinine ratio, DSA, and biopsy results were collected. If a patient had more than 1 biopsy, the patient was added to the PLA2R positive or AMR group if at least 1 biopsy suggested PLA2R positivity or acute AMR.
Results: 52 biopsies with post-transplant MN from 31 patients were included in this study. AMR was observed in 33% of the patients with de novo disease (n=15), 45% in recurrent disease (n=11), and 50% in patients with unknown cause of initial ESRD (n=4) (Table 1). PLA2R stains were positive in 40% of patients with de novo disease, 82% of recurrent group, and 60% of patients with unknown cause of ESRD. 44% of the patients with PLA2R positivity had concomitant acute AMR (n=18), while 31% of the PLA2R negative patients had AMR (n=13).
Conclusions: PLA2R positivity was statistically higher in recurrent disease than in de novo disease (p=0.018) suggesting more frequent secondary MN in the de novo group. Although not statistically significant, a trend for more frequent AMR was observed in the recurrent group (p=0.084). However, PLA2R status did not show a correlation with AMR. In addition, our results do not provide support for the hypothesized link between de novo MN and AMR.

Membranous Nephropathy, AMR, and PLA2R staining results					
	PLA2R+ and AMR	PLA2R- and AMR	PLA2R+ and No AMR	PLA2R- and No AMR	Total
De Novo	3	2	3	7	15
Recurrent	4	1	5	1	11
Unknown	1	1	2	1	5
Total	8	4	10	9

Abstract# 1065

Characterization of Chronic Renal Allograft Dysfunction at Single Cell Resolution

C. Kuscu[1], C. Kuscu[2], A. Shetty[3], M. Talwar[4], J. Eason[2], D. G. Maluf[5], V. Mas[6], *[1]Surgery, James D Eason Transplant Institute, UTHSC, Memphis, TN, [2]Surgery, James D Eason Transplant Institute, Memphis, TN, [3]Institute for Genome Sciences, School of Medicine, University of Maryland, Baltimore, MD, [4]Nephrology, James D Eason Transplant Institute, Memphis, TN, [5]Surgery, Program in Transplantation - University of Maryland, Baltimore, MD, [6]Surgery, Division of Surgical Science - University of Maryland, Baltimore, MD*

Purpose: Chronic allograft dysfunction (CAD) is one of the major complications after kidney transplantation. Hereby, we aim to assess the molecular and cellular mechanism of Chronic Allograft Dysfunction at a single cell resolution to identify potential interventions. Single-cell genomics has played unprecedented role for diagnosis and finding novel treatment methods.
Methods: We performed single nuclei sequencing from 8 kidney allograft biopsies (3 normal allografts (normal histology and normal creatinine at 24 months post-transplant), 2 Chronic Allograft Dysfunction (CAD) with inflammation, and 3 CAD without inflammation) using droplet based 10X Genomics Chromium platform. Data is analyzed on "Cell-Ranger" pipeline and "Seurat" package was used for cell clustering and cell identification. CAD classifications were done using Banff criteria.
Results: We obtained >40,000 cells in our analysis with an average of 1400 genes per cell (Fig 1a). We identified 17 different clusters in aggregated analysis. Our single-nuclei RNA-seq allow us to identify rare pericytes and kidney progenitor cells in addition to the main cell types of kidney such as tubular cells and endothelial cells (Fig 1 A-B). Interestingly, we identified significant number podocytes which cannot be detected by ordinary single-cell RNA sequencing. ARL17B and FKBP5 genes are found to be differentially expressed in several cell types including tubular cells, podocytes when CAD(- inflammation) compared to CAD(+ inflammation).
Conclusions: Our results identified pericytes and kidney progenitor cells (in addition to the main cell types of kidney such as tubular cells and endothelial cells) in patients with chronic allograft dysfunction

Abstract# 1066

Risk Factors for Mortality in Kidney Transplant Patients Infected by Sars-cov-2 in South of Spain

V. Lopez[1], T. Vazquez[1], C. Casas[1], I. Poveda[2], J. Alonso[1], D. Hernandez[1], *[1]Nephrology, Nephrology Department, Hospital Regional Universitario de Málaga and University of Málaga, IBIMA, REDinREN (RD16/0009/0006), Málaga, Spain, Málaga, Spain, [2]Nephrology, Nephrology Department, Hospital Torrecárdenas, Almería., Málaga, Spain*

Purpose: Covid-19 pandemic has especially affected kidney transplant (KT) recipients, who are more vulnerable than the general population due to their immunosuppressive status and added comorbidities. The objetic of this study was to determine risk factors related to infection and mortality from Covid-19 in KT.

Methods: We included 53 KT who had PCR-confirmed COVID-19 infection between march 21st and november 24th, from a total of 2030 KT. Outcomes related to patient survival were analyzed.

Results: 39 (73%) patients were men, with a mean age of 56±15 years old. Median time after KT where the infection took place was 104 months (IQR: 55-160). One patient was infected 40 days after transplant. 90% were on Tacrolimus therapy and 79% on MMF. 81% of patients were hypertensive, 36% diabetic and 19% had ischemic heart disease. 65% were on ARAII treatment. Clinical presentation consisted on pneumonia (64%), fever (55%), cough (70%), dyspnoea (45%), lymphopenia (66%) and gastrointestinal symptoms (36%). 21% required intubation and admission in ICU. 8 patients were asymptomatic. 18% received Hydroxychloroquine therapy plus Azithromycin, 11% Tocilizumab, 11% Ritonavir-Lopinavir, 59% steroids, 7.7% Remdesivir and 13.5% convalescent plasma. Immunosuppression was reduced in all symptomatic patients. 10 patients (19%) died. Table 1 compares the characteristics of these patients with those who survived.

Conclusions: We concluded that mortality in KT is very high, more than reported in general population. Risk factors are patient age, time after KT, baseline renal function, the presence of pneumonia, as well as higher CRP levels at the time of diagnosis. More experience is needed to optimize our protocols and therapy for Covid-19 in KT.

Table 1: Comparison between the characteristics of patients who live and die.

Abstract# 1067

Intermediate Outcomes Following Early Inflammatory Changes on Surveillance Biopsies

I. Melgarejo[1], V. Viswanathan[2], A. Sharma[1], P. Sood[1], C. Puttarajappa[1], N. Shah[1], M. Molinari[1], A. Tevar[1], C. Wu[1], S. Hariharan[1], R. Mehta[1], *[1]Starzl Transplant Institute, University of Pittsburgh Medical Center, Pittsburgh, PA, [2]Department of Renal-electrolyte, University of Pittsburgh Medical Center, Pittsburgh, PA*

Purpose: The implications on early inflammatory changes on surveillance biopsies on intermediate and long-term outcomes is unclear.

Methods: Of the 1000 kidney transplant (live donor and deceased donor) recipients at our center between Jan 2013 through Dec 2017, we prospectively followed a cohort of 518 recipients who had 3 month surveillance biopsies. These were divided into Group 1 - no major abnormality (NMA; i0t0 and i>0;t0; n=278); Group 2 - Borderline Changes (BL-R; i≥1;t≥1 but not meeting criteria for Banff IA; n=161) and Group 3 - Subclinical T cell mediated rejection (SCR; i2t2 and higher; n=79). We excluded patients who could not undergo 3 m surveillance biopsies and those who had clinical rejections prior to index biopsy. BL-R was treated in a minority of cases with one dose of 250 mg of methylprednisolone, while SCR was treated with methylprednisolone 250 mg iv x 3. Baseline demographics between the groups including recipient age, race, sex, prior transplant and sensitization was similar between the groups. Majority of the patients received thymoglobulin induction (>95%) and maintenance IS with tac and MMF. Median period of follow up was 4.5 years (IQR 3.5-7.8). We studied the composite endpoint of subsequent clinical rejections and death censored graft loss (DCGL) in all groups and also the hard endpoint of DCGL alone.

Results: Figure 1. Figure 2.

Conclusions: 1. The hazard ratio for reaching the composite endpoint of clinical rejection or DCGL increased in the BL-R and SCR groups compared to NMA (HR 2.3; p=0.001; 95% CI 1.4-3.7). 2. The hard endpoint of DCGL was not different among the groups in the intermediate term. 3. Long term follow up will be helpful to detect any long term implications of early inflammatory changes on surveillance biopsies

Abstract# 1068

A Case of Graft-versus-Host Disease Following Pancreas-Kidney Transplant

P. Shelat[1], C. Alquist[2], *[1]Pathology, University of Cincinnati Medical Center, Cincinnati, OH, [2]Transplantation Immunology Division, Hoxworth Blood Center, Cincinnati, OH*

Purpose: Graft-versus-host disease (GvHD) is an uncommon but often fatal complication following solid organ transplantation. It occurs when immunocompetent donor T cells are transferred to the recipient from within the graft. Most commonly encountered after small bowel and liver transplants, secondary to lymphoid tissue content, few cases have been identified following kidney-pancreas transplant.

Methods: A retrospective case review was performed to evaluate clinical presentation, treatment and response timelines, chimerism analysis, and histologic findings of gastrointestinal and bone marrow biopsies in a rare case of GvHD following simultaneous kidney-pancreas (SKP) transplant.
Results: A 38-year-old woman with past medical history of end-stage renal disease secondary to type 1 diabetes mellitus received an complicated SKP transplant. Fevers, chills, abdominal pain, and diarrhea developed one-month post-transplant. An infectious cause work up was negative. Chimeric studies displayed 23% donor T-cells. A gastrointestinal biopsy was highly suspicious for GvHD. She was treated with intravenous steroids, ruxolitinib, and extracorporeal photopheresis. Despite these interventions, chimeric studies showed a rising proportion of donor T-cells. At 6 weeks post-transplant, T cells were reported as 100% donor composition and the patient exhibited a diffuse rash. A bone marrow biopsy revealed markedly hypocellular marrow. The patient was transferred to an outside hospital for consideration of a bone marrow transplant for definitive treatment of GvHD. The patient then developed a persistent bacteremia with multi-drug resistance and Epstein Barr viremia. Rituximab was initiated for post-transplant lymphoproliferative disorder. She was transferred back to our institution after being deemed ineligible for a bone marrow transplant secondary to multiple opportunistic infections. Hospice care was initiated and the patient expired shortly thereafter.
Conclusions: This case details the clinical and pathologic findings associated with a rare case of fatal graft-versus-host disease following SKP transplant. While this diagnosis is rare in the field of solid organ transplant, particularly in SKP scenarios, early recognition and intervention may permit successful treatments in future cases.

Abstract# LB 77

The Importance of Persistent and Recurrent T Cell Mediated Rejection in Tacrolimus Treated Renal Transplant Recipients

C. Rampersad[1], I. W. Gibson[2], D. N. Rush[1], D. Pochinco[3], P. E. Birk[4], A. Goldberg[4], T. Blydt-Hansen[5], M. Karpinski[1], J. Shaw[1], J. Ho[1], P. W. Nickerson[1], C. Wiebe[1], *[1]Department of Medicine, University of Manitoba, Winnipeg, MB, Canada, [2]Department of Pathology, University of Manitoba, Winnipeg, MB, Canada, [3]Shared Health Services Manitoba, Winnipeg, MB, Canada, [4]Department of Pediatrics and Child Health, University of Manitoba, Winnipeg, MB, Canada, [5]Department of Pediatrics, University of British Columbia, Winnipeg, MB, Canada*

Purpose: Optimal follow-up after treatment for T-cell mediated rejection (TCMR) is not well-established. We sought to identify the prevalence and clinical associations of repeated TCMR events.
Methods: We retrospectively reviewed consecutive renal transplant recipients from 2001-2019 at a single-center which utilizes an early surveillance biopsy program.
Results: 2,083 biopsies were performed in 777 recipients and TCMR was detected in 229 recipients, with the majority (61%) being Banff borderline rejection. 179 recipients had a follow-up biopsy at a median of 3 months (IQR 1.3-8.5). Persistent TCMR was found in 50% of recipients at a median of 2.4 months (IQR 1.1-6.3 months). Recurrent TCMR after a negative follow-up biopsy was found in 14% of recipients at a median of 12 months (IQR 2.9-22.7). Subsequent follow-up biopsies revealed that after each additional TCMR event >50% of recipients had another TCMR. Repeated events correlated with HLA-DR/DQ alloimmune risk category. Recipients with persistent or recurrent TCMR had similar clinical outcomes and were analyzed together as recipients with "Multiple TCMR". Recipients were more likely to have repeated TCMR events if they were younger, had greater coefficient of variation in tacrolimus trough levels, or had intermediate or high alloimmune risk categorized by HLA-DR/DQ single molecule eplet mismatch scores (p=0.0003). Allograft survival and dnDSA-free survival were decreased in recipients with single TCMR compared to no TCMR, and in recipients with multiple TCMR compared to either group (p<0.0001). (Figure 1) The correlation between allograft survival and TCMR episode number was also significant in the subset whose first TCMR biopsy was Banff borderline TCMR.
Conclusions: Repeated TCMR events are common despite standard immunosuppression and correlate with dnDSA development and allograft loss. HLA molecular mismatch and recipient age at time of transplant may identify high-risk patients and help enrich patients to study novel therapies.

Figure 1. Graft Survival by number of TCMR episodes

Kidney Paired Exchange

Abstract# 1069

An Early Look at the OPTN Kidney Paired Donation Pilot Program's New Priority Points Policy

S. E. Booker[1], R. Leishman[1], D. E. Stewart[1], T. Sandholm[2], J. Dickerson[3], M. Pavlakis[4], V. Casingal[5], *[1]United Network for Organ Sharing, Richmond, VA, [2]Carnegie Mellon University, Pittsburgh, PA, [3]University of Maryland, College Park, MD, [4]Beth Israel Deaconess Medical Center, Boston, MA, [5]Carolinas Medical Center, Charlotte, NC*

Purpose: The OPTN implemented new policy on 10/24/19 changing how Kidney Paired Donation Pilot Program (KPDPP) priority points are awarded. The policy is intended to improve equity in access to transplant for highly sensitized candidates and pairs with difficult-to-match blood types, and to prevent the donor-candidate pool from becoming dominated by difficult-to-match pairs. The policy adopted a sliding scale for CPRA points and added points for candidate and paired donor ABO.
Methods: OPTN data were analyzed for the characteristics of pairs who matched in KPDPP match runs in the first 4.5 months after policy revision ("post-policy": 10/24/19-3/12/20) compared with the year prior ("pre-policy": 10/24/18-3/12/19).
Results: Post-policy, there were fewer matches (N=181 pre-policy vs N=141 post-policy) but a higher overall match rate (3.97% vs 4.68%) (Table). There were 8 matches for highly sensitized candidates (CPRA 98-100%) pre-policy and 6 post-policy (4.9% vs 4.7% of matches); match rates for these candidates were unchanged post-policy (0.52% vs 0.56%). The match rate increased non-significantly for candidates with CPRA 80-97% (4.05% vs 6.19%; p=0.17). Matches by candidate blood type were virtually unchanged post-policy (A: 39.6% vs 37.2%; O: 39.6% vs 40.3%; B: 19.5% vs 20.2%; AB: 1.2% vs 2.3%); match rates increased non-significantly for AB candidates post-policy (3.39% vs 18.75%, p=0.06) but were similar for other candidate blood types (A: 8.11% vs 8.11%; O: 2.08% vs 2.66%; B: 5.58% vs 5.76%). Matches for pairs with type AB and type O paired donors increased post-policy while matches for pairs with type A and type B donors decreased (AB: 1.8% vs 6.2%; O: 38.4% vs 45%; A: 40.9% vs 32.6%; B: 18.9% vs 16.3%). Match rates increased for

candidates with type A, O and AB paired donors (A: 2.89% vs 3.18%; O: 6.18% vs 8.3%; AB: 1.05% vs 3.65%) and decreased for candidates with type B paired donors (3.33% vs 2.7%); no changes were statistically significant (p>0.05 for all).
Conclusions: The KPDPP priority points revisions are intended to improve matching opportunities for highly sensitized candidates and pairs with difficult-to-match blood types, and to add liquidity to the pair pool over time by not depleting easier-to-match pairs. Although initial results are not statistically significant, a net positive impact may be observable with more time; this will be further assessed.

OPTN Kidney Paired Donation Pilot Program Matches and Match Rates by Pair Characteristics and Policy Era

Abstract# 1070

Impact of Pre-Screening on OPTN Kidney Paired Donation Pilot Program Transplant and Refusal Rates

S. E. Booker[1], R. Leishman[1], J. Musick[1], M. Oley[1], T. Sandholm[2], J. Dickerson[3], M. Pavlakis[4], V. Casingal[5], *[1]UNOS, Richmond, VA, [2]Carnegie Mellon University, Pittsburgh, PA, [3]University of Maryland, College Park, MD, [4]Beth Israel Deaconess Medical Center, Boston, MA, [5]Carolinas Medical Center, Charlotte, NC*

Purpose: The OPTN Kidney Paired Donation Pilot Program (KPDPP) donor pre-screen tool allows centers to review and pre-accept or pre-refuse potential donors for individual candidates before match runs. Pre-screening is optional unless the candidate's CPRA is >=90%. The intent of pre-screening is to improve match quality and reduce match refusals, thereby increasing the number of exchanges that proceed to transplant. Our objective was to assess the impact of pre-screening on transplant and refusal rates.
Methods: We analyzed OPTN data for all KPDPP match offers from 1/1/15-12/31/19 by utilization of pre-screening. We evaluated matches by whether they were pre-accepted or unscreened; pre-refusing a donor precludes the candidate from matching with that donor during the match run.
Results: The KPDPP made 2463 match offers during the cohort including 2178 offers to KPD candidates (285 were bridge donors or exchange-ending donors). Of matches to KPD candidates, 1024 (47%) were refused, 948 (43.5%) were accepted but fell through due to a refusal elsewhere in the exchange, and 206 (9.5%) resulted in a transplant. 53.9% (N=1175) were pre-accepted; 46.1% (N=1003) were unscreened. Pre-accepted matches had a significantly higher transplant rate vs unscreened matches (11.4% vs 7.2%, p=0.0010) and a significantly lower refusal rate (42% vs 52.9%, p<0.0001). Pre-accepted matches had a significantly lower rate of refusals due to matched donor characteristics (p<0.0001) (Figure 1), notably due to fewer refusals for donor age, height/weight/BMI, and medical history (Figure 2). Crossmatch-related refusal rates were also lower for pre-accepted matches, though not statistically significant (p=0.09), driven by fewer positive virtual crossmatches and fewer matches with an unacceptable number of HLA mismatches. Pre-accepted matches also had fewer candidate-related refusals (p=0.11), driven by fewer refusals due to a candidate's involvement in a pending exchange with another KPD program.
Conclusions: Pre-screening increases the likelihood that a KPD match will proceed to transplant, though matches may still fall through due to a refusal elsewhere in the exchange. The most notable impact of pre-screening was a reduction in refusals due to matched donor characteristics, specifically age, body size and medical history. Additional voluntary or policy-required pre-screening could further reduce match refusals.

Abstract# 1071

First Promising Results of CIAT: A New Kidney Exchange Program for Difficult-to-match Patients

M. de Klerk[1], J. Kal[1], K. Glorie[2], D. Roelen[3], M. Betjes[1], J. Wetering van de[1], M. Kho[1], J. Roodnat[1], *[1]Erasmus MC, Rotterdam, Netherlands, [2]EQI, Erasmus University, Rotterdam, Netherlands, [3]LUMC, Leiden, Netherlands*

Purpose: Computerised Integration of Alternative Transplantation (CIAT) programs was developed to increase the chances of highly immunized (HI) and longwaiting (LW) kidney transplant candidates. CIAT integrates AB0-desensitisation, HLA-desensitisation, donor-exchange, altruistic and domino-paired donation. Strict criteria were defined for selected HI (sHI) patients. sHI patients are given priority, and dependent on titers, AB0-incompatible (AB0i) and/or HLA-incompatible matching (HLAi) is allowed. Long-waiting (LW) blood type 0 candidates (>2y dialysis) can opt for an AB0i match. In a 1 center simulation of 2015-2016 , CIAT matched 8 out of 20 participating sHI patients. Desensitisation was indicated for 3 patients: 1 AB0i, 1 HLAi and 1 both AB0i and HLAi. Five transplantations could be done without desensitisation.
Methods: A 1 center pilot was established from 2017 onwards to gain logistic experience, to test the algorithm and to optimize the program. Protocols have been created and pathways were developed for recognition of sHI and LW candidates, for logistics and patient information.
Results: Between 2017-2020, 115 couples, 20 unspecified donors and 18 sHI patients were included in CIAT, 56 transplantations were accomplished: 52 compatible, and 4 AB0i transplantations. 10 sHI patients were matched. 2 HLAi transplantations were cancelled during COVID. 8 were transplanted: 5 compatible and 3 AB0i

transplantations. Their median vPRA was 95% (range 85-100), median age 54 years (range 26-76) and median waiting time 5y(range 2y- 9y). 12 LW patients were transplanted: 11 compatible and 1 AB0i, median waiting time 3y (2y- 6y). 5 unspecified donors donated to the waitlist, 15 initiated chains (9 with 1 and 6 with 2 incompatible pairs). There were 6 kidney-exchange cycles with 2 and 1 with 3 incompatible pairs. CIAT runs were performed between national runs. In the same period 16 pairs were transplanted through the national exchange program, no sHI patients were matched.

Conclusions: The pilot yields very promising results for the sHI and LW candidates. Negotiations on national implementation, replacing the current kidney exchange program, are ongoing. Extrapolation of our results to national size would mean between 16-20 sHI candidates transplanted per year. Apart from an enormous health-gain for sHI and LW patients this means a vast reduction of healthcare costs.

Abstract# 1072

"I Would Do Whatever It Took": Understanding the Motivation, Education and Experiences of Kidney Paired Donation Participants

R. Pines[1], Y. A. Iraheta[2], L. Ambriz[2], K. A. Dahmani[2], E. H. Wood[2], M. Cooper[3], A. D. Waterman[2], *[1]Santa Barbara Cottage Hospital, Santa Barbara, CA, [2]UCLA David Geffen School of Medicine, Los Angeles, CA, [3]Medstar Georgetown Transplant Institute, Washington, DC*

Purpose: To improve kidney paired donation (KPD) educational programs, we conducted semi-structured interviews to understand motivations of past recipients and donors to participate in KPD, the educational content received, and recommendations to better prepare participants, particularly those facing KPD challenges.

Methods: We interviewed 43 KPD participants [25 living donors (64% white, 64% female; 18 recipients (44% white, 39% female)]. Data from open-ended questions were analyzed using thematic analysis. Descriptive statistics were run for quantitative items.

Results: While deciding to participate in KPD was a systematic (i.e., logical, carefully considered) process for some, for most, it was a heuristic (i.e., quickly made, often emotion-based) process. Individuals became motivated to donate because of KPD's ability to help multiple people obtain transplants and receive a transplant quickly. KPD educational content received varied, with recipients reporting receiving less information than donors on many topics (Table). Although most described the helpfulness of transplant coordinators, more review of KPD educational information provided from credible sources and the opportunity to speak to a former KPD participant were recommended. Those who faced KPD challenges requested more information about the financial protections and assistance that certain KPD programs may offer, and more psychological education and support during and after KPD.

Conclusions: Educational content provided to donors and recipients about the risks and benefits of KPD varies. Standardized, health literate educational content about KPD that enables individuals considering KPD to learn from previous KPD participants may help increase informed decision making.

Table. Educational Topics

	% Received	
Benefits of KPD	**Donors**	**Recipients**
Help multiple recipients	96%	56%
Improved long-term outcomes compared to deceased donation	92%	67%
Matching of highly sensitized participants	64%	61%
Possibility of faster matching than direct donation	56%	67%

Abstract# 1073

In Search of a Better Outcome: Opting Into the Live Donor Paired Kidney Exchange Program

A. J. Vinson[1], B. Kiberd[2], K. J. Tennankore[1], *[1]Nova Scotia Health Authority Division of Nephrology, Departm, Halifax, NS, Canada, [2]Medicine, Dalhousie University, Halifax, NS, Canada*

Purpose: Live donor kidney transplantation is the best option for patients with End-Stage Kidney Disease (ESKD), if a donor is available. However, this may not be the best option if a patient's donor is older and considerably smaller in weight. A patient (A) with a less than ideal donor (Donor A) might enter into a Live Donor Paired Exchange (LDPE) program with the hopes of exchanging for a better-quality organ. A second patient (B) who is in the LDPE may or may not benefit from this exchange with Donor A.

Methods: We performed a medical decision analysis using a Markov model to examine the conditions that favour patient A entering into the LDPE compared to accepting their intended Donor A directly. For the baseline case we examined Patient A and B both aged 45 years, both transplanted after 1 year in LDPE, and a risk of graft loss of 1.6 for Donor A relative to an ideal donor. We also explored circumstances where patient B also benefits by accepting a lower-quality organ from Donor A rather than remaining on the LDPE waitlist.

Results: Under select circumstances a paired exchange could benefit (more life years) both patient A and B. The net benefit (or loss) of entering the LDPE differs by recipient age, donor organ quality, likelihood of patient B being transplanted in LDPE, and likelihood of patient A finding an ideal donor in the LDPE. Under the baseline assumptions, Patient A stands to gain 0.78 LYs if transplanted in LDPE by the end of 1 year compared to undergoing directed transplantation with their current donor. There would also be a gain of 0.47 QALYs. At the same time, Patient B might gain 0.20 LYs (0.65 QALYs) by opting for a lower quality organ from Donor A compared to staying on the LDPE waitlist. In a sensitivity analysis, we varied the relative risk of the Donor A organ and show how this impacted both Patient A and B following transplant through the LDPE versus direct transplant of Patient A with the Donor A kidney, Figure 1.

Conclusions: This study shows there are ways to increase live donor utilization and effectiveness that may require changes to the LDPE process.

Abstract# LB 79

Who Can be Matched via Kidney Exchange?

D. C. McElfresh[1], M. Curry[2], S. E. Booker[3], D. Stewart[3], M. Stuart[3], R. Leishman[4], T. Sandholm[5], J. Dickerson[2], *[1]Applied Mathematics, University of Maryland, College Park, MD, [2]Computer Science, University of Maryland, College Park, MD, [3]United Network for Organ Sharing, Seattle, WA, [4]UNOS, Seattle, WA, [5]Computer Science, Carnegie Mellon University, Pittsburgh, PA*

Purpose: Valuable time and resources are spent screening medically-compatible patients and donors for kidney exchange. Exchanges with tens or hundreds of patients can have thousands of medically-compatible transplants between participating patients and donors. However, only a small number of these transplants can participate in the cyclical or chain-like swaps required by exchange. For example, a patient may have many medically-compatible donors, but cannot join with other patients/donors to form a cycle or chain; this patient is not matchable in the exchange. Exchanges can save valuable resources by focusing on matchable patients, donors, and transplants.

Methods: We study 321 exchanges from the US Organ Procurement and Transplantation Network (OPTN) from 2010-2018. We refer to patient-donor pairs and NDDs as "vertices": we count the number of matchable vertices, which is a fraction

of those with compatible transplants. We also distinguish by patient blood type and sensitization. For each patient, we count the number of compatible donors and matchable donors. Finally, we simulate a match run according to OPTN policy, and count how many vertices and transplants are matched (they would receive a match offer in the exchange).

Results: Most exchanges have over 150 vertices, and about a third of these are matchable. Fig.1A shows the total number of vertices, matchable vertices, and matched vertices (in simulation). Fig.1B shows these numbers by patient sensitization level and ABO. Less than 5% of all highly sensitized patients are matchable, though a large fraction of these are matched by OPTN policy. Most patients have many compatible donors (median=29), but 70% of patients are not matchable. Fig.1C shows a histogram of the number of compatible donors per patient, and Fig.1D shows the number of matchable donors per patient. Among matchable patients, the median number of matchable donors is 3.

Conclusions: Kidney exchanges with hundreds of patients and donors can have thousands of potential transplants, but only a small fraction of these can be matched through cycle- or chain-like swaps. We find that most patients (70%) are not matchable: they cannot participate in exchange. Furthermore, those who are matchable have a small number of matchable donors (median=3). Exchanges can focus their limited resources on matchable patients, donors, and transplants, since all others cannot participate in exchange.

Liver

Liver: Retransplantation and Other Complications

Abstract# 1074

Comparative Outcomes of Endovascular Interventions for Hepatic Artery Stenosis Following Adult Liver Transplantation

S. Desai[1], D. Crabtree[2], A. Parsikia[2], R. Ahuja[1], A. Desai[1], B. Natarajan[1], P. Brady[1], H. Kaul[3], K. Khanmoradi[3], R. Zaki[3], N. Chandolias[3], *[1]Interventional Radiology, Albert Einstein Medical Center - Philadelphia, Philadelphia, PA, [2]General Surgery, Albert Einstein Medical Center - Philadelphia, Philadelphia, PA, [3]Transplant Surgery, Albert Einstein Medical Center - Philadelphia, Philadelphia, PA*

Purpose: There is mounting evidence supporting interventional radiology (IR) treatment for hepatic artery stenosis (HAS) following liver transplantation to improve diminutive graft perfusion and to prevent progression to hepatic artery thrombosis. We aim to evaluate the safety and efficacy of direct hepatic artery interventions versus extrahepatic arterial embolization in the setting of HAS.

Methods: We conducted an electronic search of all hepatic artery angiograms from September 12, 2012 to September 12, 2019, and cross-matched results with orthotopic liver transplant recipients. 91 angiograms for 65 patients were found. Demographics and clinical data were collected. Inclusion criteria consisted of patients with IR intervention within 1 year of transplant and definitive angiographic findings of diminutive hepatic arterial flow secondary to HAS. Decision for mode of intervention was made after intraoperative discussion between IR and transplant surgery physicians.

Results: 36 patients undergoing 48 angiograms were included. 16 patients (average age 58 years; 62% male) underwent direct hepatic interventions and 20 patients (average age 55 years; 65% male) underwent extrahepatic embolization. Preprocedural clinical data shown in Table 1. Interventions for each treatment group illustrated in Figure 1. There was a significant difference in post-operative complications (25% vs 0%, p=0.018). Direct hepatic artery interventions had complications including dissection and in-stent thrombosis with incidence of 6.3% and 18.8%, respectively. There was no significant difference in number of additional procedures or 1- year survival (94% vs 95%).

Conclusions: Extrahepatic arterial embolization provides a significantly better safety profile, with similar efficacy, versus direct hepatic artery intervention when considering treatment for hepatic artery stenosis post orthotopic liver transplant.

Table 1: Preprocedural Clinical Data, Operational Complications and 1-year Outcomes

	Extrahepatic Embolization (*n=20*)	Direct Hepatic Artery Intervention (*n=16*)	p-value

Abstract# 1075

Impact of Social Support, Social Circumstances and Distance from Transplant Center on Post Liver Transplant Outcomes: An Analysis from a Predominantly Rural U.S. Cohort

R. Kaur[1], C. Lavender[1], E. Askew[1], S. Jafri[2], R. Thandassery[1], M. Deneke[1], *[1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]Henry Ford Hospital, Detroit, MI*

Purpose: Social support and social circumstances (SSSC) are critical yet less described entities in post-orthotopic liver transplant (OLT). We aimed to describe SSSC and correlate the nature of social support with post-OLT outcomes in a predominantly rural post-OLT cohort (Arkansas, US). This study also evaluated whether disparities exist between patients' social circumstances and nature of primary support (PS).

Methods: A retrospective cohort study was done on 166 patients who had undergone OLT between January 2014 and September 2019. We attempted to characterize the SSSC of the cohort, which included the nature of PS (spouse vs. non-spouse, number of PS, and if living with PS) and social characteristics (age, gender, ethnicity, employment status, presence of psychiatric diagnosis, drug abuse, and distance of a patient's residence from the transplant center [DTC]). We also correlated nature of PS with post-OLT outcomes.

Results: There were 166 patients composed primarily of males (67.3%), mean age of 55.3 ± 10.8 years, and 86.7% Caucasian. The predominant etiology for liver disease was alcohol (32.5%). Majority of patients (58.4%) had more than 2 people for PS. 64.5% had a spouse as PS and 85.5% lived with their PS. The age at transplant (p=0.32), gender (p=0.65), ethnicity (p=0.83), etiology of liver disease (p=0.37), employment status (p=0.83), history of illicit drug use (p=0.83) and a

psychiatric diagnosis (p=0.38) did not influence the number of PS. These variables didn't influence the type of PS and patient living with PS. Mean DTC (± SD) was 89.0 ± 68.6 miles and 41.6% lived more than 100 miles from the transplant center. The outcomes of OLT analyzed, including post-OLT survival (p=0.81), prolonged hospitalization after transplant (≥ 10 days, p=0.34), 30-day readmission (p=0.83), 1-year readmission (p=0.99), 2-year readmission rates (p=0.87), and rejection at 1 year (p=0.49) and 2 years (p=0.13) did not correlate with number of PS. These outcomes also didn't correlate with the type of PS or the patient living with the PS. Analysis of DTC trended towards worsened post-OLT outcomes including 30-day readmission (p=0.08), number of hospitalizations in 2 years (p=0.08) and rejection in 2 years (p=0.07), but did not correlate with other outcomes like post-OLT survival (p=0.89), prolonged hospitalization (p=0.44), number of hospitalizations in 1 year (p=0.71) and rejection in 1 year (p=0.34).

Conclusions: Established SSSC remains imperative when undergoing liver transplantation. Distance from transplant center appears to be a critical component in this, which may correlate with early readmissions after OLT (30 days), increased readmissions (at 2 years) and rejection on long term follow up (2 years). Future studies may evaluate the role of telemedicine visits on improving these outcomes in predominantly rural cohorts.

Abstract# 1076

Subjective Cognition Among Liver Transplant Recipients

D. Ko[1], M. S. Dietrich[2], K. A. Gifford[3], S. H. Ridner[2], *[1]School of Nursing, Northeastern University, Boston, MA, [2]School of Nursing, Vanderbilt University, Nashville, TN, [3]Department of Neurology, Vanderbilt University Medical Center, Nashville, TN*

Purpose: Regular assessment of cognition is highly suggested to facilitate the early detection and treatment of cognitive impairment in the liver transplant (LT) population. While objective cognitive assessment is a gold standard diagnostic tool for cognitive impairment, it may not be feasible in LT practice since objective measures are often time-consuming. Subjective cognition, patients' self-ratings or caregivers' ratings of cognition for patients, can be used as an alternative to objective assessment. This cross-sectional, single-center study examined correlations between subjective and objective cognition in LT recipients.

Methods: A total 60 pairs of adult LT recipients (median age = 61) and their respective caregivers (median age = 59) participated in this study. The Everyday Cognition (ECog) was used to assess subjective global and domain-specific cognition, by measuring perceived difficulties in performing daily activities. The Repeatable Battery for the Assessment of Neuropsychological Status (RBANS), Trail Making Test parts A&B, Digit Span Backward, and Rey-Osterrieth Complex Figure were used to assess objective global and domain-specific cognition of LT recipients. Agreement between LT recipients and caregivers on subjective cognition was examined using the intraclass correlation coefficient (ICC) and the reliable change index. Correlations between subjective and objective cognition were examined using Spearman's rho correlation.

Results: LT recipients reported few difficulties in performing daily activities. ICCs between LT recipients' and caregivers' subjective cognition scores were rather low (ICC = 0.48 for global score; 0.35-0.56 for domain scores) and agreements within reliable ranges were approximately 50%. Rather weak but significant correlations were found between subjective and objective cognitive scores. Recipients' ECog memory scores were correlated with RBANS immediate and delayed memory scores (r_s = -0.27 and -0.33, both $p < .05$); caregivers' ECog global and attention scores were respectively correlated with RBANS global and attention scores (r_s = -0.27 and -0.33, both $p < .05$).

Conclusions: Findings demonstrate the potential utility of subjective cognition, reported either by recipients and/or caregivers, as a screening tool for expeditiously identifying recipients who are at risk of or experiencing cognitive impairment. Since recipients and caregivers may provide supporting but unique information, clinicians should consider including both of them in cognitive assessment.

Abstract# 1077

Serum Phosphatidylethanol is Superior to Urine Ethyl Glucuronide for Diagnosis of Alcohol Relapse in Liver Transplant Recipients

N. Lim[1], T. Leventhal[1], M. Thomson[1], M. Hassan[1], J. Thompson[1], S. Chinnakotla[2], V. Kirchner[2], T. Pruett[2], R. Kandaswamy[2], V. Humphreville[2], A. Adams[2], J. Lake[1], *[1]Divison of Gastroenterology, Hepatology and Nutrition, University of Minnesota, Minneapolis, MN, [2]Divison of Transplantation, University of Minnesota, Minneapolis, MN*

Purpose: Liver transplantation (LT) for alcohol-related liver disease (ALD) is increasing. The primary issue in these patients is often recidivism, therefore screening for ETOH use is important. Urine ethyl glucuronide (EtG) and serum phosphatidylethanol (PEth) are two highly sensitive and the most common biomarkers used in the diagnosis of ETOH relapse. We compared rates of screening for post-LT ETOH use using PEth and EtG over a 12-month period.

Methods: As part of a prospective quality improvement initiative at our center, patients who receive a LT for ALD have undergone mandatory quarterly screening for ETOH use with urine EtG for the first 12 months after LT since 2016 while any LT recipient undergoes testing if ETOH misuse is suspected. From 1st October 2019 to 30th September, we incorporated quarterly PEth testing into our protocol. Adherence to screening was defined as completion of 4 ETOH tests over the first 12 months after LT. A positive EtG test was defined as EtG>500ng/ml whereas a positive PEth test was defined as PEth>20ng/ml, both levels indicative of significant ETOH use. Positive tests resulted in the activation of a protocol involving the patient's RN coordinator, hepatologist, social worker and chemical dependency resources.

Results: 70 adult patients underwent LT over the study period. 38 patients were transplanted for ALD: 36 patients with ETOH cirrhosis and 2 patients with acute ETOH hepatitis. Median age at LT was 53, 25 (66%) patients were male, 30 (83%) patients were white and median MELD at LT was 29. 31 (81.6%) patients had mental illness prior to LT. Adherence to ETOH screening was 52% for EtG and 87% for PEth, p= 0.0008. There were 2 positive EtG tests compared to 13 positive PEth tests, p= 0.025, over the study period. 7 (19.4%) patients had a positive ETOH test with 4/7 (57.1%) patients adhering to the positive test protocol, although no patients started chemical dependency treatment. Of note, there were 30 positive tests (6 positive EtG and 24 positive PEth) over the study period in 22 patients transplanted prior to October 1st 2019, up to 13 years after LT.

Conclusions: ETOH relapse remains an important issue in a large proportion of patients who undergo LT for ALD, even several years after LT. Screening for ETOH use is significantly higher when using PEth compared to EtG while PEth is significantly better at detecting ETOH relapse. Although identification of ETOH misuse is an essential step, initiation of patients into chemical dependency treatment is a separate, significant challenge.

Abstract# 1078

Biliary Complications Following Adult Deceased Donor Liver Transplantation: Risk Factors and Implications at a High-Volume US Center

A. Matar, K. Ross-Driscoll, L. Kenney, H. Wichmann, J. F. Magliocca, W. H. Kitchens, *Emory Transplant Center, Atlanta, GA*

Purpose: Biliary leaks and anastomotic strictures comprise the majority of biliary complications (BCs) following liver transplantation. Most case series of BCs in adult deceased donor liver transplant are older studies from an era when biliary T-tube usage was common, limiting their application to contemporary transplant practices. Indeed, few large contemporary case series of BCs in adult deceased donor liver transplant (DDLT) recipients exist in the literature. We examined the pre-transplant and intra-operative risk factors associated with BCs at a high-volume tertiary care center and determined the impact of these BCs on their long-term post-transplant outcomes.

Methods: We retrospectively reviewed all adult patients undergoing a DDLT from a donor after brain death at Emory University between January 1, 2015 and December 31, 2019.

Results: 647 patients underwent DDLT during the study period with a median follow-up of 2.5 years. A total of 27 bile leaks (4.2%) and 69 biliary strictures (10.7%) were detected. Whereas bile leaks were detected a median of 4 days after transplant (range: 0-65 days), biliary strictures were detected a median of 139 days after transplant (range: 5-1060 days). Biliary complications are often defined as presenting early (occurring <30 days post-transplant) or late (occurring >30 days post-transplant). Of patients who developed a bile leak, only 11.1% presented late, whereas 87% of biliary strictures presented late. Risk factors associated with biliary strictures included alcoholic cirrhosis as the etiology of liver failure. Risk factors for

bile leaks included viral hepatitis as etiology of liver failure and MELD exception points. Utilization of biliary stents was strongly associated with development of both bile leaks and biliary strictures (RR= 2.25, 95% CI 1.39-3.57). In our series, 77% of biliary leaks were managed surgically through either a revision of the biliary anastomosis (42.3%) or conversion to a Roux-en-Y hepaticojejunostomy (19.2%). "Early" bile leaks diagnosed prior to POD 14 (n = 19) were exclusively managed surgically (100%), while "late" biliary leaks (n = 7) were managed primarily endoscopically (71%). In contrast, the vast majority of anastomotic strictures were definitively managed endoscopically (95.7%), with a mean of 3.2 procedures per patient. Post-transplant, biliary leaks significantly increased the risk of subsequent episodes of acute rejection (RR= 2.47, 95% CI 1.04-5.93) but did not impact patient survival. In contrast, biliary strictures did not impact acute rejection rates but was associated with a significantly reduced patient survival at one- and four-years post-transplant (RR= 5.70, 95% CI 2.4-13.5).

Conclusions: BCs are a major source of morbidity and mortality following DDLT. Comprehensive analyses from high-volume centers are needed to identify risk factors for BCs to facilitate improved outcomes.

Abstract# 1079

Predictive Factors of the Hepatic Artery Thrombosis in Liver Transplantation Through the Analysis of Donor Characteristics

M. M. Pascale[1], G. Moschetta[2], G. Bianco[2], F. Frongillo[2], E. Nure[2], F. Giovinazzo[2], S. Agnes[2], *[1]General Surgery and Liver Transplant Unit, Fondazione, Roma, Italy, [2]General Surgery and Liver Transplant Unit, Fondazione "Policlinico A. Gemelli" UCSC - Rome, Roma, Italy*

Purpose: Hepatic artery thrombosis (HAT) is one of the most severe complications after liver transplantation. It is treated as soon as possible to avoid irreversible time-dependent graft dysfunction.The early finding of arterial complications can lead to an improvement in transplant outcome, through specific clinical surveillance for high-risk cases.The detection of predictive factors for HAT is thus crucial for post-transplant management, with significant repercussions on the survival of the graft and the patient.This work aims to investigate the relationship of donor-related factors with the onset of HAT after liver transplantation.

Methods: Consecutive liver transplants performed in our Center from November 2006 to July 2020 were retrospectively investigated.The donor parameters considered as predictive factors for HAT were 14: age, gender, body mass index (BMI), alcohol or tobacco abuse, diagnosis of diabetes, hypertension, dyslipidaemia, pre-mortem hypotension or cardiac arrest, pre-mortem use of high-dose (nor)epinephrine, cause of death, cold ischemia time (CIT).The donors were divided according to the post-transplant development of HAT.Categorical variables were compared with the Pearson chi-square test, while continuous variables were analyzed with Student's T test.Predictive features were analyzed with a binary logistic regression

Results: In the considered period, 359 liver transplants were performed in our center. The incidence of HAT in the population was 4.1%. The recipients, grouped according to the detection of HAT, showed no demographic or clinical differences. Examining the factors related to the donor, a relationship of HAT was found with death from anoxia (p=0.036), with the over-50 age (p=0.037), with a positive history of cardiovascular disease (p=0.044) or diabetes mellitus (p=0.038).Multivariate analysis of significant parameters showed a strong correlation with post-transplant development of HAT (p <0.0001).

Conclusions: HAT is one of the most dreaded complications after liver transplantation. It can result in a primary non-function of the graft in the absence of prompt treatment.The development of predictive factors is a good strategy to optimize the search for arterial complications.Our data indicated a good reliability of the donor's cardiovascular risk factors (age over 50, heart disease, diabetes mellitus, death from anoxia) on the transplant outcome, more reliable when present together.Through the transplant, the graft is moved in the recipient together with its pre-existing history.

Abstract# LB 81

Hepatic Artery Thrombosis and Liver Transplantation: Patient Management and Candidate Selection for Re-transplantation

H. Fernandez, A. Wall, A. Gupta, E. Martinez, J. Bayer, G. McKenna, N. Onaca, R. Ruiz, C. Spak, G. Testa, *Baylor University Medical Center, Dallas, TX*

Purpose: Hepatic artery thrombosis (HAT) is a severe complication in liver transplantation (OLTX). Re-OLTX for patients with HAT has been met with controversy due to uncertain long-term outcomes. Patient selection for re-OLTX has not been defined.

Methods: This is a retrospective review of patients undergoing OLTX between 1985-2016. A total of 4172 OLTX were performed, 265 identified with HAT. Recipient demographics, complications, allograft/patient survival, and re-OLTX outcomes were analyzed. OLTX cases were then divided into: Group 1 (HAT <28 days), Group 2 (28 days-1year) and Group 3 (> 1 year).

Results: Graft loss rate for patients with HAT within the first year of OLTX was 67.3%, while the mortality rate was 80.2%. Group 1 patients most commonly presented with sepsis, while Group 3 patients mainly presented with biliary complications. On multivariate analysis, recipient age and antibiotic usage were significant in patient survival. HAT patient survival was lower than non-HAT patients, with Group 1 patients having the lowest patient survival within the first two years (Figure 1). Patient survival for re-OLTX was similar for patients undergoing re-OLTX for indication of HAT, versus all other causes (Figure 2). Group 1 patient survival was lower at all time points compared to all other groups for patients with or without re-OLTX. Group 2 patient survival at 1 month, 3 months, 1 year were similar with and without re-OLTX, however, the 5-year survival with re-OLTX was significantly lower. Group 3 patients with and without re-OLTX had similar survival at all time points.

Conclusions: Graft and patient survival are critically dependent on the time of HAT diagnosis, and the entire clinical picture should be considered prior to re-OLTX, as this may prove detrimental to patient survival. Sepsis, antibiotic therapy, and recipient age are important when considering re-OLTx in Group 1 patients. Long-term survival of Group 2 patients should be considered when discussing re-OLTX in this subset of patients. Group 3 patients should be treated with non-surgical management. In the face of donor shortage, it is imperative to determine the role of re-OLTX in management of HAT patients.

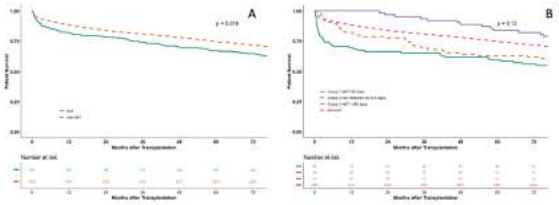

Figure 1. Patient survival a) HAT (all groups) vs. non-HAT patients b) overall survival of Group 1/2/3 vs. non hat patients

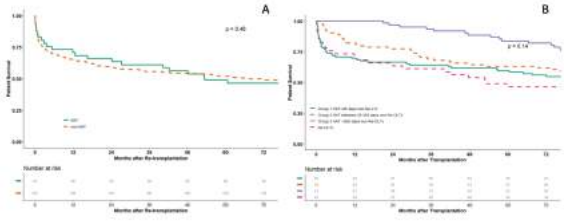

Figure 2. Patient survival a) re-OLTX for HAT vs. all other causes b) Group 1/2/3 non re-OLTX vs. re-OTLX patients

Liver

Liver: Kidney Issues in Liver Transplantation

Abstract# 1080

Development of Novel Multivariable Logistic Regression Model for Predicting Acute Kidney Injury After Liver Transplantation

H. Chen, Y. Nie, Q. Zhao, X. He, *Organ Transplant Center,, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*

Purpose: Acute kidney injury (AKI) is a common early complication after liver transplantation, but there are no related predictive tools or models at present. The purpose of this study is to find out the risk factors related to the occurrence of AKI and establish a predictive model.

Methods: A retrospective analysis of patients with end stage liver disease who received liver transplantation in Organ Transplant Center, The First Affiliated Hospital of Sun Yat-sen University from 2016 to 2017 was performed. Univariate and multivariate logistic regression were used to identify factors associated with the occurrence of AKI, and a diagnostic nomogram was generated.

Results: A total of 223 patients with complete medical records were included and 111 patients suffered AKI after transplantation, accounting for 49.8% of the included cases. Univariate and multivariate analysis confirmed that blood lactate at the end of operation($P < 0.001$), Child-Pugh grading($P < 0.001$) and intraoperative urine output ($P = 0.005$) of recipients as well as age of donor($P = 0.02$) were independent predictors of AKI. A diagnostic nomogram with a c-statistic 0.803 was established.

Conclusions: Independent predictors of the occurrence of AKI in patients after liver transplantation include blood lactate at the end of operation, Child-Pugh grading and intraoperative urine output of recipients as well as age of donor. This is the frst study to develop a nomogram exclusively for AKI after liver transplantation that may predict occurrence in future studies.

Abstract# 1081

Non-Alcoholic Fatty Liver Disease in Non-Liver Transplant Patients

R. Claudio[1], C. Conceicao[2], K. Robichaux[2], A. Kumar[1], J. Buggs[3], N. Kemmer[4], *[1]Morsani College of Medicine, University of South Florida, Tampa, FL, [2]Honors College, University of South Florida, Tampa, FL, [3]Transplant Surgery, Tampa General Hospital, Tampa, FL, [4]Transplant Hepatology, Tampa General Hospital, Tampa, FL*

Purpose: The global prevalence of non-alcoholic fatty liver disease (NAFLD) is rising at an alarming rate, driven in large part by an increased incidence of diabetes and obesity. NAFLD is currently the number one cause for liver transplantation in the U.S. It has also been shown to have effects on patients undergoing transplants for other organs such as kidneys and pancreas. The purpose of our study was to evaluate the prevalence of fatty liver in non-liver transplant patients, looking particularly at kidney transplants.

Methods: We conducted a single-center retrospective cohort study of patients undergoing kidney transplants from January 2015 to December 2019. Patient data were obtained from the United Network for Organ Sharing (UNOS) as well as our hospital's electronic medical record system. Patient records were reviewed at the time of transplant to one year after transplant. Patients under 18 years of age at the time of transplant were excluded from our study. The presence of fatty liver was determined via radiological imaging. Our primary endpoint was the prevalence of NAFLD outside of known end-stage liver disease in kidney transplant patients.

Results: Of the 1300 kidney transplant patients, 149 (11.5%) were found to have a fatty liver noted before or after their initial kidney transplant. Abdominal ultrasound was the primary imaging technique utilized for diagnosis. The mean age of patients was 53 years for NAFLD and 51 years for non-NAFLD patients. Of the 149 patients with a fatty liver, 30 (20.1%) underwent a living donor transplant, 144 (96.6%) had diabetes and only 17.4% of NAFLD patients received a hepatology consult.

Conclusions: This study emphasized the need to diagnose and understand post-transplant outcomes for NAFLD patients in the kidney transplant population as well as increase efforts to ensure patients with fatty liver receive consultations from specialists/hepatologists. With NAFLD currently being the number one indication for liver transplants, undiagnosed NAFLD patients are at risk of developing health complications if left untreated and may require a liver transplant.

Abstract# 1082

A Significantly Shorter Waiting Time to Subsequent Kidney Transplant After Liver Transplant by Using Safety Net Policy

P. Homkrailas, S. Bunnapradist, *Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA*

Purpose: In August 2017, a new simultaneous liver-kidney transplant (SLK) allocation policy and medical eligibility criteria were introduced. These criteria aim to avoid dual organ transplant in patients who may recover their native kidney function. For patients whose renal function fail to recover by 60 days after liver transplant, a "safety net" policy has been introduced to increase the priority of liver transplant recipients on kidney waiting list. Here we compared waiting time to kidney transplant among patient whose develop acute kidney injury (AKI) requiring dialysis during liver transplant peri-operation before and after safety net policy.

Methods: The OPTN/UNOS data from 1987-2020 of patient who were listed and had received liver transplant alone which developed AKI requiring dialysis within 30 days before or after liver transplant were included. Patients who were listed for SLK were excluded. Study populations were grouped according to safety net priority offer into before and after safety net policy.

Results: A total of 8,617 patients who had received liver transplant were listed for kidney transplant. Five hundred and twenty-six patients who had received dialysis within 30 days before or after liver transplant were listed for kidney transplant. There were 446 patients listed before safety net policy and 80 patients listed after safety net policy which 255 (57.2%) and 43 (53.8%) of them subsequently received kidney transplant, respectively. There were 280 patients (62.8%) and 80 patients (100%) listed for subsequent kidney transplant within 1 year before and after safety net policy, respectively. Seventy-three patients (16.4%) died while waiting for kidney transplant before safety net policy and 4 patients (5.0%) died while waiting after safety net policy. Before safety net policy, patients were listed for kidney transplant 255 (0-2472) days after liver transplant compared to 170 (0-363) days after safety net policy ($p=0.06$). Median waiting time to kidney transplant were 1,006 days before safety net policy and 241 days after safety net policy ($P<0.001$). There were 65.1% and 90.7% of subsequently transplanted patients receiving kidney transplant within 1 year before and after safety net policy, respectively ($p<0.001$).

Conclusions: After a safety net policy was introduced, patients who deemed a candidate for kidney transplant were listed within 365 days to take an advantage of safety net priority offer. None of them were listed after 365 days post liver transplant. Waiting time to kidney transplant after safety net policy were significantly shorter compared to before safety net policy with a significantly higher proportion of patients receiving kidney transplant within 1 year.

Abstract# 1083

Perioperative Terlipressin Therapy Reduces the Risk of Acute Kidney Injury Post-Living Donor Liver Transplantation - A Systematic Review and Meta-analysis

A. V. Kulkarni, H. V. Tevethia, M. Sharma, P. Kumar, N. P. Rao, N. D. Reddy, *Hepatology and Liver Transplantation, Asian Institute of Gastroenterology, Hyderabad, India*

Purpose: Acute kidney injury (AKI) after liver transplantation precludes calcineurin inhibitors' therapy and is associated with poor outcomes. Terlipressin (Tp) has mortality benefit in pre-transplant patients with AKI; however, the data on perioperative use of Tp and its effect on post-transplant outcomes has not been systematically reviewed.

Methods: A comprehensive search of electronic databases from 2000/01/01 to 2020/10/31 was performed. Studies reporting the use of Tp in the perioperative period were included. We considered the random model risk ratio (RR) as the primary result unless I^2<50%. The primary aim was to assess the risk of AKI post-transplant. The secondary was to assess the need for renal replacement therapy (RRT), vasopressors, blood loss during surgery, hospital stay, and in-hospital mortality.

Results: A total of nine studies reporting 711 patients undergoing LDLT were included for analysis. Males-83%. Tp was given for a mean duration of 53.44±28.61 hours post-surgery. Tp reduced the risk of post-transplant AKI by 60% (RR-0.6; 95%CI-0.44-0.8; p=0.001) among 166 patients who received Tp compared to 269 control (C) patients among four studies (I^2=0; p=0.45) (Fig. A). Need of RRT was similar in Tp (n=135) and C (n=238) group (RR-0.75 (0.35-1.56); p=0.44) among 3 studies (I^2=0; p=0.75). Tp therapy reduced the risk of vasopressor use by 33% (0.24-0.47; p<0.001) among six studies (I^2=3.12; p=0.39), which reported 240 patients in the Tp group and 342 in the control group. (Fig. B) Blood loss was similar in both groups (-302.12 ±215.32; p=0.16) among four studies (I^2=43.16; p=0.15) which reported. There was no mortality benefit with Tp [RR-1.08 (0.48-2.42);p=0.84)] among two articles, which reported in-hospital mortality among 147 and 242 patients in T and C groups, respectively. Mean hospital stay was also similar in both groups [-0.94 (-2.24 to 0.35) ;p=0.15] among 4 studies (I^2=52.5; p=0.09) which reported hospital stay among 424 patients. Mean ICU stay was also similar in both the groups [0.08 (0.42 to 0.18) ;p=0.84] among 4 studies (I^2=82.83; p<0.001) which reported 465 patients. Only one study reported adverse events (bradycardia) to Tp.

Conclusions: Perioperative Tp therapy reduces the risk of post-transplant AKI and the need for vasopressor treatment. However, its use is not associated with a reduction in hospital stay, need for RRT, or mortality. Future extensive, randomized studies are required to assess the beneficial role of Tp on post-transplant outcomes.

Abstract# 1084

Comparison of Allograft Outcomes in SLK Transplant Patients with and without ESLD: A UNOS Database Analysis

P. Kyriazis, H. Patel, P. Nissaisorakarn, F. Cardarelli, N. Agrawal, *Transplant Division, Beth Israel Deaconess Medical Center, Boston, MA*

Purpose: Simultaneous liver and kidney transplants (SLKT) have started to gain ground in the treatment of liver disease with associated acute or chronic kidney disease. In certain metabolic liver diseases with resultant kidney failure, SLKT is performed to help improve kidney graft survival, when the liver function is seemingly normal. Primary hyperoxaluria (PH), a rare autosomal recessive liver disease that leads to kidney failure and is the most common cause of metabolic liver disease treated with SLKT.

SLKT is known to provide immunological protection for kidney allograft, as compared to kidney alone, for unclear reasons. In this analysis, we compared the allograft survival in patients with and without End-Stage Liver Disease and explored whether this immune tolerance is enhanced by the presence of ESLD pre-transplant, similar to how bone marrow transplant patients undergo a preparative regimen to create an environment conducive to long-term engraftment.

Methods: We conducted a retrospective analysis of UNOS database (2000-2019) among SLKT recipients who had a diagnosis of Oxalosis or Cirrhosis. To prevent the selection bias, only younger patients with age<40 years were selected for the study in both groups. Graft survival time and graft failure rate were measured using Kaplan Meier analysis.

Results: Of the total of 365 patients, 116 (31.8%) were in the Oxalosis group and the remaining 249 were in the cirrhosis group. Patients in the Oxalosis group were younger, had lower BMI, higher rate of delayed graft function (48.3% vs 26.9%, p<0.001), increased dialysis vintage time and less preemptive transplants (Table 1). There was no difference in acute rejection rates, death censored kidney graft survival at 1st, 3rd, 5th and 10th year between the groups.

Conclusions: Among the SLKT recipients, young patients with liver cirrhosis had similar graft and patient outcomes compared to patients with metabolic liver disease, who otherwise had normal liver function pre-transplant. This could be due to shorter ESRD duration in cirrhosis patients pre-transplant. The presence of ESLD pre-transplant does not appear to affect the rate of allograft rejection in SLKT recipients.

Figure 1: Kaplan Meier death censored kidney graft survival

Abstract# 1085

The Combined Effects of Simultaneous Portal Vein Thrombosis and Renal Dysfunction in Liver Transplant Recipients

M. Molinari[1], C. F. Carillo[2], D. Dongling[1], D. Jorgensen[1], S. Dharmayan[1], C. Kaltenmeier[1], H. Liu[1], J. Behari[1], V. Rachakonda[1], S. Ganesh[1], C. Hughes[1], A. Tevar[1], H. Al Harakeh[1], B. Emmanuel[1], A. Humar[1], R. Bataller[1], [1]*University of Pittsburgh Medical Centre, Pittsburgh, PA,* [2]*Medicine, University of Pittsburgh Medical Centre, Pittsburgh, PA*

Purpose: Simultaneous portal vein thrombosis (PVT) and renal dysfunction (RD) have unknown effects after liver transplant (LT). We analyzed the outcomes of patients with simultaneous PVT/RD after LT for nonalcoholic steatohepatitis (NASH) and for alcoholic liver disease (ALD), the two most common indications for LT in the US.

Methods: Data from the UNOS Star files were used to identify adult recipients (≥18 years) of deceased donors LT with NASH or ALD. Patients with ABO incompatibility, non-hepatocellular carcinoma malignancies, partial grafts, and multi-visceral transplants were excluded. RD was defined as serum creatinine ≥1.5 mg/dL or the need for dialysis. Student's t-test, chi-square, ANOVA, Kaplan-Meier, log-rank test, Cox regression, logistic and Poisson regression were used for statistical analyses.

Results: Between 2006 and 2016, the percentage of patients undergoing LT with PVT, RD, and simultaneous PVT/RD went from 7.2% to 11.3% (P<0.001), from 33.8% to 39.2% (P<0.001) and from 2.4% to 4.5% (P<0.001) respectively. Recipients with simultaneous PVT/RD had a 30-days, 90-days and at 1-year mortality of 6.4%, 9.8% and 16.9% in comparison to 2.1%, 3.8% and 6.5% in patients without PVT or RD (P<0.001). The 5-year survival of recipients without PVT or RD was 82.1% (95% CI 80.9-83.3). For patients with RD alone, the 5-year survival was 75.5% (95% CI 74.3-77.5), for patients with PVT alone was 74.8% (95%CI 71.9-77.9) and for patients with simultaneous PVT/RD was 71.1% (95% 70.1-73.9) (All pairwise comparisons: P<0.05). Cox regression analysis showed that PVT, RD and simultaneous PVT/RD were independent risk factors after adjusting for recipient age, sex, ethnicity, diabetes, BMI, MELD, history of previous abdominal surgeries, ascites, TIPSS, spontaneous bacterial peritonitis, donor age, and year of transplantation. The adjusted hazard ratio for RD was 1.45 (95% CI 1.30-1.61; P≤0.0001), for PVT was 1.29 (95% CI 1.05-1.58; P=0.012), and for simultaneous PVT/RD was 2.11 (95% CI 1.73-2.56; P≤0.0001).

Conclusions: The number of patients undergoing LT for ALD or NASH with PVT, RD, and simultaneous PVT/RD has increased over time. PVT, RD and simultaneous PVT/RD are associated with increased perioperative mortality and inferior long-term survival. The effects of simultaneous PVT/RD are more pronounced in patients with NASH than in LT recipients with ALD

Abstract# 1086

Combined Liver-Kidney Transplantation in Adults With End-Stage Liver Disease: Risk Factors in Patients with Chronic Kidney Disease Stages 3-5, Not on Maintenance Dialysis

A. Santos, E. Bueno, M. Leghrouz, *University of Florida, Gainesville, FL*

Purpose: We aimed to identify the risk factors for combined liver-kidney transplantation (CLKT) vs. liver transplantation alone (LTA) in end stage liver disease (ESLD) patients with estimated glomerular filtration rate (eGFR) <60 ml/.min, not on dialysis.

Methods: Using OPTN data, we studied adult ESLD patients who received deceased-donor CLKT [N=2016 (12.9%] or LAT [N=13,588 (87.1%)] in July 2002-Mar 2016 with a 4-point modification of renal disease (MDRD) equation-estimated glomerular filtration rate (e-GFR) of below 60 ml/min (stratified into CKD stage 3: 30-59 ml/min, CKD stage 4: 15-39 ml/min, and CKD stage 5: <15 ml/min) and not on maintenance dialysis (NOD). The outcome of the study was CLKT or LAT. We reported odds ratio (OR) and 95% confidence interval (CI) for CLKT vs. LTA associated with recipient, donor, and clinical variables.

Results: Out of 15, 604 CLKT and LTA recipients with MDRD-eGFR <60 ml/min. 8,784 (56.3%) had CKD stage 3; 4,916 (31.5%) had CKD stage 4; and 1,891 (12.1%) had CKD stage 5. CKD stages 5 and 4 at WL and transplant were the strongest risk factors for CLKT vs. LTA (FIG.1). Strong non-renal risk factors for CLKT vs. LTA were WL-time, Black recipients, liver re-transplant, and DM (**TAB. 1**). Factors associated with stronger likelihood of LTA vs. CLKT were WL-MELD >35, donor age>60 years, WL-MELD 31-35, female recipient's sex, and hepatocellular carcinoma (**FIG. 1 & TAB 1**). Transplant center volume rank in the middle or highest tertile was associated with a lower likelihood of CLKT vs. LTA than the lowest tertile (**FIG. 2, TAB. 1**).

Conclusions: Advanced CKD, waitlist time, AA ethnicity, previous liver transplant and DM are strong risk factors favoring CLKT vs. LTA.

Risk Factor	95%CI LL-UL	OR

Abstract# 1087

Obesity is a Risk Factor for Progression to Kidney Transplant Waitlisting After Liver Transplantation

B. Shelton[1], B. Orandi[1], K. Olthoff[2], E. Pomfret[3], K. Forde[2], D. Sawinski[2], M. Gray[1], N. Ascher[4], J. Locke[1], *[1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Colorado School of Medicine, Aurora, CO, [4]University of California San Francisco, San Francisco, CA*

Purpose: Non-alcoholic steatohepatitis (NASH) has emerged as a leading cause of cirrhosis, and obesity-associated comorbid conditions, including renal disease have become more prevalent. Obesity predisposes the kidney to hyperfiltration injury, potentially impairing recovery from acute kidney injury. Prospective identification of patients at risk for renal dysfunction has been limited by poor performance of renal function estimating equations among cirrhotics. To better understand the relationship between obesity at time of liver transplantation and likelihood of renal disease progression, we examined likelihood of listing for kidney transplantation (KT) after liver transplant alone (LTA) by obesity class.

Methods: Utilizing data from SRTR (2005-2018), 68,607 LTA recipients were studied. Fine and Gray competing risks models were used to analyze the association of obesity at time of LTA with likelihood of subsequent listing for KT.

Results: 27.4% of LTA recipients were obese (BMI≥30kg/m2) and were 10% more likely to require listing for KT following LTA compared to non-obese (aHR: 1.10, 95%CI: 1.01-1.20). This risk increased with obesity class, with no significant risk difference among recipients with Class I obesity but 37% higher risk among Classes II and III (BMI: ≥35kg/m^2) recipients compared to non-obese (aHR: 1.37, 95%CI: 1.17-1.56). Moreover, recipients with Classes II and III obesity at time of LTA compared to non-obese were 57% more likely to be listed for KT within their first year post-LTA (aHR: 1.57, 95%CI: 1.18-2.10).

Conclusions: These findings suggest obesity was a risk factor for failure of renal recovery and/or renal disease progression post-LTA and may further confound identification of renal dysfunction and/or prediction of renal recovery among cirrhotics.

Table 1. Adjusted risk of listing for kidney transplant within various times since transplant (competing risks model)

	One year		Three years		Five years

Abstract# LB 82

Chances of Renal Recovery in Liver Only Transplant Recipients Who Were Eligible for Simultaneous Liver-Kidney Transplant

J. Cui[1], A. Spann[2], A. Shingina[2], H. M. Schaefer[3], J. C. Slaughter[4], S. Alexopoulos[5], M. Izzy[2], *[1]Internal Medicine, Vanderbilt University Medical Center, Nashville, TN, [2]Gastroenterology, Hepatology, and Nutrition, Vanderbilt University Medical Center, Nashville, TN, [3]Nephrology, Vanderbilt University Medical Center, Nashville, TN, [4]Biostatistics, Vanderbilt University Medical Center, Nashville, TN, [5]Hepatobiliary Surgery and Liver Transplantation, Vanderbilt University Medical Center, Nashville, TN*

Purpose: Progressive decline in renal function is common among patients with end-stage liver disease. Liver transplant (LT) candidates can often develop severely impaired renal function which prompts the consideration of simultaneous liver kidney transplantation (SLKT). In 2017, the United Network for Organ Sharing (UNOS) recommended SLKT in patients with GFR <30 ml/min after being <60 ml/min for at least 90 days. This study aims to assess the post-LT renal recovery in patients who met UNOS criteria for SLKT, yet received liver alone.

Methods: We performed a retrospective records review of adult patients who underwent LT between 1/1/2009 to 12/31/2018 at a North American Center. Liver only recipients whose last GFR before LT was <30 ml/min after being <60 ml/min for more than 90 days were included. Demographic, clinical, and laboratory data were collected. Partial recovery was defined as post-LT GFR increase to 30-60 ml/min and full recovery was defined as increase to >60 ml/min.

Results: Of 800 patients who underwent LT during the observation period, 123 patients had GFR <30 ml/min pre-LT and of them only 34 had GFR <60 ml/min preceding LT by 90 days or longer. Median age was 63 years. Females constituted 59% of the cohort. Following liver transplant, 20 patients (59%) had partial recovery and 10 patients (29%) had full recovery within a median of 6 and 61 days, respectively. Among baseline characteristics including comorbidities, abnormal radiologic appearance of the kidneys pre-LT, reflective of chronic disease, was the only predictor of lack of recovery (p=0.03). All initial immunosuppressive regimens were tacrolimus-based. On last follow up after a median of 4.8 years, 15 patients (44%) still had GFR >30 ml/min while 19 (56%) patients were on dialysis, awaiting kidney transplant, or received kidney transplant. Patients with pre-LT unrecovered AKI or HRS had the highest likelihood of recovery on last follow up (OR 4.7, p=0.03).

Conclusions: LT candidates who meet UNOS criteria for SLKT yet undergo LT only still have a remarkably high chance for post LT renal recovery, approaching 90% on short-term. A large proportion of patients can sustain recovery long-term. The use of the 2 to 12 month Safety Net for kidney transplant post-LT is an important consideration for those with potentially recoverable renal dysfunction pre-LT as opposed to SLKT.

Liver: Cirrhosis - Portal Hypertension and Other Complications?

Abstract# 1088

Transplant-free Survival in Alcohol-related Liver Disease (ALD) Patients Presenting with First Evidence of Ascites

K. Fahoum[1], N. T. Shen[2], E. Basu[1], J. Lee[3], A. Kaplan[2], A. Salajegheh[4], R. Rosenblatt[2], A. Jesudian[2], C. Lucero[2], B. Fortune[2], M. M. Safford[5], R. S. Brown[2], *[1]Medical College, Weill Cornell Medicine, New York, NY, [2]Gastroenterology and Hepatology, Weill Cornell Medicine, New York, NY, [3]Population Health Sciences, Weill Cornell Medicine, New York, NY, [4]Psychiatry, Weill Cornell Medicine, New York, NY, [5]General Internal Medicine, Weill Cornell Medicine, New York, NY*

Purpose: The development of ascites is a poor prognostic sign for patients with cirrhosis. The factors associated with transplant-free survival at initial presentation with ascites in patients with alcohol-related liver disease (ALD) are currently unknown. We thus aimed to identify these factors in order to direct limited resources to those patients with ALD at highest risk of needing transplant or dying.

Methods: Adult patients with ascites in the "Evaluating Alcohol Use in Alcohol-related Liver Disease prospective cohort study" (NCT03267069 clinicaltrials.gov) were identified from 2016-2020. Transplant status and death were tracked in patients' charts from time of enrollment through June 2020. Demographic, clinical, and laboratory factors at initial ascites presentation were identified as potential predictors of transplant-free survival. Fisher's exact test and Wilcoxon rank sum test were conducted to test the association between predictors and transplant/death status. Cox proportional hazards models were used to identify significant predictors of transplant/death status. Predictors with p<0.1 in the univariable model were included in the final model.

Results: A total of 98 patients were identified. Median (IQR) follow up time was 2.6 years (1.5 - 4.6). By last follow up, 45/98 (46%) had either been transplanted or died. Of patients that survived without transplant, 45% had resolution or clinical improvement of ascites. Variables associated with transplant/death were non-employed status, presence of encephalopathy, number of portal hypertension complications, presence of cirrhosis on histology (p<0.01) and male sex, BMI, Model for End-stage Liver Disease (MELD) score, Maddrey's Discriminant Function, lower ALT, higher total bilirubin, higher INR, and presence of hepatitis on histology (p<0.05). In the multivariable Cox proportional hazards model, younger age (HR 0.92, p<0.05), higher BMI (HR 1.12, p<0.01), and higher comorbidity burden (HR 2.32, p<0.005) were associated with increased likelihood of transplant/death. Mean age was significantly different when outcome groups were separated into transplant (53.2), death (62.8), and transplant-free survival (57.9) (p<0.05).

Conclusions: Higher comorbidity index and BMI at time of initial presentation with ascites were associated with increased likelihood of transplant/death. While younger age appears to be associated with increased likelihood of transplant/death, this likely reflects the younger population of patients that are selected for transplant, as mean age of transplant patients was the lowest of all groups.

Abstract# 1089

Identification of Molecular Markers for Liver Cirrhosis by Single-nucleus Rna Sequencing

C. Kuscu[1], C. Kuscu[1], M. Akram[2], A. Shetty[3], D. G. Maluf[4], J. Eason[1], V. Mas[5], *[1]Surgery, James D Eason Transplat Institute, Memphis, TN, [2]Surgery, Center for Biomedical Informatics, Memphis, TN, [3]Surgery, Institute for Genome Sciences, School of Medicine, Baltimore, MD, [4]Surgery, Program in Transplantation University of Maryland, Baltimore, MD, [5]Surgery, Division of Surgical Science University of Maryland, Baltimore, MD*

Purpose: Non-alcoholic fatty liver disease (NAFLD) is characterized by metabolic syndrome and the accumulation of fat in the liver cells (hepatocytes) leading to inflammation and potentially cirrhosis. Hereby, we assessed the use of single-cell/nucleus genomics to identify the molecular and cellular mechanisms of fibrosis/cirrhosis caused by NASH at single cell resolution.

Methods: Single cell or nucleus sequencing identifies the genomic and transcriptomics information from individual cells using next-generation sequencing (NGS) platform. We isolated single nuclei from fresh-frozen (FF) samples including normal, fatty, fibrotic and cirrhotic liver tissues (NASH cirrhosis). We used 10x Genomics Chromium Platform and generated data in their Cell-Ranger Pipeline. Unsupervised "Seurat" package was used to generate cluster and cell identification.

Results: We identified two different hepatocyte clusters in fatty liver samples. Furthermore we observed a significant decrease of healthy number of hepatocytes in NASH and cirrhotic samples due to the replacement of epithelial cells with fibrotic cell. Replacement of those cells has been correlated with the elevated level of CACNA1C, CFTR, COL4A1, and COL4A2. Interestingly, there was a distinct class of unknown cells in cirrhotic livers that deserve further investigation (Fig 1).

Conclusions: In this study, we identified different cell/nucleus clustering on the liver sample type, ranging from normal to cirrhotic, highlighting the cellular shift occurring during different stages of liver disease leading to NAFLD-Cirrhosis

Abstract# 1090

Algorithms to Identify Alcoholic Hepatitis Hospitalizations in Patients with Cirrhosis

S. Panchal[1], D. Kaplan[2], D. Goldberg[3], N. Mahmud[2], *[1]Medicine, Hospital of the University of Pennsylvania, Philadelphia, PA, [2]Gastroenterology, Hospital of the University of Pennsylvania, Philadelphia, PA, [3]Gastroenterology, University of Miami Miller School of Medicine, Miami, FL*

Purpose: With the rising proportion of patients receiving liver transplantation for alcoholic hepatitis, it is important to identify methods of ascertaining hospitalizations with alcoholic hepatitis to facilitate research using large administrative databases.

Methods: This was a retrospective study using data from patients with cirrhosis identified between 2008 and 2016 in the Veterans Health Administration. Hospitalization data including admission laboratory data and administrative codes were obtained for each patient. We randomly sampled charts from patient hospitalizations with abnormal liver tests or codes for alcoholic liver damage or acute hepatitis. Charts were manually adjudicated for the presence or absence of alcoholic hepatitis as the gold standard using published criteria. Several *a priori* algorithms were then evaluated to determine the positive predictive value (PPV) of each, as well as the 95% confidence interval (CI).

Results: A total 355 randomly sampled patient hospitalizations were manually adjudicated, 36% or which were determined to have alcoholic hepatitis. The median age was 57 years (interquartile range [IQR] 53, 62), 96.9% male, with 78.3% alcohol or alcohol plus hepatitis C virus as the primary etiologies of liver disease. Evaluating four series of algorithms (**Table**), a combination of a diagnostic code for alcoholic hepatitis and supportive laboratory findings yielded ≥90% PPV, with >95% PPV using optimized laboratory cut points.

Conclusions: We have identified algorithms to identify alcoholic hepatitis hospitalizations with extremely high PPV. These may be used in retrospective studies incorporating large administrative datasets.

Algorithm	Algorithm Positive (N)	PPV (%)	95% CI
1 – Abbreviated Clinical Criteria			
AST >50 & <400, ratio>1.5, bilirubin>3	214	51.9	45.0 - 58.7
AST >110 & <435, ratio>1.5, bilirubin>3	132	61.4	52.5 - 69.7
AST >110 & <435, ratio>2.0, bilirubin>3	112	64.3	54.7 - 73.1
AST >110 & <435, ratio>2.0, bilirubin>5	90	70.0	59.4 - 79.2
2 – ICD Criteria (code for alcoholic hepatitis)	99	71.7	61.8 - 80.3
3 – Abbreviated Clinical OR ICD Criteria			
AST >50 & <400, ratio>1.5, bilirubin>3	243	49.0	42.5 - 55.4
AST >110 & <435, ratio>1.5, bilirubin>3	178	57.3	49.7 - 64.7
AST >110 & <435, ratio>2.0, bilirubin>3	163	60.1	52.2 - 67.7
AST >110 & <435, ratio>2.0, bilirubin>5	144	63.2	54.8 - 71.1
4 – Abbreviated Clinical AND ICD Criteria			
AST >50 & <400, ratio>1.5, bilirubin>3	70	**90.0**	80.5 - 95.9
AST >110 & <435, ratio>1.5, bilirubin>3	53	**94.3**	84.3 - 98.8
AST >110 & <435, ratio>2.0, bilirubin>3	48	**93.8**	82.8 - 98.7
AST >110 & <435, ratio>2.0, bilirubin>5	45	**95.6**	84.9 - 99.5

** Ratio refers to AST to ALT ratio*

Abbreviations: ICD = International Classification of Diseases, AST = aspartate aminotransferase, ALT = alanine aminotransferase; PPV = positive predictive value; CI = confidence interval

Abstract# 1091

Longitudinal Quality of Life Assessment in Liver Transplant - Feasibility Study and Early Results

O. M. Siddiqui, P. Polineni, A. J. Thuluvath, C. Loftus, *Northwestern University, Chicago, IL*

Purpose: In addition to survival, quality of life (QoL) is critical to optimizing care in liver transplantation (LT). Although QoL is associated with clinical outcomes in other settings, QoL assessments are not part of routine transplant care, and little is known about longitudinal changes pre- and post- LT. Furthermore, assessments performed by clinic staff can be time-consuming and cost prohibitive. Therefore, we aimed to measure QoL in pre- and post LT patients via brief monthly self-assessments.

Methods: A prospective single-center study included patients with cirrhosis evaluated for LT 1/2018 - 10/2020; both pre- and post- LT patients were included. Recruitment began in 10/2020 and is ongoing. The NIH Patient Reported Outcomes Measurement Information System (PROMIS) is used to measure QoL through online computerized adaptive tests (CATs) emailed to patients at baseline and repeated monthly. All PROMIS measures are reported as t scores referenced to the general US population with a mean of 50 and an SD +/- 10. A score above 50 indicates that a subject has a higher degree of the domain relative to the general US population.

Results: 39 patients were enrolled from 10/14 to 11/19 2020 [expected enrollment by 6/21 (ATC 2021) is 135]. 87% of patients completed all baseline surveys, 36% were female, 82% were White, 3% Black and 13% Hispanic. Etiology of cirrhosis was NASH (41%), ETOH (28%), HCV/HBV (18%), Biliary (13%), and Other (23%). 27 (69%) were pre-LT with a mean MELD 14.9 +/- 5.5 and 12 (31%) were post-LT with mean time since transplant of 1.9 months (range 0-5). The sample is not yet powered to show significance, but trends in the pre vs post LT comparison show an increase in perceived cognitive function (+6.3), and reduction of dyspnea (-5.6) and fatigue (-4.8), as well as increased spiritual health (+ 3). Pre/post LT physical function remains below the general population (42.7/40.8) while pain remains high (54.2/55.2) and social function drops (49.3/42.8). (Figure 1)

Conclusions: PROMIS CATs can successfully be used to measure QoL in pre- and post- LT patients via online self-assessments without assistance by a coordinator. Early results show high response rates (87%) and trends in changes pre- and post- LT, which are promising as enrollment continues. Change in QoL domain scores over time and association with adverse clinical outcomes will be examined as monthly data is collected. Thus, PROMIS CATs may provide a cost-effective way to longitudinally assess QoL in LT patients and optimize outcomes.

Abstract# 1092

Blood Pressure Variability Immediately After Liver Transplant Predicts the Likelihood of Long-Term Cardiovascular Events

K. N. Truitt[1], K. Chen[2], Y. Yano[3], D. Gregory[4], L. B. VanWagner[5], *[1]Northwestern Memorial Hospital, Chicago, IL, [2]Harvard University, Cambridge, MA, [3]Duke University School of Medicine, Durham, NC, [4]Northwestern University Feinberg School of Medicine, Chicago, IL, [5]Northwestern University Feinberg School of Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL*

Purpose: Cardiovascular disease is a leading cause of mortality in liver transplant recipients (LTRs). Adequate blood pressure (BP) control within one year after liver transplant (LT) is associated with improved survival and decreased cardiovascular events (CVEs). However, in clinical practice, extreme values of BP are often discarded, and the lowest or mean value is chosen as the "true" BP. In older adults and among perioperative cardiac surgery patients, this BP variability, independent of mean BP, is associated with adverse outcomes. Whether BP variability is associated with CVEs in LTRs is unknown.

Methods: We conducted a longitudinal cohort study of adult LTRs within a large tertiary care network in the United States between 2010-2016. Day-to-day BP variability within the first 60 days after LT was measured utilizing variability independent of the mean (VIM). To assess the association between early post-LT BP variability and future CVEs, we used Cox proportional hazard regression. Models were adjusted for mean BP, age, sex, race, time-varying BP medication use, and pre-transplant diabetes and atherosclerotic cardiovascular disease (ASCVD).

Results: Among 195 LTRs (32.3% female, 10.8% black, mean age 55.6 years), 19.0% had a CVE within a mean follow up of 3.01 years (standard deviation (SD) 2.08). The average range in systolic BP was 20.89 mmHg (SD 13.60) and diastolic BP was 12.65 mmHg (SD 6.55). Increased systolic BP variability was associated with a decreased risk of CVEs (Hazard Ratio (HR) 0.95, 95% confidence interval (CI) 0.92-0.99). This was particularly true for males (HR 0.95, CI 0.90-0.99) and patients with pre-LT ASCVD (HR 0.94, CI 0.88-0.98). There was a trend towards decreased mortality among male LTRs (HR 0.95, CI 0.09-1.01), but not females. Increased diastolic BP variability was also associated with a decreased risk of CVEs (HR 0.86, 0.78-0.95); specifically for persons younger than 65 (HR 0.87, CI 0.79-0.97), males (HR 0.85, CI 0.76-0.94), and persons without pre-LT diabetes (HR 0.90, CI 0.80-1.00) or ASCVD (HR 0.77, CI 0.65-0.91).

Conclusions: Increased BP variability, independent of mean BP, is associated with decreased CVEs in LTRs, while it is associated with adverse outcomes in other populations. We postulate that increased BP variability reflects a better vascular recovery in persons undergoing LT, but further research is needed.

Abstract# LB 83

Loneliness in Adults Awaiting Liver Transplantation at 7 U.S. Transplant Centers During the Covid-19 Pandemic

K. Berry[1], D. Kent[1], S. Seetharaman[1], R. Wong[1], Y. Mohamad[1], F. Yao[1], M. Duarte[2], B. Boyarsky[3], R. Rahimi[4], A. Duarte-Rojo[5], M. Kappus[6], M. Volk[7], D. Ladner[8], D. Segev[3], M. McAdams-DeMarco[3], E. Verna[9], D. Ganger[8], J. C. Lai[1], *[1]UCSF, San Francisco, CA, [2]Johns Hopkins, Baltimore, CA, [3]Johns Hopkins, Baltimore, MD, [4]Baylor, Dallas, TX, [5]Pittsburgh, Pittsburgh, PA, [6]Duke, Durham, NC, [7]Loma Linda, Loma Linda, CA, [8]Northwestern, Chicago, IL, [9]Columbia, New York, NY*

Purpose: Loneliness, defined by the National Academy of Medicine as "a subjective feeling of being isolated", has recently emerged as a strong predictor of adverse health effects and is of increasing concern given the COVID-19 pandemic. We aimed to characterize loneliness in patients with end-stage liver disease (ESLD) awaiting liver transplantation (LT).

Methods: We surveyed adult ambulatory cirrhosis patients awaiting LT at 7 U.S. sites during the COVID-19 pandemic (May2020-Jan2021) using the validated UCLA Three-Item Loneliness Scale by phone or video. Participants were asked to report if they felt: 1) they lack companionship, 2) left out, or 3) isolated using a 3-point scale (1=hardly ever, 2=some of the time, or 3=often). Participants were classified as "lonely" if they reported a score of ≥2 in at least 1 category. Frailty was assessed with the Liver Frailty Index (LFI); "frail"=LFI≥4.4. Logistic regression was used to associate loneliness and other factors.

Results: Of 454 participants, 36% were female, median age was 60 years (IQR 53-64), median MELDNa was 14 (IQR 10-19), and 14% were frail. 181 (40%) met criteria for "lonely" in at least 1 category; 49 (11%) met criteria for "lonely" in all 3 categories. Compared to those who were not lonely, those who reported feeling lonely were younger (58 v. 61y) and more likely to be female (46% v. 29%), frail (19 v. 11%), or have hepatic encephalopathy (62 v. 50%). There were no differences by race/ethnicity, disease etiology, ascites, or MELDNa score. In univariable analysis, age (OR 0.97, 95% CI 0.96-0.99), female sex (OR 2.16, 95% CI 1.46-3.21), frailty (OR 1.88, 95% CI 1.09-3.2), and hepatic encephalopathy (OR 1.60, 95% CI 1.09-2.35) were associated with loneliness. After multivariable adjustment, younger age (OR 0.97, 95% CI 0.95-0.99), female sex (OR 1.95, 95% 1.30-2.90), and frailty (OR 1.5, 95% CI 1.2-1.96), remained significantly associated with loneliness.

Conclusions: During the COVID-19 pandemic, loneliness was prevalent in patients with ESLD awaiting LT (40%). This is similar to rates reported in the general population (20-50%) during the pandemic, despite LT candidates being a select subgroup in which social support is a criterion for listing. In our cohort, younger age, female sex, and frailty were independently associated with loneliness. These data lay the foundation for future work investigating the extent to which loneliness impacts health outcomes in LT patients, as it does in the general population, and how targeting loneliness in interventions may facilitate improvements in frailty.

Liver: Immunosuppression and Rejection

Abstract# 1093

Changes in Liver Transplant Volume and Induction During the Covid-19 Era

T. Alhamad, J. Wellen, K. Lentine, M. Doyke, W. Chapman, Y. Al-Hosni, D. Axelrod, S. Chang, *Washington University School of Medicine in St. Louis, Saint Louis, MO*

Purpose: The rapid spread and high infectivity of COVID-19 resulted in disruption of transplant procedures at many centers, including pauses in living donor transplantation and limitation of life-saving transplants to candidates with highest need. We examined the contemporary trend of liver transplant, donor volume, and recipient induction regimens prior and during the pandemic.

Methods: Data on liver transplant procedures from the national organ registries, Organ Procurement and Transplantation Network, 1/1/2019-5/31/2020) and Scientific Registry of Transplant Recipients (6/1/2020-9/30/2020) were used. We excluded multiple organ transplantation.

Results: There were 6,316 liver transplant performed between Jan 2020 and Sep 2020, compared to 5,972 in the same period in 2019. The volume of deceased donor liver transplant plummeted in March, reached a nadir in April, and increased starting from May to return to the level similar to the same month in 2019. Similar trends

were seen for the liver organs that were recovered for transplant. For induction regimens, there was a decrease in the use of thymoglobulin and basiliximab, and an increase of no induction regimen, which usually involves intravenous steroids without antibody induction. Figure 1. Figure 2

Conclusions: While there is a decrease in the use of thymoglobulin and basiliximab, there is no evidence that avoiding induction agents will result in better outcomes if transplant recipients get exposed to SARS-CoV-2 shortly after transplant. More data is needed to examine the risk and severity of infection according to induction therapy.

Abstract# 1094

Evaluation of the Conversion from Tacrolimus to Sirolimus in Liver Transplant Recipients

H. Bakhtiari[1], S. Todd[2], H. Snyder[2], D. Lo[2], M. Flynn[2], *[1]Mercer University College of Pharmacy, Atlanta, GA, [2]Emory University Hospital, Atlanta, GA*

Purpose: The purpose of this study was to compare outcomes in liver transplant patients maintained on standard calcineurin inhibitor (CNI) therapy with tacrolimus versus those converted to a CNI-free regimen with sirolimus.

Methods: This single center, retrospective study evaluated outcomes in liver transplant patients from January 1, 2015 to June 10, 2020 at the Emory Transplant Center. Inclusion criteria for the study included liver transplant recipients who were 18 years or older and either maintained on tacrolimus or converted to sirolimus. The two-cohort design of this study included an intervention group composed of patients undergoing conversion therapy from tacrolimus to sirolimus and a control group consisting of matched patients maintained on tacrolimus therapy. The primary endpoint was estimated glomerular filtration rate (eGFR) at 6- and 12-months post-transplant.

Results: Of the 1452 patients that met inclusion criteria, 244 patients underwent conversion from tacrolimus to sirolimus. Tacrolimus patients were matched to sirolimus patients based on transplant indication, age, and renal function. As a result, the study included a total of 488 patients. Baseline characteristics were similar between groups. The mean age of patients was 61 years, and a majority of patients were Caucasian. The leading indications for transplant included hepatitis C, alcoholic cirrhosis, nonalcoholic steatohepatitis (NASH), and hepatocellular carcinoma. The mean eGFR at baseline was 67 mL/min/1.73m2 for the tacrolimus group and 60 mL/min/1.73m2 for the sirolimus group. At 6 months post-transplant, the mean eGFR for the tacrolimus group was 61 mL/min/1.73m2 compared to 54 mL/min/1.73m2 in the sirolimus group. Additionally, at 12 months post-transplant the mean eGFR for the tacrolimus group was 62 mL/min/1.73m2, while the mean eGFR for the sirolimus group was 57 mL/min/1.73m2. A greater decline in eGFR from baseline to 12 months was observed in patients maintained on tacrolimus at 5 mL/min/1.73m2 compared to patients switched to sirolimus at 3 mL/min/1.73m2. Biopsy proven acute rejection was observed more frequently in sirolimus patients at 15% compared to tacrolimus patients at 12%. The sirolimus group also experienced greater increases in total cholesterol, triglycerides, and blood pressure at 12 months.

Conclusions: Overall renal function as measured by eGFR was greater for patients maintained on standard CNI therapy post-transplant; however, a greater decline in eGFR from baseline to 12 months occurred in the tacrolimus group. Alternatively, graft rejection was observed more frequently in the sirolimus group when compared to tacrolimus. Previous studies among kidney transplant recipients have shown that conversion from tacrolimus to sirolimus resulted in renal recovery, however additional studies are needed to determine the potential benefits of this conversion therapy in liver transplant recipients.

Abstract# 1095

Early Reduction of Tacrolimus Trough Levels Improves Long-term Kidney Function without Increase in Incidence of Acr

M. Chen[1], B. Loza[1], A. Chang[1], R. Byfield[2], K. Olthoff[1], A. Shaked[1], *[1]Department of Surgery, University of Pennsylvania, Philadelphia, PA, [2]Data Analytics Center, Penn Medicine Information Systems, University of Pennsylvania Health System, Philadelphia, PA*

Purpose: We examined the impact of clinical practice management of tacrolimus trough levels in liver transplant recipients on kidney function and incidence of rejection in the first 5 years after transplantation.

Methods: Serial tacrolimus trough levels, eGFR, and the incidence of acute rejection were collected on adult liver transplant recipients at 6 months and yearly up to 5 years after transplantation (n=874). Change in tacrolimus levels at each time point was correlated with change in eGFR, and with incidence of rejection.Participants were divided into tertiles based on magnitude of adjustment in tacrolimus trough dosing from baseline (defined as 3 months after surgery) with levels at 6 months and yearly from one to five years. Primary endpoint was change in eGFR at 6 months and subsequently at 1 year intervals compared to baseline post-transplant eGFR. Secondary endpoint was rejection episodes at various time intervals. Patients age at transplant, sex, year of transplant, pre-transplant eGFR, tacrolimus trough levels at baseline, and dialysis status were included as covariates in the regression analysis.

Results: Participants with the greatest reduction in tacrolimus trough dosing (first tertile) showed improvement in eGFR compared to the patients with the least reduction in tacrolimus doing (the third or reference tertile) across all time points. This was most apparent at 6 months and 1 year after transplantation (increase in eGFR by 8.79±1.37 mL/min and 7.83±1.66 mL/min, respectively), and remained consistent over the study time period. There was a statistically significant increase in percentage of participants requiring dialysis at 4 and 5 years in the reference group (with least tacrolimus adjustment) (6.9% and 10.3%, respectively). There was no difference in the incidence of rejection across tertiles at one year (2.0% vs. 2.0% vs. 3.5%, p = 0.43).

Conclusions: Early and sustained reduction in tacrolimus levels after transplantation were associated with long term improvement in kidney function, with no increase incidence of rejection. Minimal changes levels led to higher incidence of end-stage kidney failure.

Abstract# 1096

Dynamics of IgG Subclass as a Mechanism of Desensitization Using Rituximab for Presensitized Patients Undergoing Living Related Liver Transplantation

H. Egawa[1], K. Ide[2], T. Ishizuka[3], H. Ohdan[4], Y. Kotera[1], T. Kato[1], A. Ohmori[1], Y. Hirata[1], G. Shibuya[1], S. Yamashita[1], S. Ariizumi[1], *[1]Tokyo Women's Medical University, Tokyo, Japan, [2]Surgery, Hiroshima University, Hiroshima, Japan, [3]Clinical Laboratory, Tokyo Women's Medical University, Tokyo, Japan, [4]Hiroshima University, Hiroshima, Japan*

Purpose: Although impact of preformed HLA-related donor specific antibody (DSA) and necessity of desensitization in liver transplantation (LT) has been recognized, mechanisms of desensitization in LT is not clarified yet.Aim: To examine mechanisms of desensitization for preformed DSA in living related liver transplantation (LDLT).
Methods: Patients and Method: Six patients whose MFI of LABScreen single test of class 1 or class 2 DSA was greater than 10,000 underwent desensitization treatment using rituximab with a dose of 375 mg/m^2 2 weeks before LDLT, whether cytotoxic direct crossmatch (CDC) is positive (n=3) or negative (n=3). As immunological assessments, CDC (T cell, B cell worm and B cell cold), flow crossmatch test (FCXM), flow PRA test, LABScreen single test for patients with positive PRA, and LABScreen complement test (C1q test) for positive CDC samples were examined. Further, IgG subclass analysis was added to 3 patients (#1, #2, #3) whose CDC turned to negative. The minimum follow-up period was 560 days after LT.
Results: Results: The value of T cell/B cell CDC was 100%/100% in #1 and #3, and 0%/100% of #2. In #1, T cell CDC turned 0% after POD 3. B cell CDC (warm/cold) was remained 100%/100% until POD 64, 30%/0% on POD114 and 0%/0% on POD 900. FCXM-IgG turned to negative on POD114 but remained positive on POD900. Single bead MFI of DSA (A33, B44, B51, DR13, DR14) was over 10,000 before LT and decreased with fluctuation after LT and 0, 3,916, 8,457, 2,932, and 2,847 on POD 900, respectively. MFI of C1q test turned to 0 on POD 3. IgG subclass analysis showed persistent domination of IgG1 in A33, B44, B51 DSAs and switching from IgG1 dominant to IgG2 dominant after LT in DR13 and DR14 DSAs. On the other hand, values of CDC, FCXM-IgG, single bead MFI and C1q test changed harmonically and IgG subclass was IgG1 dominant in #2 and #3.
Conclusions: Discussion: In #1, Subclass switch from IgG1 from IgG2 could contribute to diminishing of complement activation of Class 2 DSA, while decrease of total amount of antibody with dominance of IgG1 could contribute in class 1 DSA of #1 and class 1 and 2 in #2 and #3.Conclusion: Subclass dynamism could be a possible mechanism of desensitization.

Abstract# 1097

Quantifying the Interaction Between Posaconazole and Tacrolimus in Liver Transplant Recipients: A Practical Approach

B. Lane[1], U. Kaszubski[1], A. Freeman[1], B. Wise[1], L. Hutchinson[1], M. Janusek[1], G. Therapondos[2], H. Bohorquez[3], S. Anders[1], *[1]Pharmacy, Ochsner Medical Center, New Orleans, LA, [2]Hepatology, Ochsner Medical Center, New Orleans, LA, [3]Transplant Surgery, Ochsner Medical Center, New Orleans, LA*

Purpose: The interaction between tacrolimus (FK) and posaconazole (POSA) is well documented, however the extent of this interaction and the practical management has yet to be fully described post-liver transplant. Literature evaluating this interaction has been hindered by small sample sizes, limited patient populations, use of various POSA formulations and little evidence describing the timing of the interaction. Recent construction at this institution prompted the use of POSA due to its coverage of mold species. The goal of this study is to quantify the interaction between FK and delayed release POSA tablets.
Methods: This was a single-center, retrospective study that included adult liver transplant recipients between 8/1/17 - 9/1/20. The primary endpoint was the difference in the day 5 FK C/D in the POSA group compared to a control. Secondary endpoints included the incidence of acute kidney injury (AKI), biopsy proven acute rejection (BPAR) within one month of azole discontinuation, length of stay, frequency of a patient having one or more supra- or subtherapeutic FK trough, and therapeutic troughs by day 2 & 5.
Results: A total of 217 patients were included. Baseline demographics were similar between groups. Day 5 FK C/D with POSA was approximately three-fold that of the control group. The effects of this interaction impacted the day 2 FK C/D but had a more pronounced effect on the day 5 FK C/D. The POSA group was more likely to have a therapeutic trough (5-15 ng/mL) by day 2 & 5 and at time of hospital discharge. This group was also more likely to have a supratherapeutic trough, however this did not result in a higher incidence of AKI. Upon discontinuation of POSA, this group was highly likely to experience a subtherapeutic level, however this did not lead to more BPAR.
Conclusions: This study is the first to evaluate this interaction in post-liver transplant recipients utilizing delayed release POSA tablets in combination with FK. Concomitant therapy resulted in a three-fold increase in FK C/D compared to a control, supporting the empiric dose reduction per the package insert to maintain similar FK trough concentrations. Impacts of this interaction were observed as early as day 2 however the effects continued upwards of day 5, requiring a significantly lower weight-based FK dose.

Table 1. Baseline demographics

Characteristic	POSA (n=41)	Control (n=176)	p-value
Age (years), mean (±SD)	55.1 (12.54)	56.6 (10.61)	0.49
Sex (male), n (%)	29 (71)	130 (74)	0.68
Weight (kg), mean (±SD)	89.5 (22.7)	87.4 (20.2)	0.51

Abstract# 1098

Highly Sensitized Simultaneous Liver-kidney Transplant Recipients Show a Reduction in Panel Reactive Antibodies and No Kidney Rejection 1-year Post-transplant

M. Moaddab, J. V. Nolte Fong, C. M. Mobley, A. Saharia, M. J. Hobeika, R. McMillan, S. G. Yi, R. J. Knight, A. Gaber, R. Ghobrial, *Houston Methodist Hospital, Houston, TX*

Purpose: The liver is unique in that it is considered an immunologically tolerant organ against graft destruction by antibodies. Simultaneous liver-kidney transplantation (SLKT) are often performed under the assumption that the liver confers an immunologic protection to a kidney allograft. This study evaluated outcomes on pre-SLKT allosensitization in highly sensitized recipients.

Methods: This single-center, retrospective study assessed SLKT recipients between January 2016 - June 2019. We defined high sensitization as panel reactive antibody (PRA) levels greater than 50%. Pre-existing and *de novo* donor specific antibodies (DSA) were trended 15 months post-transplant. Rejection rates, serum creatinine and patient survival within the first year post-transplant were assessed. Human leukocyte antigen testing was performed via single antigen beads with a 2,000 mean fluorescence intensity (MFI) cut-off for positivity. No desensitizing strategies occurred pre- or post-SLKT.

Results: Ten SLKT patients were highly sensitized and included in the analysis. A 71% class I and 56% class II average reduction in PRA was observed from baseline to 1-year post-transplant. Four patients had pre-existing DSAs, all of which cleared by three months post-SLKT. Five patients had *de novo* DSA formation, three of which had clearance and two with persistent DSAs. No biopsy-proven kidney rejections and 2 (20%) acute cellular liver rejections occurred. Graft and patient survival was 100% 1-year post-SLK.

Conclusions: SLKT in highly sensitized recipients does not result in post-transplant kidney rejection at 1 year. Despite rejection in 20% of the liver allografts, no grafts were lost. A liver allograft may confer a protective benefit to a kidney allograft in sensitized SLKT recipients.

Figure 1. Class I and Class II post-SLKT

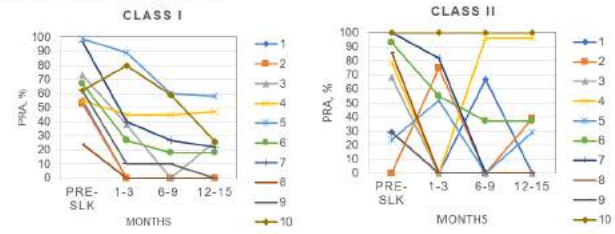

Table 1. One-Year Rejection, Serum Creatinine and Patient Survival in SLKT Recipients

Patient	Kidney Rejection	Liver Rejection	Serum Creatinine, mg/dL	Patient and Graft Survival
1	None	None	1.29	Yes
2	None	None	1.1	Yes
3	None	Acute cellular	0.9	Yes
4	None	None	1.2	Yes
5	None	None	1	Yes
6	None	Acute cellular	1.4	Yes
7	None	None	0.8	Yes
8	None	None	1.2	Yes

Abstract# 1099

Varicella Hepatitis Mimicking Immune Checkpoint Inhibitor-induced Liver Toxicity

M. J. Weiss[1], X. Zhang[2], E. K. Spengler[1], *[1]Gastroenterology and Hepatology, University of Wisconsin, Madison, WI, [2]Pathology, University of Wisconsin, Madison, WI*

Purpose: Nivolumab is an anti-PD-1 monoclonal antibody belonging to a class of immune checkpoint inhibitors (ICI) used for many malignancies. A major limitation to their use is immune-related adverse events (irAEs) that lead to organ-specific inflammation that can be fatal if not promptly recognized and treated with aggressive immunosuppression. Immune-mediated acute liver injury (ALI) is a well described irAE and is often treated empirically. We describe a case highlighting the importance of early liver biopsy in patients not responding to treatment for immune checkpoint inhibitor-induced liver injury.

Methods: N/A

Results: A 70 year-old man with stage IIA esophageal squamous cell carcinoma status-post neoadjuvant chemo/radiation therapy and esophagectomy was treated with nivolumab. One month post-treatment he was admitted with likely nivolumab-induced myocarditis and was treated with methylprednisolone 1 mg/kg IV daily and one dose of infliximab. At discharge he was placed on an oral steroid taper. He had no liver injury during this stay.

He returned within a week with abdominal pain and ALI with AST 2020 U/L, ALT 1750 U/L, bilirubin 3.2 mg/dL, alkaline phosphatase 211 U/L, INR 1.3. CT was unrevealing. He was treated with methylprednisolone and infliximab for suspected ICI-induced irAE. Thrombosis, autoimmune hepatitis, CMV and EBV were excluded. ALI worsened and hepatology was consulted (AST 3970 U/L, ALT 2883 U/L, alkaline phosphatase 203 I/L, bilirubin 5.4 mg/dL, INR 1.9). A liver biopsy was recommended, but he suffered cardiac arrest and expired the following day. Autopsy revealed disseminated varicella zoster virus (VZV) infection involving the liver (Fig. 1), lung, heart, bowel, esophagus and kidney.

Conclusions: Recognition of immune-mediated liver injury has increased with the growing use of ICI, leading to protocoled immunosuppression regimens designed to empirically treat these often severe liver injuries. Unfortunately, these protocols are often initiated by oncology without hepatology involvement. Although this has simplified treatment and decreased the need for biopsy, it has removed hepatology from the care of patients with ALI. As this case highlights, patients receiving ICI are at risk of other forms of ALI, including drug-induced liver injury, cancer infiltration, infections and thrombosis. Hepatologists should advocate for complete evaluation of all patients with ALI. Biopsy should be considered early if they do not improve as expected.

Liver: Recipient Selection

Abstract# 1100

Early Portal Vein Ligation in the Setting of Shorter Hepatectomy May Contribute to Better Surgical Outcomes in Deceased Donor Liver Transplantation

K. Delvecchio, T. Kitajima, A. Mohamed, S. Yeddula, M. Tayseer, T. Ivanics, K. Collins, M. Rizzari, A. Yoshida, M. Abouljoud, S. Nagai, *Henry Ford Hosptial, Detroit, MI*

Purpose: Few published reports have suggested lower blood loss in association with early portal vein ligation (e-PVL) during liver transplantation surgery, however there are currently no studies describing the outcomes with respect to hepatectomy duration or the relationship of e-PVL to recipient hepatectomy time (ePVL/H ratio). The aim of this study is to evaluate possible effects of shortened hepatectomy in conjunction with e-PVL on surgical and post-transplant outcomes.

Methods: We evaluated adult deceased donor liver transplants between 2013-2018. Patients undergoing re-transplant, multiorgan or living donor liver transplantation

were excluded. Possible effects of hepatectomy and additionally e-PVL on surgical and post-transplant outcomes were assessed. Patients were categorized into 2 groups: shorter (<90 minutes) and longer hepatectomy groups (≥90 minutes).

Results: A total of 451 patients were eligible. Median PVL and hepatectomy time were 90 and 129 minutes, respectively. Of these 451 patients, 57 and 384 were categorized into the shorter and longer hepatectomy groups. Recipient characteristics, including MELD score, were similar between two groups. Shorter-hepatectomy group had significantly shorter PVL time (47 vs 97 minutes, P<0.001) and lower e-PVL/H ratio (0.60 vs 0.72, P<0.001). The shorter hepatectomy group had lower amount of RBC (2 vs 4 units, P=0.014) and FFP (4 vs 6 units, P=0.007) transfusion and shorter cold ischemia time (4.8 vs 5.1 hours, P=0.049). One-year patient survival was comparable (97.9% vs. 91.8%, P=0.100). Longer hepatectomy time, but not PVL, was associated with an increased risk of one-year post-transplant mortality (HR 1.01 [per minute], p=0.021).

Conclusions: In the setting of shortened recipient hepatectomy, early portal vein ligation with respect to hepatectomy duration may contribute to improved surgical outcomes.

Abstract# 1101

Liver Transplantation in Septuagenarians

L. Egbert[1], D. Das[1], S. Ohara[2], J. Wagler[3], G. Mahdi[4], B. Aqel[5], A. Moss[5], K. S. Reddy[5], C. Jadlowiec[5], *[1]Mayo Clinic Alix School of Medicine, Scottsdale, AZ, [2]Valleywise Health General Surgery Residency Program, Phoenix, AZ, [3]HonorHealth John C. Lincoln, Phoenix, AZ, [4]Mayo Clinic Alix School of Medicine, Phoenix, AZ, [5]Mayo Clinic, Phoenix, AZ*

Purpose: The average age of liver transplant (LT) recipients has continued to increase. In spite of this, with the ongoing organ shortage, liver transplantation in the elderly remains controversial. Our goal was to assess the outcomes of LT recipients who were 70 years or older.

Methods: We assessed LT recipients 70 years of age or older who received a LT at our center between January 2015 and June 2020.

Results: During this period, 144 patient ≥70 years were evaluated for LT at our center; 54.2% were denied candidacy, 35.4% were approved and transplanted, 5.6% were approved but then delisted, and 4.9% remain active awaiting LT. Of the 697 LT performed at our center during this time, 45 (6.5%) were in recipients who were 70 years or older. Of these 45 recipients studied, 7 underwent a simultaneous liver-kidney transplant. Four recipients (8.9%) were re-transplants. The most common indications for LT were nonalcoholic steatohepatitis (NASH) (28.9%) and alcohol-related liver disease (20.0%); 26.7% had hepatocellular carcinoma (HCC). The average Model for End Stage Liver Disease (MELD) score was 21.2±8.0. Comorbidities studied included diabetes (28.9%), hypertension (26.7%), and coronary artery disease (11.1%). Assessments of functional ability prior to LT included 6-minute walk test (341.6±96.3 meters) and Karnofsky score (median 80.0). Donation after cardiac death (DCD) donors were utilized in 33.3% of transplants. Median intensive care unit (ICU) length of stay (LOS) was 1 day; hospital LOS was 6 days. The majority of LT recipients were discharged home (n=37, 82.2%) with 13.3% requiring acute rehabilitation and 2.2% requiring a skilled nursing facility. One-year patient survival was 97.8% and one-year graft survival was 93.3%.

Conclusions: There has been an increase in the number of patients ≥70 years referred for LT. With appropriate pre-transplant assessment, septuagenarians undergoing LT can have favorable outcomes. Age itself should not be an absolute contraindication for pursuing liver transplantation.

Recipient Demographics	
	Septuagenarian LT Recipients (n=45)
Age (median)	71.3±1.4 (71.0)
Female	12 (26.7%)
MELD (median)	21.2±8.0 (22.0)
SLK recipients	7 (15.6%)
Re-LT recipients	4 (8.9%)
6 minute walk (meters)	341.6±96.3
Karnofsky score (median)	80.0

Abstract# 1102

Implementation of a High-risk Medication Report for Waitlisted Liver Transplant Candidates

M. M. Eiting[1], H. Yeh[2], M. Cote[1], S. Shao[1], A. B. Scherrer[2], L. Dageforde[2], N. Elias[2], C. Rogers Marks[1], *[1]Pharmacy, Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, MA*

Purpose: Use of high-risk medications (HRMs) at the time of liver transplant may lead to delays in surgery or peri-operative complications (bleeding, drug-drug interactions (DDI), impaired healing, lapse in therapy). Additionally, patient-specific serologies may require time-sensitive pharmacological intervention to prevent recurrent disease. HRMs identified include direct-oral anticoagulants (DOAC), dual antiplatelet therapy (DAPT), mammalian target of rapamycin inhibitors (mTORi), buprenorphine-containing therapies, and methadone. The goal of this QI project is to describe the initial development and implementation of electronic medical record (EMR) generated reports that identify HRMs, allergies and serologies in waitlisted liver transplant candidates (LTCs) in real-time.

Methods: This prospective, quality improvement project was implemented in August 2020 at a 1000-bed academic medical center. Reports identified HRMs, allergies and serologies in real time for LTCs via EMR) data-extraction reports with supplemental chart review. Reports were compiled into a spreadsheet with interprofessional notification to ensure appropriate intervention prior to transplantation. Time to intervention and action taken are reported using descriptive statistics.

Results: A total of 62 LTCs were identified to be high risk secondary to HRM, allergy or positive HBsAg serology between September to December 2020. Interventions were recorded as seen in Table 1. Time to intervention deemed as addition of alert in EMR or medication issue resolved. The most common medication-related interventions included medication discontinued (11), note added to patient chart (9), changing to preferred therapy (3), and updating medication list with discontinuation (1).

Conclusions: Solid organ transplant candidates have multiple providers and variable wait times prior to transplantation, where real-time EMR reviews of LTCs may help facilitate time-appropriate intervention prior to transplantation. Future efforts include expanding EMR review to all solid organ transplant waitlist candidates, with information extraction to be adjusted for relevance per organ.

Abstract# 1103

Can an Organ Survive for More Than 100 Years Between Donor and Recipient

R. Gruessner, J. Renz, A. C. Gruessner, *SUNY Downstate Medical Center, Brooklyn, NY*

Purpose: It has been hypothesized that parenchymal grafts have a longer life expectancy than the cardio-cerebro-vascular system. We investigated the occurrence of deceased-donor liver (DDOLT), deceased-donor renal (DDRT), and living-donor renal allografts (LDRT) that have achieved or come close to 100 years of physiologic function in the donor and recipient.

Methods: All adult single-organ transplants from donors > 70 years of age, DDOLT (n=5,427), DDRT (n=2605), and LDRT (n=616) reported to UNOS/OPTN from 10/87 to 03/20 were evaluated. LDOLT were not considered due to the relative novelty of this procedure. Allograft survival was calculated according to the equation: Overall Survival = Allograft Age at Donation + Allograft Survival; it was categorized as age of 90-<95 years, 95-<100 years, or >=100 years and longer. Graft survival was defined as function time to date, most recent follow-up or death, re-listing for transplant, or (for kidney transplants) initiation of renal replacement therapy. Multivariate analysis assessed predictors of physiologic allograft survival in liver and kidney transplants.

Results: Table 1 shows the characteristics and outcomes. Outcome of DDOLT increased over time in general and 336 grafts showed physiological function > 90 years; in 14 cases the duration of function was > 100 years. The longest function time is 106.3 years and counting. Likewise, DDRT and LDRT allograft survival

improved throughout the study period: 33 DDRT and 12 LDRT were still functioning at 90 years. In contrast to DDOLT, only 2 LDRT graft reached the 100 year mark. Multivariate analysis of each cohort verified that good donor and recipient management factors are potential predictors of allograft longevity.$$Table1

Conclusions: Organ longevity in 2 different individuals exceeding 100 physiologic years is possible. It represents a small but increasing minority of grafts in transplant recipients. It is expected that more grafts will reach this mark with increasing follow-up time. The observation of extended longevity is higher among liver vs. kidney allograft recipients. Increases in allograft longevity between DDRT and LDRT are similar over time but more common in LDRT.

	DD OLT	DD RT	LD RT

Abstract# 1104

Regional Trends in Liver Transplantation for Nonalcoholic Steatohepatitis

C. L. Hanlon[1], B. Saberi[2], L. Yuan[1], *[1]Internal Medicine, University of Southern California, Los Angeles, CA, [2]Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Boston, MA*

Purpose: This study aims to evaluate regional trends in liver transplantation (LT) among adults in the United States (US) with nonalcoholic steatohepatitis (NASH), with particular emphasis on changing trends before and after introduction of direct-acting antiviral agents for hepatitis C (HCV).

Methods: Using data from the United Network for Organ Sharing (UNOS) LT database, we evaluated diseased donor liver transplants and waitlist registration for patients listed for transplant with NASH cirrhosis in the US between January 1, 2004, and December 31, 2019. Main outcomes included national and regional trends in liver transplant and waitlist registration for NASH. Regional data was stratified as established by the Organ Procurement and Transplantation Network (OPTN).

Results: Between 2004-2019, the annual total number of LT for NASH increased consistently. A total of 11,198 transplants were performed on patients listed for NASH during the study period, the majority (57.0%) of which were transplanted in the post-HCV treatment era between 2014 and 2019. OPTN Region 3 performed the most total LT for NASH over the study period (n=2314), while Region 6 performed the least total LT for NASH (n=218). Every OPTN region showed an increase in total number of LT performed over the study period, with the majority of regions growing most precipitously between 2014-2019. In the post-HCV era, annual LT for NASH grew the most in OPTN Region 5 (207.5%), followed by Region 1 (193.8%) and Region 4 (183.3). Regions 2 (136.5%), 8 (124.5%), 7 (120.4%), and 9 (111.1%) showed relatively moderate growth in total LT between 2014-2019, while Regions 10 (96.8%), 6 (89.5%), 3 (87.4%), and 11 (76.1%) showed mild growth in LT for NASH.

Conclusions: Total LT for patients with NASH has dramatically increased in the US particularly since 2014, suggesting changing trends of transplantation allocation in the post-HCV era. Heterogeneity of regional growth rate in LT for NASH may be accounted by the regional variation in prevalence of NASH and regional LT policies for NASH. The consistent growth of LT for NASH across all OPTN regions demonstrates a paradigm shift of future liver transplantation.

Abstract# 1105

Implementation of an Alcohol Screening Program Identifies Active Pre-transplant Drinking and Allows Engagement in Chemical Dependency Treatment

N. Lim[1], T. Leventhal[1], M. Thomson[1], M. Hassan[1], J. Thompson[1], S. Chinnakotla[2], V. Kirchner[2], T. Pruett[2], R. Kandaswamy[2], V. Humphreville[2], A. Adams[2], J. Lake[1], *[1]Division of Gastroenterology, Hepatology and Nutrition, University of Minnesota, Minneapolis, MN, [2]Division of Transplantation, University of Minnesota, Minneapolis, MN*

Purpose: Alcohol (ETOH) is an important cause of cirrhosis in the US today. Screening patients for ETOH use prior to LT is important to identify and treat ETOH misuse. We report the findings from the implementation of a ETOH screening program for pre-LT patients at our center.

Methods: As part of a QI initiative starting on 6/1/2016, all patients undergoing LT evaluation had one-time testing for ETOH use, while patients undergoing LT evaluation for ALD underwent mandatory quarterly screening for ETOH use, with urine ethyl glucuronide (EtG). Any LT evaluation patient underwent EtG testing whenever ETOH misuse was suspected. Adherence to screening was defined as completion of one-time EtG testing in all LT evaluation patients and completion of quarterly EtG tests until LT or waitlist removal. A positive test was defined as urine EtG>500ng/ml, indicative of significant ETOH use. In the event of a positive test, the LT evaluation was placed on hold and a protocol was initiated. Upon satisfactory completion of the protocol, LT evaluation was resumed or the patient was re-activated on the LT waiting list.

Results: 868 patients started a LT evaluation from 6/1/2016 to 9/30/2020. Median age at LT evaluation was 58, 538 (62%) patients were male, 281 (33%) patients had ALD and 670 (78%) patients were white. 177 patients were listed for ALD- median age 56, 126 (71%) male and 147 (83%) white. Adherence rates to one-time screening for all LT evaluation patients and routine EtG testing in patients listed for ALD were high but decreased in 2020 (Table 1). Reasons for non-adherence included inpatient LT evaluation, hemodialysis & patient refusal. 31 patients were EtG(+) over the study period- 4 patients with NASH, 4 patients with HCV and 1 patient

with AIH. In patients listed for ALD, 8/177 (4.5%) patients had a positive EtG test. 8/31 (25.8%) patients completed chemical dependency treatment after EtG(+) and 3/31 (9.67%) patients later underwent LT.

Conclusions: ETOH screening is feasible and successfully identifies patients actively engaging in ETOH consumption, even in patients with no formal diagnosis of ALD. Implementing systematic ETOH screening in pre-LT patients identifies patients at highest risk for post-LT relapse and provides a comprehensive framework for additional chemical dependency resources to allow the best chance of post-LT success.

Table 1- Adherence to ETOH Screening

Year	All LT Evaluation	Listed ETOH
2016	73/97 (75%)	25/28 (89%)
2017	133/171 ((78%)	25/26 (96%)
2018	164/210 (78%)	46/48 (96%)
2019	183/223 (82%)	50/55 (91%)
2020	105/167 (63%)	15/20 (75%)
p-value (trend)	0.0003	0.09

Abstract# 1106

Serum Phosphatidylethanol is Superior to Urine Ethyl Glucuronide for Detection of Alcohol Use in Pre-transplant Patients

N. Lim[1], T. Leventhal[1], M. Thomson[1], M. Hassan[1], J. Thompson[1], S. Chinnakotla[2], V. Kirchner[2], T. Pruett[2], R. Kandaswamy[2], V. Humphreville[2], A. Adams[2], J. Lake[1], *[1]Division of Gastroenterology, Hepatology and Nutrition, University of Minnesota, Minneapolis, MN, [2]Division of Transplantation, University of Minnesota, Minneapolis, MN*

Purpose: More patients are presenting for liver transplant (LT) evaluation for alcohol-related liver disease (ALD). Detection of ETOH use has significant implications for patients undergoing LT evaluation. Urine ethyl glucuronide (EtG) and serum phosphatidylethanol (PEth) are the two most common biomarkers validated in patients with cirrhosis. We compared rates of screening for ETOH use using EtG and PEth in pre-LT patients over a 12-month period.

Methods: As part of a QI initiative starting on 6/1/2016, all patients undergoing LT evaluation had one-time testing for ETOH use, while patients undergoing LT evaluation for ALD underwent mandatory quarterly screening for ETOH use with EtG. All patients got EtG testing if ETOH misuse was suspected. From 10/1/2019 to 9/30/2020, we incorporated quarterly PEth testing into our protocol. Adherence to screening was defined as completion of quarterly testing for ETOH use until LT or waitlist removal. EtG(+) was defined as EtG>500ng/ml whereas PEth(+) was defined as PEth>20ng/ml, both levels indicative of significant ETOH use. In the event of a positive test, the LT evaluation was placed on hold and a protocol was initiated. Upon satisfactory completion of the protocol, LT evaluation was resumed or the patient re-activated on the LT waiting list.

Results: 226 patients started LT evaluation for any cause of liver disease over the study period while 31 patients with ALD were ultimately listed for LT. Median patient age at LT evaluation was 57, 132 (58%) patients were male and 186 (83%) patients were white. In patients listed for ALD, median age was 46, 19 (61%) patients were male and 27 (87%) patients were white. 146 (65%) patients undergoing LT evaluation had one-time ETG testing whereas 191 (85%) patients had PEth testing, p<0.0001. 24 (77%) patients listed for ALD were adherent to ETOH screening using EtG compared to 31 (100%) patients for PEth, p<0.0001. There were 7 patients who were EtG(+) over the study period compared to 16 who were PEth(+) for all patients undergoing LT evaluation, p= 0.057. 3 patients were both EtG & PEth(+). In the ALD patients, 0 were EtG(+) compared to 4 PEth(+) in 3 patients (2 patients with ETOH hepatitis). 6/23 (26%) patients with positive ETOH tests started chemical dependency treatment while 1/23 (4.3%) patient later underwent LT. An additional 10 patients who started LT evaluation before the study period were PEth(+).

Conclusions: Ease of testing makes PEth superior to EtG for both initial and routine screening for ETOH use in patients undergoing evaluation or listed for ALD. PEth is also superior for detection of ETOH misuse in these patients. For these reasons, our center has retired EtG for PEth to screen for ETOH use in patients undergoing LT evaluation.

Abstract# 1107

A Shift in Paradigm: Phosphatidylethanol Testing to Monitor for and Address Alcohol Recidivism Following Liver Transplantation

F. M. Nimri[1], S. Naffouj[1], F. Askar[1], A. Singh[2], H. Gonzalez[2], S. Jafri[2], *[1]Internal Medicine, Henry Ford Hospital, Detroit, MI, [2]Gastroenterology, Henry Ford Hospital, Detroit, MI*

Purpose: Phosphatidylethanol (PEth) is a phospholipid that forms in the presence of ethanol with a long half-life compared to other alcohol detection tests. PEth testing is highly sensitive and specific and has become an important factor in the process of pre-transplant evaluation as well as post-transplant follow-up. We evaluated the role of PEth in identifying recidivism and the impact of psychological intervention in identified patients.

Methods: We performed a retrospective study at a large tertiary care center of all patients who had alcohol recidivism after liver transplant demonstrated by a positive PEth test between 1/2018 and 1/2020. PEth test was considered positive if level was > 20 ng/dl. Intervention by psychologic counseling and relapse prevention was offered and patients were followed to assess if they were able to abstain from alcohol following intervention.

Results: A total of 20 patients (mean age 53.35 ± 8.97 years) were identified. All patients were white, and 14 (70%) were males. 17 patients (85%) had prior known alcoholic liver disease, 1 had nonalcoholic steatohepatitis (NASH), and 2 patients had cryptogenic liver disease. 19 patients had liver cirrhosis prior to transplant, and one had acute alcoholic hepatitis. 4 of the patients had pre-transplant PEth test and they were all negative. Mean PEth level post-transplant was 406 ng/ml. 11 patients agreed to undergo a psychological intervention to aid in alcohol cessation including relapse prevention (7/11), Alcoholic Anonymous (AA, 2/11), inpatient rehab + AA sessions (1/11), and relapse prevention + AA (1/11). 8 out of the 11 patients undergoing intervention reported abstinence on subsequent visits, however a follow-up PEth test was positive in 2 patients out of those 8 patients. 9 patients did not receive any intervention and continued to drink. 3 out of 9 had PEth test and it was positive (mean PEth level 297 ng/ml). 5 out 20 patients had graft rejection and only 1 of those 5 underwent a psychosocial intervention and stopped drinking. 2 patients died; both continued to drink post-transplant. One died of acute alcoholic hepatitis and was from the no intervention group, while the other underwent an intervention but nonetheless continued to drink and died due to a falling accident.

Conclusions: PEth test has been largely implemented in the process of liver transplant evaluation and post-transplant follow-up to ensure abstinence and compliance with the transplant requirements. It has recently played a role in pre-transplant evaluation. In this study, we found that PEth testing identified patients who had recidivism and those who continued to use alcohol despite undergoing relapse prevention. Larger studies are needed to accurately evaluate the benefit of broader PEth testing in post-liver transplant follow-up.

Abstract# 1108

Recent Trends and Outcomes of Liver Transplantation for Non-alcoholic Steatohepatitis versus Alcohol Liver Disease in the United States: Obesity Might be Protective

K. Okumura, I. Lee, H. Sogawa, G. Veillette, D. John, T. Diflo, R. Bodin, D. Wolf, S. Nishida, *Surgery, Westchester Medical Center/New York Medical College, Valhalla, NY*

Purpose: Nonalcoholic steatohepatitis (NASH) and alcohol liver disease (ALD) are rapidly growing indications for liver transplantation (LT). The recent trends and outcomes in NASH and ALD are limited.

Methods: We analyzed data from the United Network for Organ Sharing (UNOS) between 2002 and 2016. We excluded hepatitis C virus co-infection and compared the trends and outcomes in NASH and ALD.

Results: 19,581 LTs were performed during the study period, of which 8,289 LTs were for NASH and 11,292 LTs were for ALD. Compared to ALD, NASH group had older median recipient age (60 vs 55, p<0.01), female dominance (44 vs 22%, p<0.01), high percentage of Caucasian (81 vs 78%, p<0.01) and higher median BMI (32 vs 28, p<0.01). In NASH, Pre-LT diabetes rate was significantly higher, but ventilation rate and dialysis rate were significantly lower (66 vs 21%; 3.5 vs 5.1%; 16 vs 17%; p<0.01, respectively). Compared to ALD, the outcomes of NASH were inferior in five-year graft survival and five-year overall survival (77 vs 78%,

p=0,03; 80 vs 81%, p<0.01). In cox regression multivariable analysis for five-year graft survival, higher recipient age, male, Caucasian, pre-LT diabetes, pre-LT dialysis, ventilation on LT, Transjugular intrahepatic portosystemic shunt (TIPS), portal vein thrombosis (PVT), higher MELD score, African American or Hispanic donor and higher donor risk index (DRI) were significantly associated with negative outcomes. Hispanic or Asian recipient, higher recipient BMI and recent transplant year had significantly protective effects. The etiology of NASH vs ALD did not show significant difference in multivariable analysis (p=NS).

Conclusions: NASH and ALD had comparable post-transplant outcomes in graft survival and overall survival. Pre-transplant diabetes, dialysis, ventilation status, TIPS, PVT and DRI were associated with poor outcomes. We also showed the improvement of LT in recent years and protective effects of recipient BMI.

Table 1 Baseline characteristics of the study population

Abstract# 1109

Variation of Liver and Kidney Transplant Practice and Outcomes During Public Holidays in the United States

M. Shamaa, T. Kitajima, T. Ivanics, A. Elsabbagh, M. Lu, K. Delvecchio, A. Mohamed, S. Yeddula, M. Rizzari, K. Collins, A. Yoshida, M. Abouljoud, S. Nagai, *Transplant surgery, Henry Ford Hospital, Detroit, MI*

Purpose: The outcomes of liver transplant (LT) and kidney transplant (KT) have been shown to be unaffected by the time of transplant surgery whether done during weekends, or summer months. The possible effects of public holidays on organ transplant practice and outcomes have not been fully investigated. This study aims to compare the rates of liver and kidney transplant (LT, KT) during public holidays and explore whether post-transplant outcomes differ.

Methods: We assessed the rates of single-organ, deceased LT and KT from 2010-2019 for recipients age ≥18 years using the UNOS database. Public holidays included Easter, Memorial Day, July 4th, Labor Day, Thanksgiving, and Christmas/New-Years (winter holidays). Patients were grouped by transplantation during public holidays ±3 days (LT: n=7640; KT: n=15,143) and non-holiday periods (LT: n=50,129, KT: n=98,313). Risk of graft loss, death-censored kidney graft loss, and mortality at 1-month, 1-year, 3-year, and 5-year were analyzed using multivariable Cox regression models.

Results: KT and LT recipient characteristics were similar between public holidays and non-holidays. The transplant activity did not differ between public holidays and non-holidays for LT (16.6 vs 15.9 transplants/day; p=0.42) and KT (30.9 vs 31.1 transplants/day; p=0.5). In LT donors, the holiday group had the **smaller** proportion of cold ischemia time (CIT) > 8 hr (15.2% vs 17.2%; p<0.001), higher donor risk index (DRI) >1.6 (42.0% vs 43.6%, p=0.009; Table 1A), and smaller proportion of marginal donors (DCD or >70 years, 19.2% vs 21.1%; p=0.001). In KT donors, the holiday group had the larger proportion of younger donors <50 years (73.1% vs 71.5%; p=0.001), shorter CIT ≤16 hr (47.5% vs 46.5%; p=0.021), and Kidney Donor Profile Index ≤0.42 (49.9% vs 48.9%; p=0.027; **Table 1B**). After adjusting for donor and recipient factors, LT during public holidays was associated with a lower risk of 5-year mortality (HR 0.92 [0.86-0.98], p=0.01; **Figure 1**). Regarding KT, similar post-transplant outcomes (graft loss, death-censored graft loss, mortality) were found between holidays and non-holidays.

Conclusions: While LT or KT activity was not affected by public holidays, long-term outcomes in LT performed during public holidays were significantly better compared to the non-holiday group, most likely due to more conservative graft selection.

Donor characteristics for LT (**Table 1A**) and KT (**Table 1B**). **Figure 1**- Kaplan-Meier survival curve for 5-year LT patient survival using cox regression model.

Abstract# 1110

Liver Transplant in Adult Recipients Using Pediatric Deceased Donor Liver Grafts

P. Vargas[1], C. Argo[2], H. Zachary[2], M. Stotts[2], N. Intagliata[2], P. Northup[2], S. Pelletier[1], J. Oberholzer[1], N. Goldaracena[1], *[1]Transplant surgery, University of Virginia, Charlottesville, VA, [2]Gastroenterology and Hepatology, University of Virginia, Charlottesville, VA*

Purpose: The aim of this study is to evaluate the outcomes following liver transplantation (LT) in adults using grafts from a pediatric deceased donor.

Methods: A retrospective, single-center study identifying adult LT using pediatric (≤12 years) deceased donor liver grafts (PD group) was conducted from 2013-2020. A 1:2 case-control match was performed to identify adults receiving a graft from an adult donor ≥18 years (AD group) in the same period based on recipient age (±10 years), model for end-stage liver disease (MELD) score at transplant (±5 points) and indication for LT. Patient data was obtained through electronic medical records chart review. Early complication rates were identified and graded using Dindo-Clavien classification. Graft and patient survival were assessed by Kaplan-Meier curves.

Results: 479 patients were identified. From those, 12 patients received a graft from a deceased pediatric donor and were matched with 24 adults receiving a graft from an adult donor. Recipient mean age, body mass index (BMI), and MELD were similar between groups. Male gender was significantly higher in the AD group compared with the PD group (20 (83.3%) vs 4 (33.3%), p=0.003). Alcohol related cirrhosis was the most common indication for transplant in both groups, followed by hepatocellular carcinoma, seen in 50% and 33.3% of recipients in each group, respectively. As expected, donor mean (SD) age and donor BMI were significantly higher in the AD group (47.13 (± 15.87) vs 8.83 (± 2.72), p=0.001 and 28.70 (± 6.16) vs 17.0 (± 2.67), p=0.032, respectively). Cold ischemia time and warm ischemia time were similar between groups. There was no recipient mortality in the PD group, while one (4.2%) recipient in the AD group died two months after LT. According to Dindo-Clavien classification, no significant difference was found among groups. Three (25%) patients developed minor complications in the PD group, versus 7 (29.1%) in the AD group. Major complications (≥3b) were seen in 4 patients in both groups (33.3% vs 16.7%, respectively). The most common complication was bile duct stricture in both groups, seen in 3 (25%) and 4 (16.7%) recipients in the PD group and AD group, respectively (p=0.55). Hepatic artery thrombosis was seen in 2 patients (16.7%) within the first week, successfully managed by thrombectomy and hepatic artery reconstruction without the need of re-transplantation in the PD group and in one (4.2%) in the AD group, (p=0.2). Graft and patient survival at 1-, 3-, and 5- year were similar among groups for all time periods (100% vs 96%, p=0.48).

Conclusions: We observed an excellent patient and graft survival in liver transplantation with pediatric deceased donor livers into adult recipients. Careful donor recipient matching and close monitoring for potential biliary and vascular complications is crucial to achieve acceptable outcomes.

Liver

Liver: Hepatocellular Carcinoma and Other Malignancies

Abstract# 1111

Given the Potential Impact on Liver Transplant Selection, Revisiting the Current Standard of Diagnosis of Hepatocellular Carcinoma

K. Amarell, B. Fisher, B. Park, K. Ko, B. Kallakury, *Department of Pathology & Laboratory Medicine, Georgetown University School of Medicine, Washington, DC*

Purpose: The current standard of diagnosis of hepatocellular carcinoma (HCC) relies on non-invasive radiographic methods, namely computerized tomography (CT) and/or magnetic resonance imaging (MRI). However, independent studies conducted in Missouri, Belgium, and South Korea have suggested radiology may be insufficient as a stand-alone diagnosis method for HCC. Hence, we investigated the effectiveness of current diagnosis standards of HCC at MedStar Georgetown University Hospital (MGUH).

Methods: We analyzed 130 patients who underwent liver biopsy (n=40), partial hepatectomy (n=28), or liver explant (n=62) at MGUH from December 2017 to June 2019 with a corresponding in-house radiologic study. We compared the pathology reports with their corresponding radiology reports to determine MGUH's effectiveness in detecting HCC based on the current Liver-Imaging Reporting and Data System version 2018 (LI-RADS v2018).

Results: Of the 130 cases analyzed, 118 cases were histologically confirmed HCC, of which 100 were correctly identified on radiology (100/118; 84.7%). The remaining 18 cases of confirmed HCC showed discrepancy with the radiology reports, to include 6 benign (6/18; 33%) and 12 non-HCC neoplasms (12/18; 67%), such as cholangiocarcinoma, lymphoma, and sarcoma, with a total discrepancy rate of 15.3% (18/118). In the residual 12 of 130 cases, 7 were histologically confirmed to be benign (completely normal or bile duct adenoma), of which 5 cases (5/7; 71.4%) were misdiagnosed as HCC by radiology. Our results revealed an overall radiology negative predictive value of 21.7% and a positive predictive value of 93.5% for HCC diagnosis.

Conclusions: Our study provides supporting evidence, in conjunction with several of its contemporary studies, that the current LI-RADS v2018 guidelines require a further amendment to include histologic confirmation of the HCC diagnosis.

Table 1. Comparing pathology and radiology diagnosis of 130 cases analyzed in study

Biopsy (40) / Hepatectomy (28) / Total explant (62)

Abstract# 1112

Pilot Evaluation of Prognosis After Liver Transplantation in Patients with a History of Hepatocellular Carcinoma and Pd-1 Inhibition

M. Chen[1], Z. Chen[1], X. Lin[2], *[1]First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China, [2]the Eastern Hospital of the First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Purpose: The successful applications of programmed death protein-1 (PD-1) inhibitors in cancer therapy has led to an expanding use of immunotherapy in oncolog Liver transplantation (LT) is considered the most effective treatment for end stage liver diseases (ESLD) including HCC. However, the applications of PD-1 inhibitors in cancer patients would be controversial with LT. In this article, we have firstly described the clinical characteristics, imaging findings, and outcomes of 5 LT patients who had a History of HCC and PD-1 Inhibition.

Methods: Data of 5 cases who were diagnosed with HCC and received a LT after applications of PD-1 inhibition were analyzed. Doses and cycles of PD-1, preoperative and postoperative characteristics were compared and analyzed.

Results: The mean time difference between the last treatment of PD-1 inhibition and LT was 63.80±18.26 days. One patient had a recurrence in liver, vertebrae and lungs after 7 months. All patients displayed normal liver function in the latest follow-up. No acute allograft rejections were occurred in all patients.

Conclusions: PD-1 inhibitor may be safe to be used tin the treatment of HCC before LT when the time difference is sufficient. Further investigations are needed for any convincing results.

Abstract# 1113

Effects of TIPS on Transplant Outcomes for HCC

C. L. Hanlon[1], D. Toy[1], Y. Liu[1], S. Zhou[1], K. Zhou[2], J. Kahn[2], L. Yuan[2], *[1]Internal Medicine, University of Southern California, Los Angeles, CA, [2]Internal Medicine - Department of Gastroenterology and Hepatology, University of Southern California, Los Angeles, CA*

Purpose: The purpose of this study is to examine effects of TIPS placement on response to locoregional therapy (LRT) and clinical outcomes after liver transplantation in HCC patients.

Methods: Adults who had TIPS placed prior to HCC diagnosis who underwent LT for HCC at a single center from 2014-2020 were included. Presence of TIPS and LRT response were collected from chart review of multi-phase cross-sectional abdominal imaging prior to LT, and tumor characteristics were collected via explant pathology. Clinical outcomes were assessed. Covariates of interest included age, sex, etiology of HCC, body mass index, MELD-Na after LRT, timing from TIPS to LRT, number of LRT treatments, and timing from HCC diagnosis to LT.
Results: Of 303 patients who underwent LT for HCC at a single center from 2014-2020 and met eligibility for the study, 13 (4.3%) had TIPS placed prior to diagnosis of HCC, and 1 (0.03%) had TIPS placed while undergoing LRT but prior to LT. Of the 13 patients with TIPS prior to HCC diagnosis, the mean age at HCC diagnosis was 60.4 years, and the sample was 92.3% male (12 of 13). 10 (76.9%) patient received at least one LRT prior to LT, and 5 (38.5%) underwent 2 or more LRTs. Post-LT survival among patients with TIPS was excellent, with 100% survival rate and no HCC recurrence on follow up imaging. Zero TIPS patients displayed post-LT hepatic vasculature complications within 1 year of LT. Calculated RETREAT scores ranged from 0 to 2, with the most common score being 1 (76.9% [n=10]). Overall post-transplant HCC-free survival and post-transplant complication rates were superior to overall HCC transplant data at the center (100% 3-yr survival with a functioning graft vs 87.34% expected 3-yr survival with a functioning graft unadjusted for patient and donor characteristics).
Conclusions: Presence of TIPS does not appear to increase post-LT complications, nor does TIPS affect HCC recurrence and recurrent-free survival. Overall post-transplant HCC-free survival and low post-transplant complication rates may be attributable to tumor biological behavior, low AFP, and low RETREAT scores among HCC patients with TIPS.

Characteristic	Patients with TIPS prior to HCC (N=13)
Age at HCC diagnosis (yr)	60.4 (63.2 - 56.9)
Indication for TIPS	
Refractory ascites	4
Acute variceal bleed	8
Recurrent variceal bleeding	2
TIPS placement to HCC diagnosis (days)	678 (242 - 1653.5)
HCC diagnosis to LT (days)	493 (248 - 631.5)
Median largest viable lesion (cm)	2.30 (2.00 - 3.30)
RETREAT Score	
0	2
1	10
2	1
Survival to date	13 (100%)
Median post-LT survival (yr)	4.4 (3.1 - 4.7)

Abstract# 1114

Immunotherapy of Dc-cik Cells in Patient with Hepatocellular Carcinoma Recurrence Following Liver Transplantation

S. Hsu, L. Jeng, H. Yang, A. Thorat, *China Medical University Hospital, Taichung, Taiwan*

Purpose: Dendritic cells (DCs) and cytokine-induced killer (CIK) cells, components of anti-cancer therapy, have shown clinical benefits and potential to overcome chemotherapeutic resistance in some cancer patients. However, only fewer experience published about the safety and efficacy of DC/CIK in the transplant patients. We would like to share our experiences of DC/CIK therapy in the transplant patients.
Methods: Until November 12th, 2020, 8 patients receiving DC/CIK therapy for hepatocellular carcinoma recurrence or metastasis (Table 1). 6 patients already received liver transplantation, but another 2 patients did not. 6 patients already completed DC/CIK treatment courses and another 2 patients are processing. Almost all patients even received other therapies, like checkpoint inhibitor, target therapy, trans-arterial chemoembolization or radiotherapy. Images and laboratory data are used to evaluate the patient's response.
Results: Of 6 patients with complete DC/CIK therapy, the survival days are 58 days to 184 days. Images and laboratory data approve 1 patient with complete responses (CR). 1 patient is approved as partial response (PR), and 3 patients stay with stable disease (SD). 1 patient is approved as progressive disease (PD). 2 patients already died because of infection and disease progression later. No patient develops any rejection or cytokine release syndrome.
Conclusions: Multidisciplinary therapy is a favored treatment option for HCC patients now right, like checkpoint inhibitor therapy and target therapy together or local treatment and target therapy. However, checkpoint inhibitor is still relatively contra-indication to the transplant patient because of potential graft rejection. Thus, DC/CIK could be another alternative therapy. In our experiences, DC/CIK is safe and has potential efficacy in the transplant patient.

No.	Age / Gender	History	Response (until Nov. 12th, 2020)	Status/survival days (since last DC/CIK therapy)	Cause of Death
1	57/M	• LDLTx before and then recurrence and metastases • DC/CIK Combine with target therapy and Anti-PD-1 therapy.	Stable disease (SD)	Alive / 184 days	-
2	61/M	• LDLTx before and then recurrence and metastases • DC/CIK Combine with TACE and local radiotherapy of LN metastases	Stable disease (SD)	Alive / 181 days	-
3	61/M	• DDLTx and then recurrence and metastases • Received tumor excision • DC/CIK Combine with TACE, target therapy and Anti-PD-1 therapy	Stable disease (SD)	Death/ 117 days	Infection
4	54/M	• LDLTx and then intrahepatic recurrence • DC/CIK Combined with TACE	Complete response (CR)	Alive / 127 days	-
5	45/M	• No LTx • Hepatectomy, TACE and target therapy before • Did not combine with other therapy	Partial response (PR)	Death / 58 days	Liver failure
6	39/F	• No LTx or hepatectomy • DC/CIK Combine with Anti-PD-1 therapy and target therapy, clinical trial	Progressive disease (PD)	Alive / 114 days	-

Abstract# 1115

Impact of Donation After Circulatory Death Donor Allografts on Outcomes Following Liver Transplantation for Cholangiocarcinoma

S. Kumar[1], S. Lin[2], J. D. Schold[2], *[1]Digestive Disease Institute, Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates, [2]Department of Quantitative Health Sciences, Cleveland Clinic Foundation, Cleveland, OH*

Purpose: Improvements in the management of extra-hepatic cholangiocarcinoma (CCA) resulted in allocation of a standardized model for end-stage liver disease (MELD) exception score for liver transplantation (LT) in 2009 for selected patients who completed an approved neoadjuvant chemoradiation protocol. Limited data exists regarding donation after circulatory death (DCD) grafts in CCA despite higher reported incidence of biliary complications. We compared outcomes following DCD LT in CCA (DCD-CCA) with deceased donor (DBD-CCA) and living donor LT (LDLT-CCA), as well as DCD in Hepatocellular carcinoma (DCD-HCC) and indications other than HCC or CCA (DCD-non-CCA/HCC).
Methods: Using SRTR, retrospective study cohorts were constructed over the time period 2009-2019. Primary outcome measures were graft and patient survival. A chi-square test was used for categorical and Student's t-test for continuous variables. Survival comparison was performed using the Kaplan-Meier method with log-rank test and multivariable analysis of outcomes using Cox proportional hazard models.
Results: 425 recipients underwent LT for CCA over the study period: DCD-CCA: 36 (8.5%), DBD-CCA: 361 (85%), LDLT-CCA: 28 (6.5%). 884 and 3101 recipients respectively underwent DCD-HCC and DCD-non-CCA/HCC. All CCA groups were comparable with respect to donor, recipient variables, cold ischemia time (except LDLT-CCA) and time from listing to LT. Mean lab MELD in DCD-CCA was lower than DBD-CCA (12.9 vs 14.3, p=0.02) and DCD-non-CCA/HCC (12.9 vs 19.6; p<0.0001), but comparable to DCD-HCC (12.9 vs 13; p=0.27). Observed graft survival in DCD-CCA was lower than DBD-CCA and LDLT-CCA (Fig 1). However patient survival in the 3 CCA groups was comparable: DCD-CCA, DBD-CCA, LDLT-CCA (%): 1 Yr: 82.2 vs 89.2 vs 88.7; 3 Yr: 64.4 vs 65.1 vs 75.4; 5 Yr: 55.8 vs 55.1 vs 67.9 (p=0.44). Outcomes in DCD-CCA were also inferior to DCD-HCC and DCD-non-CCA/HCC. On multivariable analysis, while cold ischemia time was predictive of both graft and patient survival in CCA, recipient DCD status was only predictive of graft (HR (95% CI): 1.69 (1.03-2.76), p=0.03), but not patient survival (HR (95% CI): 1.39 (0.81-2.37), p=0.22).
Conclusions: Even though graft survival following DCD LT in CCA is inferior to DBD and LDLT, patient survival is comparable. Consideration of DCD in CCA may confer a survival advantage when weighed against likelihood of wait-list drop out in carefully selected recipients with a time-sensitive need for LT.

Abstract# 1116

Review of 10-Year Liver Explant Pathology Impact on Outcomes in a Single Center

Y. K. Kwon[1], L. Sher[1], S. Khemichian[2], J. Kahn[2], Y. Genyk[1], *[1]Hepatobiliary and Abdominal Transplant Surgery, University of Southern California, Los Angeles, CA, [2]Gastrointestinal and Liver Diseases, University of Southern California, Los Angeles, CA*

Purpose: Explant pathology (EP) is an important prognostic factor after liver transplantation (LT) for hepatocellular carcinoma (HCC). The purpose of this study was to correlate EP findings with outcomes following LT over a 10-year period in a region 5 institution.
Methods: All LT cases with HCC on EP from Jan. 1, 2010 through Dec. 31, 2019 were identified. Retrospective review was conducted and the following data collected: EP including size, number, histology and differentiation of the tumor(s) as well as the presence of lymphovascular invasion. Additional data included patient demographics, pre-operative imaging and outcomes. Survival was analyzed using the standard Kaplan-Meier method. Separate analysis was conducted for patients in whom HCC was an incidental finding.
Results: 285 patients met the above inclusion criteria including 19 (6.7%) who did not have a formal diagnosis of HCC pre-operatively. Among the 19 patients, 3 had suspicious lesions, 1 had an elevated serum alpha-fetoprotein with a negative imaging study, and the remaining 15 patients had no evidence of HCC. Among the 16 patients with no radiographic lesions, the incidental tumor on explant was small (Median 1.2cm, Average 1.3cm [0.8cm to 2cm]) with the median value of one tumor per patient (average 1.5). 6 patients had well-differentiated HCC, and the remaining 10 had moderately differentiated HCC. Overall, these 19 patients had an excellent survival when compared to all the study patients as a group (Figure 1). Among the 285 explants, 239 met Milan criteria (MC), and 46 patients did not for the following reasons: lymphovascular invasion (n=20), number and/or size of tumors or local direct invasion (n=14), and non-HCC tumors (n=12). Patients who met the MC had 1 and 5-year survivals of 95% and 90% compared to 78% and 62% for those who did not meet the MC ($p < 0.0001$) (Figure 2). Survival analysis of the 3 sub-groups showed that those patients with non-HCC or microscopic invasion had a significantly worse outcome than those who did not meet the MC due to the tumor's macroscopic features alone (Figure 3).
Conclusions: Incidental HCC on EP did not appear to have a negative survival impact likely due to the early nature of the cancer disease. Among the patients who did not meet the MC, those with non-HCC or microscopic invasion had a worse outcome, suggesting that tumor biology and evidence of microscopic invasion are more critical prognostic factors than macroscopic aspects of the tumor including direct local extrahepatic invasion.

Abstract# 1117

Intrahepatic Spatial Location of HCC Recurrence Following Loco-regional Therapy for Solitary Tumors Predicts a Higher Oncologic Risk & Increased Recurrence Post-transplant

A. Mathur, E. Baughan, S. Haider, A. Griesemer, T. Kato, J. Emond, *Columbia University, New York, NY*

Purpose: Loco-Regional therapy (LRT) for hepatocellular carcinoma (HCC) patients is an established bridge to Orthotopic Liver Transplantation (OLT). However, no large cohort data exist correlating patterns of spatial recurrence within the liver Post-LRT and HCC recurrence post-transplant. Recurrences in segments away from the original tumor would represent de-novo HCC or intra-hepatic spread. Intuitively, this pattern of recurrence would represent a higher oncologic risk than patients that recur in the same or adjacent areas of the liver. Patients with solitary tumors represent an ideal group to evaluate this response. Therefore, we hypothesized that patients with solitary tumors undergoing LRT that have recurrences of HCC away from the original segment of the tumor carry a higher oncologic risk & increased recurrence post-OLT.
Methods: From a database of 645 patients who had OLT for HCC we identified 508 patients who had LRT pre-OLT. 74 had cancer recurrence post-OLT. Of these 20 cases had a single tumors within Milan criteria pre-first LRT. We matched them with patients who did not have a recurrence post-OLT based on etiology, MELD, AFP and tumor size pre-first LRT. Tumor data was recorded after reviewing imaging pre-and post- each LRT as well as pre-transplant. Demographics, etiology, AFP and NLR (at each LRT), and explant tumor pathology post-OLT was recorded.
Results: Median age of all patients was 59years and 74% were male. Neutrophil-Lymphocyte ratio (NLR) was no different prior to 1st LRT between groups (2 +/- 1 vs. 2 +/- 1) but was significantly higher pre-OLT in recurrers (5+/-6 vs 2+/-1; p=0.05). Median AFP levels of both groups was 25 pre-LRT and stayed unchanged pre-OLT. No differences existed in mean number of LRTs between groups (2 +/- 1 vs. 2 +/- 1) . Percent patients with >=3 LRTs was 36% vs 39% in Recurrers and Controls respectively. However, location of recurrence was distant from tumor in a greater proportion of recurrers (50%vs 12,5%, p=0.07). Explant pathology showed higher grade (82% vs 28%, p<0.05) and larger tumor size (5+/-2 vs 3+/-2; p<0.05) in recurrers. Interestingly, on explant only 50% of recurrers and 59% of non-recurrers had single tumors.
Conclusions: These data show that HCC patients with solitary lesions within Milan criteria need multiple LRTs and the number of LRTs do not predict who recurs. However, a pattern of recurrence distant from the original tumor bearing segment of the liver is present in patients that recur. Patients with these patterns of recurrence have higher tumor grade on final pathology. Finally, while an altered immune response, represented by NLR, was not present pre-LRT -patients that develop distant liver segment recurrences generate an elevated NLR. Therefore, we conclude that patients with solitary tumors undergoing LRT that have recurrences away from the original segment of involved tumor carry a higher oncologic risk & increased recurrence post-OLT.

Abstract# 1118

Improving Liver Transplantation Outcomes for Hepatitis C Associated Hepatocellular Carcinoma in Direct-Acting Antiviral Therapy Era

K. Okumura, H. Sogawa, G. Veillette, D. John, T. Diflo, R. Bodin, D. C. Wolf, S. Nishida, *Surgery, Westchester Medical Center/New York Medical College, Valhalla, NY*

Purpose: Direct-acting antiviral (DAA) therapy has transformed the outcomes of liver transplantation(LT) in patients with hepatitis C virus (HCV). The aim of this study was to analyze the effect of DAA treatment for HCV-associated hepatocellular carcinoma (HCC) in LT.
Methods: We analyzed data from the United Network for Organ Sharing between 2012-2016. We defined as pre-DAA era between 2012-2013 and DAA era between 2014-2016. We included the patients confirmed as HCC on explant and evaluated demographics and the tumor features on explant of HCC during the study periods.
Results: 7,716 liver transplants for HCC were performed during the study periods and HCV-associated HCC were 4,778 (62%). In DAA era, median recipient age was older and median days of waiting list were longer (61 vs 59; 258 vs 222 days p<0.01, respectively). Pre-LT treatment rate was higher and AFP before transplant was lower (95.8 vs 92.8 %; 13 vs 8 ng/ml p<0.01, respectively). For donor, median donor's age, donor BMI and rate of HCV significantly increased in DAA era (42 vs 41; 26.9 vs 26.6; 13.9% vs 9.1%, p<0.01, respectively). In pathology, there was no significant difference in high risk features (p=NS), however, rate of completed tumor necrosis was significant higher in DAA era (20.6 vs 15.8%, p<0.01). Compared to pre-DAA era, one-year graft survival and patient survival were same (90.7% vs 89.7%; 90.8% vs 89.8%, p=NS, respectively), however, three-year graft survival and patient survival had significantly improved in DAA era. (85.0% vs 80.8%; 86.9% vs 83.3%, p<0.01, respectively). In cox regression multivariable analysis, DAA era

(hazard ratio [HR], 0.79; p<0.01), pre-LT diabetes (HR, 1.31; p<0.01), high AFP per 100 (HR, 1.03; p<0.01), high MELD score per 10 (HR, 1.16; p=0.04), histologic grade (HR 1.29; p<0.01), high risk features (HR, 1.70; p<0.01), and high DRI (HR, 1.50; p<0.01) had significantly impacted for three-year graft survival. Pre-transplant treatment and donor HCV status did not affect the outcomes.

Conclusions: DAA has a significant impact of LT. In DAA era, graft survival and patient survival for HCV associated HCC have been significantly improving.

Abstract# 1119

The Role of Histone Acetylation/methylation Mediated Epigenetic Modifications in the Pathogenesis of Non-alcoholic Steatohepatitis-associated Liver Carcinogenesis

P. K. Rajan[1], U. Utibe-Abasi[1], J. D. Sanabria[1], M. Banerjee[2], G. Smith[1], M. S. Schade[1], J. Sanabria[1], K. Sodhi[1], S. Pierre[2], Z. Xie[2], J. I. Shapiro[2], J. Sanabria[1], *[1]Department of Surgery, Marshall University, Huntington, WV, [2]Marshall Institute for Interdisciplinary Research (MIIR), Marshall University, Huntington, WV*

Purpose: Hepatocellular carcinoma (HCC) is one of the most aggressive human cancers and is characterized by an acquisition of multiple abnormal phenotypes driven by epigenetic alterations. Epigenetic changes including histone modifications are associated with uncontrolled cell growth and proliferation, and even initiation and progression of HCC from chronic inflammation with or without fibrosis in the liver. Among others, NASH and ASH are two major risk factors as both of them may develop cirrhosis and HCC if left untreated. Most of the existing clinical and experimental reports provide only a snapshot of abnormal histone modifications in HCC rather than their dynamic changes. This makes it difficult to elucidate the significance of these changes in the development of HCC. In the present study, we investigated the role of histone acetylation/methylation mediated alterations using in vitro cell line and high fat diet animal model of NASH-derived liver carcinogenesis.

Methods: In vitro studies were done using hepatocellular carcinoma cell lines, HEP3B and SNU 475, treated with different doses of pNaKtide at different time points. C57BL/6 female mice were exposed to normal mouse chow (NMC), HFD and HFD± pNaKtide for 24 weeks. HCC mice were exposed to graded doses of pNaKtide. The acetylated and tri methylated H3K9 in cell lysates and liver homogenates were quantitatively measured by ELISA. Expression of H3acetylK9 and H3tri-methyl K9 proteins were performed by confocal-microscopy on immuno-stained livers from HCC and NASH. Significant differences among groups were established at p<0.05 using ANOVA/t-test.

Results: The amount of acetylated and tri methylated H3K9 were found to be significantly increased in untreated hepatocellular carcinoma cells and were significantly decreased by pNaKtide treatment. In line with these in vitro results, the increased amount of acetylated and tri methylated H3K9 in the liver of NASH and HCC mice were found to be significantly decreased by pNaKtide administration. The immunofluorescence analysis of H3acetylK9 and H3tri-methyl K9 proteins further confirmed our findings.

Conclusions: In summary, the pivotal role of concurrent activation of acetylation and tri methylation of H3K9 in the pathogenesis of NASH associated HCC, as evidenced by our findings, explore their potential for translation into therapeutics by epigenome reprogramming.

Abstract# 1120

Excellent Pathological Response with Gemcitabine-based Protocol in Patient with Hilar Cholangiocarcinoma

A. Saharia[1], R. McMillan[1], S. Kodali[1], M. Javley[2], C. M. Mobley[1], M. J. Hobeika[1], A. Shetty[1], D. W. Victor[1], R. McFadden[1], M. Abdelrahim[1], K. Heyne[1], A. O. Gaber[1], R. M. Ghobrial[1], *[1]Houston Methodist Hospital, Houston, TX, [2]MD Anderson Cancer Center, Houston, TX*

Purpose: The standard treatment for hilar cholangiocarcinoma is using 5FU along with brachytherapy and external beam radiation. The downside of this regimen is the uncertain timing of radiation which makes the hilar dissection challenging. Gemcitabine and platinum-based therapy has emerged as a standard of care for cholangiocarcinoma. We looked into the pathological response to treatment using this regimen in our past 5 consecutive patients.

Methods: A retrospective analysis of the 1) mode of diagnosis 2) duration of induction with gemcitabine and cisplatin 3) duration of maintenance treatment with either gemcitabine or with capecitabine and 4) pathological response to treatment in the explanted liver was made.

Results: The five patients received gemcitabine-platinum and no external beam radiation. All patients maintained disease stability and underwent deceased donor liver transplantation based on the UNOS criteria for hilar cholangiocarcinoma. The patients had excellent pathological response to treatment.

Conclusions: The availability of radiation free, gemcitabine/ platinum based protocol gives us an additional tool in the management of hilar cholangiocarcinoma. Single agent gemcitabine or capecitabine are safe to give for long term maintenance. If the long term outcomes parallels that of Mayo protocol, this may become the standard of care. This protocol may have higher surgeon acceptability because it offers a radiation free surgical field.

Abstract# 1121

Liver Transplantation Following Checkpoint Inhibitor Therapy - Timing is Everything

G. T. Schnickel[1], J. Parekh[1], Y. Kono[2], J. Berumen[1], V. Ajmeera[2], K. Mekeel[1], *[1]Division of Transplant and Hepatobiliary Surgery, Department of Surgery, University of California San Diego, San Diego, CA, [2]Division of Gastroenterology, Department of Medicine, University of California San Diego, San Diego, CA*

Purpose: Use of checkpoint inhibitors (CPI) prior to liver transplantation has not been well studied and limited case reports describe a risk of early graft failure secondary to immune mediated hepatic necrosis. However, with CPIs approved as first line therapy for unresectable hepatocellular carcinoma (HCC), the number transplant recipients receiving treatment with CPIs will increase. Therefore, we aimed to explore the association between time from last CPI administration and allograft outcomes in a case series of three liver transplant recipients.
Methods: We reviewed the charts of patients that received liver transplantation following treatment with checkpoint inhibitor therapy for HCC between January 1, 2018 and November 1, 2020. All transplants were performed with caval sparing technique and received standard three-drug immunosuppression of steroid taper, tacrolimus, and mycophenolate mofetil. Two patients received induction with rATG 3mg/kg. All biopsies were reviewed by a single pathologist and rejection classified by Banff criteria.
Results: Three patients underwent liver transplantation after receiving CPI therapy for HCC. All three patients received Nivolimab 240mg every 2 weeks the first month, then 480mg every 4 weeks thereafter. Time from last dose of CPI to transplant ranged from 10 days to 3 months. The 2 patients with less than 3 months from last dose of CPI to transplant developed ACR and substantial hepatic necrosis. Patient A's graft was salvaged after treatment with steroids, 9mg/kg rATG + rituximab. Patient B was re-transplanted for graft failure after failing treatment with steroids, rATG, and plasmapheresis. This patient also developed significant early ACR after re-transplant. Patient C with three months from last dose of CPI to transplant had consistent excellent graft function with no episodes of ACR.
Conclusions: Pretransplant use of CPI therapy for HCC confers a high risk for acute cellular rejection, antibody mediated rejection and immune mediated hepatic necrosis, which can lead to a high risk of graft loss and patient death. Time from the last dose of CPI to transplant may mitigate the risk for adverse immune mediated outcomes and a waiting period of at least 3 months warrants further evaluation.

Recipient Characteristics/outcomes			
	A	B	C
Duration of CPI	8 months	18 months	8 months
Time from last CPI to transplant	10 days	5 weeks	3 months
Time to biopsy	14 days	12 days	n/a
Biopsy results	ACR5/9, 20%necrosis	ACR 4/9, 60%necrosis	n/a
Treatment	rATG, steroids, rituximab	rATG, steroids, plasmapharesis	n/a
graft outcome	salvaged	re-transplant	stable function
patient outcome	alive	alive	alive

Abstract# 1122

Albumin Level Prior to Liver-Directed Therapy is a Risk Factor of Waitlist Tumor Progression Independent of HCC Burden

P. Thevenot, K. Nunez, T. Sandow, M. Hibino, P. Wright, J. Patel, D. Fort, A. Cohen, *Ochsner Health, New Orleans, LA*

Purpose: Milan Criteria, α-fetoprotein (AFP), and MELD score at diagnosis influence prognosis in bridge to transplant (BTT) hepatocellular carcinoma (HCC). With HCC surveillance many patients are diagnosed within Milan with both low AFP and MELD. Albumin level decreases in the progression of cirrhosis-associated immune dysfunction toward a state of immune paralysis, which may have important implications liver-directed therapy (LDT). In this study, we examine albumin as a risk factor for tumor progression following LDT, particularly in ideal BTT patients within Milan with a low AFP.
Methods: Retrospective study of patients receiving first-line LDT as a BTT within a single system (April 2016 - March 2020). Parameters were analyzed prior to first-line LDT and patients monitored for BTT survival and BTT outcome.
Results: Analyzed were 294 treatment naive HCC patients with median age of 63 years (IQR 59 - 66 years) and demographics of 75% male with predominant hepatitis C etiology (66%). Patients were 80% within Milan with 69% having an AFP ≤ 50 ng/mL. Study endpoint was reached in 186 patients: 33% transplanted, 30% dropout due to tumor progression, with 25% censored and 12% waitlist active at data analysis. Albumin level stratified 0.3 g/dL tiers from < 2.9 g/dL to > 3.8 g/dL revealed that lower albumin levels directly correlated with history of decompensation requiring intervention (P<0.001) with incremental rise in MELD-Na score with decreasing albumin tier (P<0.001). However, there was no association between albumin level and Milan status (P=0.121) or AFP level (P=0.377). In multivariate analysis controlling for Milan and AFP, albumin level was independently associated with BTT survival (HR 0.79, 95% CI 0.66 - .93) and BTT outcome (OR 0.70, 95%CI 0.53 - 0.92). In patients within Milan with an AFP < 50 ng/mL, albumin ≤ 3.1 g/dL was associated with a significant decrease in bridge to transplant survival (P = 0.001).
Conclusions: Low serum albumin at HCC diagnosis identifies patients with high risk of post-treatment tumor progression. This increased risk may be due to immune paralysis in cirrhosis-associated immune dysfunction.

Abstract# 1123

Outcomes of Surgical Resection versus Liver Transplantation in Hilar Cholangiocarcinoma

M. K. White[1], F. Aucejo[2], A. Moro[2], K. Sasaki[2], K. Stephans[3], B. Estfan[4], C. Quintini[2], B. Eghtesad[2], K. Hashimoto[2], F. Masato[2], C. Miller[2], K. Menon[5], *[1]Cleveland Clinic, Cleveland, OH, [2]General Surgery, Cleveland Clinic, Cleveland, OH, [3]Radiation Oncology, Cleveland Clinic, Cleveland, OH, [4]Oncology, Cleveland Clinic, Cleveland, OH, [5]Gastroenterology & Hepatology, Cleveland Clinic, Cleveland, OH*

Purpose: To compare the outcomes of patients with hilar cholangiocarcinoma (hCCA) who underwent either surgical resection or liver transplantion (LT).

Methods: All hCCA patients who underwent resection or LT between 2010-2020 were included. Standard diagnostic criteria for hCCA were used. Surgical resectability was based on the likelihood of R0 resection and extent of tumor invasion into bile ducts (up to the second order branching)and vessels. Patients with nonresectable tumors underwent the LT protocol with neoadjuvant chemoradiation/brachytherapy, staging laparotomy and maintenance chemotherapy until LT. For LT , the lesion had to be located at the hilum with stricture above the cystic duct, with no evidence of metastasis, mass lesion less than or equal to 3cm and negative regional lymph node biopsies on endoscopic ultrasound. Survival of patients was evaluated with Kaplan Meier curves.

Results: Twenty-six patients underwent surgical resection of hCCA and 22 patients underwent the LT protocol with 15 (68%) undergoing LT. Of the patients who underwent surgical resection, 13 (50%) are still alive. Sixteen (73%) patients who were enrolled in the LT protocol are alive and 14 (93%) patients who underwent LT are alive. On an intention to treat analysis, Kaplan Meier analysis showed no difference in survival between the two groups. However, there was a significant improvement in survival in patients who underwent LT compared to resection (93% vs 50% probability of survival at 5 years, P=0.04).

Conclusions: Patients who complete the neoadjuvant chemoradiation protocol and undergo LT have a significantly higher a survival rate compared to those undergoing resection. However, on an intention to treat basis, the overall survival of patients undergoing the LT protocol is comparable to patients who undergo surgical resection. All patients with unresectable hCCA may benefit from neoadjuvant chemoradiation followed by LT.

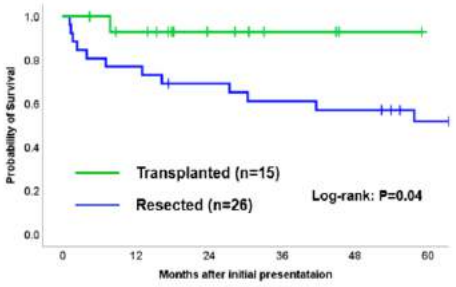

FIGURE 2. Kaplan-Meier curve showing overall survival of patients who underwent tumor resection compared to patients who completed the LT protocol to transplant.

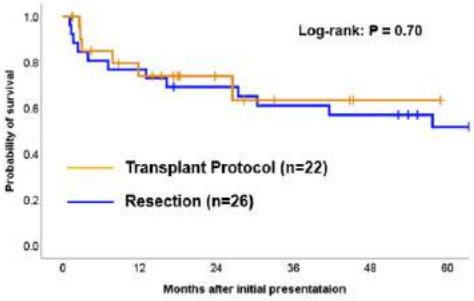

FIGURE 1. Kaplan-Meier curve showing overall survival of patients with hCCA who underwent tumor resection compared to patients who entered the LT protocol.

Liver

Liver: Hepatobiliary Surgery

Abstract# 1124

The Surgical Experience and Treatment Options for Hepatic Cystic Disease

M. Crowley[1], K. Robichaux[2], A. Kumar[1], J. Buggs[3], J. Sokolich[4], *[1]Morsani College of Medicine, University of South Florida, Tampa, FL, [2]Honors College, University of South Florida, Tampa, FL, [3]Transplant Surgery, Tampa General Hospital, Tampa, FL, [4]Hepatobiliary Surgery, Valley Presbyterian Hospital, San Fernando Valley, CA*

Purpose: Benign hepatic cysts may require surgical removal when symptomatic particularly in the setting of genetic disorders such as autosomal dominant polycystic kidney disease (ADPKD) or autosomal dominant polycystic liver disease (PCLD) which may also be called isolated PLD. Operations for symptomatic hepatic cysts can include liver transplantation. The purpose of this study was to compare outcomes in patients with hepatic cysts treated with liver transplantation and or fenestration.

Methods: A retrospective chart review was conducted which included all patients treated surgically for hepatic cystic disease at a single center from June 2011 to May 2020. Treatment groups were divided into those that received fenestrations versus liver transplants. Data were obtained from electronic health records and analyzed with IBM-SPSS version 26. Statistical significance was set at a p-value of less than 5%.

Results: A total of 35 patients were included, 26 underwent fenestration, and 9 had liver transplantation. There were no significant differences in sex, race, age, or BMI between the fenestration and transplant groups. Creatinine and MELD scores were significantly higher in the transplant arm (p<.039, .021 respectively). All transplant patients had ADPKD and greater than 5 cysts removed. Only half the fenestration group had ADPKD, and 27% had greater than 5 cysts removed. The 30-day complication rate was higher in the transplant group (33%) vs. fenestration (4%). The complications included bile leaks, respiratory distress, and exploratory laparotomy. Five (19%) fenestrations required more than one operation and only one (4%) of the 5 patients had ADPKD.

Conclusions: Cyst fenestration and liver transplants may be used to treat symptomatic liver cysts. Liver transplantation is typically reserved for patients with genetic disorders such as ADPKD and isolated PLD, which are associated with a large number of cysts. Patients with ADPKD, even those that require kidney transplants make excellent candidates for fenestration when applicable.

Abstract# 1125

Admission to the Intensive Care Unit Post-liver Transplantation: One Academic Center's Experience

C. D. Santos, A. Grek, T. Krider, *Transplant Critical Care, Mayo Clinic, Jacksonville, FL*

Purpose: Historically, liver transplant (LT) patients have been admitted directly from the operating room (OR) to the intensive care unit (ICU) for post-operative complex hemodynamic and respiratory monitoring. For nearly two decades, our institution has utilized a fast-track program in which select LT patients are extubated in the OR and admitted to the post anesthesia care unit (PACU) followed by subsequent admission to the medical ward. Those patients who require intraoperative continuous

renal replacement therapy (CRRT), diagnosed with Hepatopulmonary Syndrome (HPS) or Porto-pulmonary Hypertension (PoPH) are automatically transferred to ICU post-operatively. Here we describe the profile of our LT patients admitted directly to the ICU from the OR post-LT over the past year.

Methods: A review of the electronic medical record was performed for all liver transplant patients who were admitted to the ICU post-operatively from October 1, 2019 to October 1, 2020.

Results: During the above timeframe, 113 adult deceased donor LTs were performed, 78 (69%) of which were admitted to the ICU post-operatively. Of those admitted to the ICU, 11 received simultaneous liver-kidney transplants, 1 received a simultaneous liver-heart transplant, and 6 received simultaneous LT and sleeve gastrectomy. Of the remaining 60 LT cases, the top three reasons for post-operative admission to the ICU included: post-operative vasopressor requirements or hemodynamic instability in 44 (73.3%) cases, intra-operative continuous renal replacement therapy (CRRT) in 17 (28.3%) cases, and pre-operative ICU admission in 11 (18.3%) cases. Alternative reasons for OR to ICU transfer included: intra-operative bleeding (6, 10%), reintubation or inability to extubate (3, 5%), intra-operative cardiac arrest (2, 3.3%), HPS(2, 3.3%), PoPH (1, 1.7%), and uncontrolled hypertension (1, 1.7%). The majority of OR to ICU cases received donations by brain death (51, 85%) with an average intra-operative transfusion requirement of 8.75 units of red blood cells (median 8 units).

Conclusions: We aimed to understand those defining patient characteristics which required admission to the ICU to better understand if there are modifiable risk factors to minimize ICU admissions with the goal of better utilizing ICU beds during the COVID 19 pandemic. Further research is necessary to determine safety in moving those patients with intraoperative CRRT to the floor rather than an automatic ICU admission.

Machine Learning Informs Utility-Based Non-Directed Living Liver Donor Allocation

K. Bambha[1], J. Perkins[1], M. Sturdevant[1], S. W. Biggins[1], R. Bakthavatsalam[1], P. Healey[2], A. Dick[2], J. Reyes[1], *[1]University of Washington, Seattle, WA, [2]Seattle Children's, Seattle, WA*

Purpose: To maximize non-directed living liver donor graft utility, we developed analytic models predicting 10-year graft survival post liver transplant (LT).

Methods: We analyzed OPTN living liver donor and recipient data (1/2000-12/2019), with follow up to 3/2020. Data included: liver graft type (partial right, partial left, partial left lateral [segments 2&3]), 7 donor & 21 recipient factors, CIT, and donor-to-recipient body surface area (BSA) ratio. To accommodate data complexity with many variables and interactions, we constructed random forest survival models predicting 10-year graft survival for each of the 3 graft types, and variable selection to optimize the c-statistic. Data for each graft type was split into training and test sets. Survivals for predicted groups were calculated by Kaplan-Meier analyses.

Results: The data included 6328 live liver donors (4621 partial right, 644 partial left, 1063 partial left lateral). Of these, 21% (n=1328) were adult to child, 79% (n=5000) were adult to adult. Most partial left lateral grafts (95%) went to children, and the majority of partial right grafts (98%) went to adults. Donor-to-recipient BSA ratio was an important survival predictor in all 3 graft type models (degree of importance in the models was: partial left lateral>partial left>partial right). Variables common to all 3 graft types were: malignant diagnosis, medical location at the time of LT (inpatient/ICU), and moderate ascites. Biliary atresia diagnosis was of high importance in partial left and left lateral graft models, but of no importance in the partial right graft model. Re-transplant status was only important in the partial right graft model. The best c-statistic was 0.70 for the partial left lateral model, and 0.63 and 0.61 for partial left and partial right models, respectively.(Fig. 1) To compare model predictions to actual survival, the 10-year graft survival predictions were stratified into upper quartile versus the combined lower quartiles. The upper quartile group in each model had significantly better 10-yr graft survival than the lower quartile groups, ($p<0.005$).

Conclusions: Our utility-based models identify and stratify potential recipients for non-directed living donor livers based on the predicted 10-year graft survivals, while accounting for complex donor-recipient interactions. There is an unmet need for evidence to help guide living liver donor programs to more objectively allocate non-directed living donor livers, and these analyses set the stage for further investigation into this important area.

Abstract# 1127

Elevated BMI (>28) and High Titer ANA are the Most Common Causes of Abnormal Selective Pre-donation Liver Biopsies in Living Liver Donors

J. Cisek, *Transplant, University of Colorado Hospital, Aurora, CO*

Purpose: The aim of this study is to assess the diagnostic yield of selective pre-donation liver biopsy in living donor liver candidates and its impact on donor selection.

Methods: We reviewed all liver biopsies performed at our center from 8/1/2016 to 10/5/2020 as part of living donor liver evaluation. Donors underwent pre-donation protocol biopsy if any of the following were present: BMI≥28 kg/m^2, positive anti-nuclear or smooth muscle antibody, 1st degree relative of recipient with autoimmune liver disease (AILD) (PSC, PBC, AIH), heterozygote (Hz) for alpha-1-antitrypsin (A1AT) deficiency, steatosis on cross-sectional imaging, or at discretion of evaluating hepatologist. All donors who did not meet criteria for pre-donation biopsy underwent intraoperative biopsy at time of donation.

Results: A total of 70 pre-donation liver biopsies were performed (27% of donors evaluated during this time). The leading indication for biopsy was BMI>28 (43%), ANA (27%), 1st degree relative with AILD (17%), A1AT Hz (13%). A total of 19 patients (27%) had abnormal biopsies. Of these, 11 (16% of total donors biopsied) were excluded from donation based on biopsy results. Steatohepatitis was the most common histologic abnormality that precluded donation (5/11) followed by non-specific portal inflammation (3/11). Of 30 patients with a BMI>28, 6 had abnormal biopsies (including 4 who had steatohepatitis). Of 18 patients with positive ANA, only 3 had abnormal biopsies, all of whom had high titer ANA (≥1:160). Of 12 patients biopsied due to 1st degree relative with AILD (included 4 with positive ANA), all had normal biopsies. No patients that were A1AT heterozygotes (9) had abnormal biopsies (including PAS-D granules). No major complications of donor biopsies were reported. All intraoperative donor biopsies of individuals that did not meet criteria for pre-donation biopsy were normal.

Conclusions: Liver biopsy remains an important component of living liver donor evaluation, however, more focused patient selection criteria should be considered and ideally, be informed by additional multicenter studies.

Abstract# 1128

Update on Domino Liver Transplants - A Registry Report

R. Gruessner, J. Renz, A. Gruessner, *SUNY Downstate Medical Center, Brooklyn, NY*

Purpose: The ongoing shortage of livers in the setting of a growing waiting list remains a challenge in transplantation. First introduced in 1996, domino liver transplantation offers an option for patients with metabolic diseases to undergo a deceased donor liver transplant and utilize their native liver for a different patient with liver failure. Long-term analysis from a national US cohort is yet to be described.

Methods: Between 1996 to 2019, 210 domino liver transplants were reported to UNOS from 45 centers. Donor and recipient characteristics were analyzed. Overall

actuarial survival and liver graft failure were estimated using Kaplan-Meier. The 20-year study period was divided into 4 eras (1996-01, 2002-08, 2009-14, 2015-19) and overall and graft survival were compared using log-rank tests.

Results: Donor and recipient characteristics are summarized in Table 1. Most recipients (94%) underwent a primary transplant. The most common underlying disease in adult donors was amyloidosis (85%); in pediatric donors, maple syrup urine disease (84%). The most common reason for transplant in adult recipients was cirrhosis (69.3%), followed by liver malignancy (21.2%), and metabolic disease (2.2%). Of the adult recipients, 90% received the liver from an adult donor; in children, 45% of liver grafts came from adult donors. Overall survival and graft failure rates were similar between recipients and donors. Although there was a trend towards improved overall and graft survival in later years (2009-19), the differences were not statistically significant.

Conclusions: Domino liver transplants are a safe strategy for increasing availability of livers with patient and graft survival and graft rates comparable to deceased donor liver transplants.

Abstract# 1129

The Landscape of Non-Directed Living Liver Donation in the United States

L. R. Herbst, L. Zeiser, A. Massie, K. Herrick Reynolds, E. King, A. Gurakar, D. L. Segev, J. Garonzik Wang, A. M. Cameron, *Johns Hopkins University, Baltimore, MD*

Purpose: Non-directed donation (NDD) for kidney transplantation has increased substantially over the past decade, however the landscape of NDD for liver transplantation has yet not been described. Here, we quantify changes in liver NDD over time and characterize NDD liver donors and recipients.

Methods: We retrospectively analyzed SRTR data between 2000-2019 and compared 133 NDDs liver donors and recipients to 2725 directed living liver donors (DLD) and recipients.

Results: There were 133 liver NDD donors during our study period, increasing from 1% of all LDLTs in 2014 to 3% in 2017 and 2018, and then 10% of LDLTs in 2019 (Figure 1). Compared to DLDs, NDDs were younger (35 vs 40, p=0.002), more likely to be college educated (87.2% vs 76.5%, p=0.004), White (92.5% vs 77.8%, p<0.001), and have a lower BMI (24.9 vs 26.1, p=0.001) (Table 1). Compared to DLD recipients, recipients of NDDs were more often pediatric (39.1% vs 15.7% p<0.001) and had public insurance (51.1% vs. 32%, p<0.001). In comparison to DD recipients, more Black transplant candidates received an NDD liver (10.5% vs 4.1%, p=0.008) (Table 2).

Conclusions: NDD LDLT has increased substantially over time and pediatric patients are prioritized recipients. As liver NDD continues to expand, it is essential to understand historical trends to guide equitable allocation of NDD liver grafts.

Outcomes of Robotic Living Donor Right Hepatectomy in Liver Transplant Recipients: A Systematic Review and Meta-analysis

E. Lincango-Naranjo[1], E. Garces-Delgado[2], P. Solis-Pazmino[3], H. Alexander-Leon[4], G. Restrepo-Rodas[2], R. Mancero-Montalvo[2], C. J. Ponce[2], R. Cadena-Semanate[2], R. Vargas-Cordova[5], G. Herrera-Cevallos[6], A. Villarreal-Juris[7], S. Vallejo[1], C. Liu-Sanchez[8], L. P. Prokop[9], A. D. Guerron[10], O. J. Ponce[1], D. Moris[11], *[1]Knowledge and Evaluation Research Unit, Mayo Clinic, Rochester, MN, [2]Universidad Internacional del Ecuador, Quito, Ecuador, [3]Department of Otolaryngology-Head and Neck Surgery, Stanford University, Stanford, CA, [4]Universidad de las Americas, Quito, Ecuador, [5]Hospital General San Francisco IESS, Quito, Ecuador, [6]Hospital Metropolitano, Quito, Ecuador, [7]Universidad Central del Ecuador, Quito, Ecuador, [8]Universidad Peruana Cayetano Heredia, Lima, Peru, [9]Mayo Clinic Libraries, Mayo Clinic, Rochester, MN, [10]Department of Surgery, Duke University, Durham, NC, [11]Department of surgery, Duke University, Durham, NC*

Purpose: Living donor adult-to-adult liver transplantation (LT) has emerged as a feasible alternative to deceased donors. Advances in hepatobiliary surgery have allowed the introduction of robotic approaches to potentially decrease morbidity and mortality of recipient patients. Recent reports have evaluated the safety of robotic living donor right hepatectomy (RLDRH). We aimed to evaluate the outcomes of LT recipients after RLDRH compared to laparoscopic (LADRH) and open (ODRH) living donor right hepatectomy

Methods: A systematic search of several databases (e.g. MEDLINE) from inception to September 2020 was conducted. Experimental or observational comparative studies assessing the outcomes of LT recipients older than 18 years undergoing RLDRH versus ODRH or LADRH were included. CLARITY tool was used to assess the risk of bias of observational studies. Mean differences (MD) and relative risks (RR) and their 95% confidence interval (CI) were calculated with random-effects and restricted-maximum likelihood estimator for continuous and dichotomous outcomes

Results: Four studies were included. These studies had unclear risk of bias. A total of 151 LT recipients received liver after RLDRH (mean age=56.5 ±0.3), 118 after LADRH (mean age=53.8 ±11.2) and 248 after ODRH (mean age=55.3 ±6.7). The mean MELD score in RLDRH was higher than that of LADRH and ODRH (18.8 ±4.9; 16.2 ±8.3; 17.2 ±6.4). The indications for surgery reported in two studies were mostly hepatocellular carcinoma n=135 and end stage liver disease n=97, nonalcoholic steatohepatitis n=44. Only one study comparing RLDRH to LADRH found no differences in Clavien-Dindo complication (CD) I-II (RR: 1.00 95%CI 0.53, 1.87), III-IV (RR: 0.66 95%CI 0.39, 1.11) and mortality (RR: 2.27 95%CI 0.14-35.59). Likewise, four studies comparing RLDRH to ODRH found no difference in CD I-II (RR: 1.34 95%CI 0.71, 2.55), III-IV (RR: 0.71 95%CI 0.43, 1.16) and mortality risk (RR: 1.20 95%CI 0.55, 2.62)

Conclusions: RLDRH in recipient seems to be a safe approach with non-inferior outcomes compared to LADRH and ODRH. Experimental studies are needed to confirm this findings

Abstract# 1131

Is Low Systemic Fibrinolytic Activity During the Anhepatic Phase Liver Transplant Surgery Associate with the Dreaded Post-Operative Complication of Hepatic Artery Thrombosis?

H. B. Moore[1], Y. Bababekov[1], J. Pomposelli[1], T. Ferrell[1], F. Azam[1], M. Adams[2], D. Yoeli[1], R. Choudhury[1], M. Wachs[2], E. Pomfret[1], T. Nydam[1], *[1]University of Colorado, Aurora, CO, [2]Childrens Hospital Colorado, Aurora, CO*

Purpose: Removal of the native liver during transplantation results in impaired clearance of clot degrading proteins and activation of fibrinolysis as appreciated by Starzl in the 1960s. Hypofibrinolysis (lack of activation of the fibrinolytic system when anticipated) has been associated with thrombotic complications in non-transplant patients. Hypofibrinolysis in liver transplantation has not previously been evaluated, and would be presumed to increase the risk of hepatic artery thrombosis (HAT), particularly in living donor grafts or when arterial reconstruction is needed in cadaveric donors. We hypothesize that hypofibrinolysis during the anhepatic phase of surgery would be associated with an increased risk of HAT.

Methods: Consenting adult liver transplant recipients underwent a research thrombelastography (TEG) 15-minutes after portal vein ligation (anhepatic) to evaluate systemic fibrinolytic activity. Fibrinolysis activity was quantified by the amount of clot strength lost from peak clot strength in 30-minutes (LY30). A receiver operating characteristic curve (ROC) was used to identify a threshold for hepatic artery thrombosis (HAT) using the Youden index with the anheptic TEG LY30. Patient with the need for hepatic arterial reconstruction or received a living donor graft were classified as increased risk of thrombosis(IRT).

Results: 130 liver transplant patient recipients with a median laboratory na-MELD of 22 on the day of surgery were included in the analysis. IRT was present in 14%. HAT occurred in 5% of patients in which the rate was doubled in the IRT group (11%). The ROC Youden index identified a LY30 of <1% as a predictor of HAT (which defined hypofibrinolysis). Hypofibrinolysis was detected in 38% of patients. HAT occurred in 12% of patients with hypofibrinolysis vs 1.5% of patients that generated a fibrinolytic response (p=0.015). Patients with IRT and hypofibrinolysis had a 22% rate of HAT vs 0% in those that generated a fibrinolytic response (Figure). This same elevated HAT rate in hypofibrinolysis was also seen in patient with normal risk vascular anastomoses (10% hypo vs 1.5% Figure).

Conclusions: Hypofibrinolysis (anhepatic TEG LY30 < 1%) predicts increased risk of HAT. Attenuating HAT warrants further work to understand both mechanisms behind these findings and evaluating interventions, while avoiding excessive bleeding risk.

Abstract# 1132

Adult Deceased Donor Liver Transplantation with Split Liver Grafts vs Whole Liver Grafts. A Single-Center Experience

P. Vargas[1], C. Argo[2], H. Zachary[2], M. Stotts[2], N. Intagliata[2], P. Northup[2], S. Pelletier[1], J. Oberholzer[1], N. Goldaracena[1], *[1]Transplant Surgery, University of Virginia Health System, Charlottesville, VA, [2]Gastroenterology and Hepatology, University of Virginia Health System, Charlottesville, VA*

Purpose: The present study aims to report outcomes of adults following SLT in a single-center and compare this selected group with adults recipients following whole liver transplantation.

Methods: Between 2010 and 2019, SLT conducted at a single-center were identified retrospectively by electronic medical records review. A 1:1 case-control match was performed to match patients following split liver transplant and adult patients receiving a whole liver graft in the same period. The random match analysis was based on recipient age (±10 years), MELD (±5 points), and indication for transplant. Demographic variables, surgical variables, postoperative outcomes and long-term complications in the two groups of patients were compared.

Results: Twenty-one SLT were performed during the study period (SLT group) and 21 adults receiving a whole liver (WL group) were randomly generated. The median (IQR) age at transplant was 59 (49-63) for the SLT group and 59 (52-64) for the WL group (p=0.35). Recipient male gender proportion was higher, but not statistically different, in the WL group (52.4% vs 38.1% respectively;p=0.35). Recipient BMI (SLT=25.4 (23.8-28.2) vs WL=28 (23.8-32.7); p=0.11) and MELD (SLT= 23 (16-27) vs. WL= 25 (16.5-28); p=0.95) at transplant were similar between groups. The most common indication for liver transplant was Alcohol induced cirrhosis found in 7 (33.3%) recipients, followed by HCV cirrhosis in 4 (19%) and NASH in 3 (14.3%) recipients in both groups. Donor age (WL= 47 (33.5-66) vs. SLT= 16 (15-22) years, p=<0.001) and donor BMI (WL= 25.5 (21.3-31.2) vs SLT= 22.9 (20-24.7), p=<0.002) were significantly higher in the WL group compared to SLT group. Length of stay, ICU stay and readmission within 30 days post-transplant were similar between both groups. Re-transplantation occurred in one (4.8%) patient in

the SLT group. This consisted of a patient who received a right lobe split liver and subsequently developed HAT within the first 7 days after LT. No recipients in the WL group were re-transplanted. No mortality occurred in neither of the groups. Graft survival at 1-, 3- and 5- year were similar between groups (100% vs 95% for all time periods, p=0.31). Patient survival at 1-, 3- and 5- year were 100% in both groups.
Conclusions: SLT represents a feasible option to expand the donor pool with favorable outcomes in well-selected adult recipients.

Abstract# 1133

No Benefit of Antithymocyte Globulin in Living Donor Liver Transplant Recipients

N. Wilson, P. Nguyen, G. Saracino, R. Patel, G. Testa, T. Sam, *Baylor University Medical Center, Dallas, TX*
Purpose: Acute rejection after liver transplant is associated with increased risk of graft failure and mortality. Reports on rejection rates in living donor liver transplants (LDLT) rarely delineate patients who received rabbit antithymocyte globulin (rATG) as induction therapy. This study analyzes outcomes in LDLT recipients with regard to induction and maintenance immunosuppression received.
Methods: This single-center, retrospective cohort analysis included LDLT transplanted 01/2012 to 08/2020. Patients who died within 7 days or were re-transplanted within 30 days of LDLT were excluded. A protocol change in 2019 eliminated the use of rATG induction, delayed calcineurin inhibitor (CNI) initiation, and extended the corticosteroid taper for all liver transplant patients. All patients were started on mycophenolate mofetil 1000 mg twice daily or equivalent. Rejection was defined as biopsy-proven or clinically diagnosed based on lab values. Infection was assessed at 3 and 6 months by provider notes, medications, and lab results.
Results: Baseline characteristics and outcomes are shown in Table 1. rATG induction was given to 47 LDLT recipients, and 50 received no antibody induction. No significant differences in demographics were noted aside from a trend toward higher MELD-Na score in the rATG group. CNI initiation was significantly earlier in the rATG group. No significant differences were noted in rejection, graft survival, patient survival, renal function, infections, or readmissions between the two groups. Time to rejection, patient survival, and graft survival showed no differences.
Conclusions: In LDLT recipients, there was no noted benefit or harm in the use of rATG induction with regard to rejection, infection, renal function at 3 months, or 1 year patient or graft survival. Outcomes were overall similar compared with no antibody induction and empiric CNI delay to 1 to 3 days post-LDLT. No induction may be considered in living donor liver transplant and provides a cost savings opportunity.

	No rATG (N = 50)	rATG (N = 47)	P value

Abstract# LB 85

Comprehensive Intrahepatic Biliary Anatomy Underscores the Split-ability and the Origin of Biliary Leakage in Hemiliver Split Liver Transplant

J. Nguyen[1], K. Musto[1], M. Dougherty[1], R. Paz-Fugamalli[2], D. Harnois[1], *[1]Transplantation, Mayo Clinic Florida, Jacksonville, FL, [2]Radiology, Mayo Clinic Florida, Jacksonville, FL*
Purpose: Hemiliver splitting is an effective approach to optimize the number of liver allografts available for both adult and pediatric patients on liver transplant waitlist. The insidious and deadly complications of biliary leakage restrict a broader application of split liver transplantation (SLT). Here, we present a comprehensive analysis of intrahepatic biliary anatomy from a large cohort of deceased-donor whole liver transplants (DDLT) for split-ability and anatomic basis of biliary leakage in SLT.
Methods: We routinely perform post-transplant cholangiography in each DDLT. The cholangiographic images were reviewed for the 2511 DDLT from 1998 to 2012. The hepatic biliary anatomy was categorized I to IV according to the branching pattern and the number of right and left lobar hepatic duct (HD) at the liver hilum. The intrahepatic segmental bile ducts (SD) were classified as types I to IV with 0 to ≥2 SD crossing the virtual plane of hemiliver splitting.
Results: Among the 1572 DDLT that had analyzable cholangiograms, the biliary hilar anatomy included 24% of category I-A that is most optimal for splitting, 5% category I-B that has 2 HD for biliary reconstruction of the right hemilivers, 22% category I-C that is splitable but has ≥1 SD crossing the plane of parenchymal splitting potentially leading to bile leakage at the split surface, and 6% of category I-D that is not conducive for splitting. We identified the crossing of segment I bile duct into RHD, segments VII/VIII ducts into LHD, segment IV duct into RHD, and segment V duct into LHD as the potential origins for biliary leakage after SLT. The Table below summaries the 4 categories and 4 types of the hilar and segmental biliary patterns for the entire cohort.
Conclusions: In conclusion, the comprehensive assessment of intrahepatic biliary anatomy underscores ≥45% hemiliver split-ability, and accurately pinpoints the origins of bile leakage allowing for effective preemptive minimization of post-transplant biliary complications in SLT.

Hilar Biliary Category (n= 1572)		Intrahepatic biliary anatomy types			
		A (Splitable: single HD)	B (Marginal: 2 HD)	C (Marginal: ≤2 HD + 1 SD)	D (Not Splitable: (≥3 HD or ≥2 SD)
	I (n=890)	23.8% 	4.7% 	21.8% 	6.3% 	II (n=104)	0.0%	3.8%	0.3%	2.5%
	III (n=365)	0.0%	13.7%	0.8%	8.6%
	IV (n=213)	0.0%	4.6%	0.6%	8.3%

Abbreviations: HD, (lobar) hepatic duct at the hemiliver hilum; SD, segmental duct (duct from single segment).

Liver

Liver: MELD, Allocation and Donor Issues (DCD/ECD)

Abstract# 1134

Influence of Controlled Donation After Circulatory Death (cdcd) on Waiting List Mortalityfor Liver Transplantation in the Last 10 Years: The Spanish Experience

F. Alconchel, M. Royo-Villanova, J. Moya, L. Martínez-Alarcón, J. Zambudio, P. Cascales-Campos, T. Nicolás, R. Robles, F. Sánchez-Bueno, J. Pons, J. Rodríguez, A. Ríos, J. Fernández, P. Ramírez, *University Hospital Virgen Arrixaca (IMIB-Arrixaca), Murcia, Spain*
Purpose: Controlled donation after circulatory death (cDCD) provides one third of liver donors in Spain nowadays. The aim of our work is to evaluate the impact that cDCD has had on the evolution of mortality on the waiting list for liver transplant at our hospital over the last 10 years.
Methods: We retrospectively analyzed liver donation and transplant activity data at our center over the past 10 years through our records and those of the Spanish National Transplant Organization (ONT).
Results: Figure 1 shows the percentages of patients on the liver transplant waiting list who were transplanted, dropped-out from the list, or died on the list during the last 10 years (2010-2019). It should be noted that in the pre-cDCD era (before 2014) the mortality rate on the list was above 20%. However, in the age of controlled-DCD (from 2014 onwards) this percentage has decreased to 6% in 2019. As for the probability of liver transplantation per year (Figure 2), it has remained in progressive ascent despite the high rate of indication for liveer transplantation in our group (69.4 pmp, year 2018), the highest in Spain.The successful introduction of the controlled donation after circulatory death program at our hospital has reduced the mortality rate on the waiting list for liver transplants by 19% in 5 years. The probability of liver transplantation per year has increased by up to 20%.
Conclusions: Therefore, cDCD has allowed us to significantly reduce mortality on the waiting list for liver transplantation.

Figure1. Proportion of Patients on the waiting list for liver transplantation at our centre who have been transplanted, dropped out from the waiting list or have died while waiting for a liver transplant.

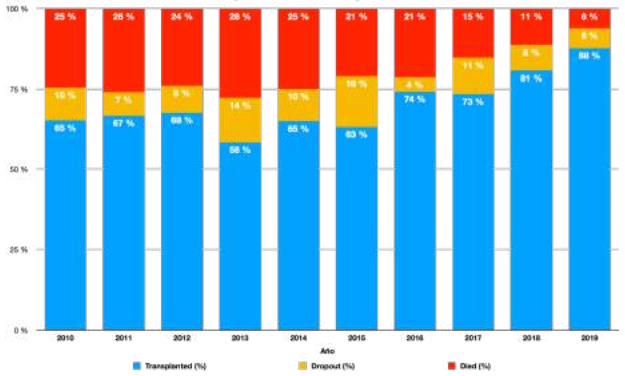

Figure 2. Total number of transplanted patients (blue), dropped from the waiting list (yellow) and deaths on the waiting list during each year. In green, the evolution of the probability of liver transplantation (%) in each year of the study is shown.

Abstract# 1135

Liver Simulated Allocation Model (LSAM) of a Height-Based Policy Change to Improve Sex Disparity in Liver Transplantation (LT)

S. Bernards[1], E. Lee[1], N. Leung[2], H. Zhao[2], M. Akan[3], M. Sarkar[1], S. Tayur[3], N. Mehta[1], *[1]UCSF, SF, CA, [2]City U, HK, Hong Kong, [3]CMU, Pittsburgh, PA*

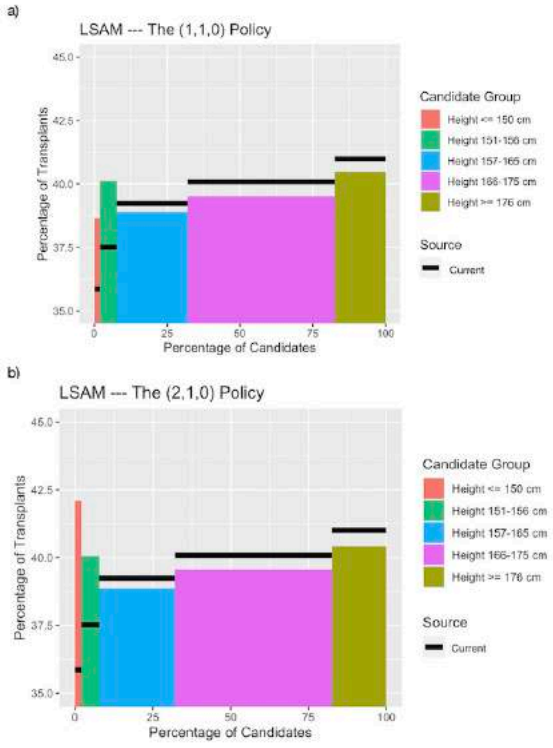
Purpose: Since the introduction of the MELD-based allocation system, women are now 30% less likely than men to undergo LT and have 20% higher waitlist mortality. These disparities are largely due to height differences in men and women though no national policies have been proposed to reduce sex disparities.

Methods: Patients were identified using the Scientific Registry of Transplant Recipients (SRTR) from 2014-2019. Patients were categorized into five groups by first dividing into thirds by height then dividing the shortest third into three groups to capture more granular differences in the most disadvantaged patients (<166 cm). We then used LSAM to model waitlist outcomes in five versions of awarding additional MELD points based on height categories compared to current policy. These scenarios award varying points to the three shortest height cohorts. For example, scenario "2,1,0" awards two additional points to the ≤150cm cohort, one to the 151-156cm cohort, and zero to the 157-165cm cohort.

Results: Patients (n=75,501) had a mean age of 55 years and median listing MELD of 15. Patients in the shortest categories were overwhelmingly female (96% of ≤150cm and 94% of 151-156cm versus 2.8% of ≥176cm). We re-demonstrated that shorter height is associated with decreased LT and increased risk of death without LT (for example, 24.5% dropout for ≤150cm and 21.6% for 151-156cm vs. 16.4% for ≥176cm). Two LSAM scenarios, "1,1,0" and "2,1,0" resulted in the greatest improvement in LT and death percentage for the shortest candidates with the least negative impact on taller candidates (Table, Figure). The patients who benefitted most in these two scenarios were patients ≤150cm and 151-156cm. For example, in the "1,1,0" scenario, LT for patients ≤150cm increased from 35.9% to 38.7% and death decreased from 11% to 10.7% with minimal impact on patients ≥176cm whose LT percentage went from 41% to 40.5% and death from 8.4% to 8.5%.

LSAM outcomes after 10 replications of current policy and 3 replications of the proposed policies.							
				LSAM Outcomes (LT % / Death without LT %)			
Height Group (centi-meters)	Number of LT candidates (%) (n=75,501)	Current	(1,0,0)	(1,1,0)	(1,1,1)	(2,1,0)	(3,2,1)
≤ 150	1,537 (2.0%)	35.9/ 11.0	39.6/ 10.3	38.7/ 10.7	38.1/ 10.5	42.1/ 9.9	43.3/ 9.7
151 - 156	4,369 (5.8%)	37.5/ 9.7	37.0/ 9.7	40.1/ 9.3	39.4/ 9.4	40.1/ 9.3	42.0/ 9.0
157 - 165	18,588 (25%)	39.2/ 9.4	39.1/ 9.3	38.9/ 9.4	41.4/ 9.1	38.9/ 9.4	41.2/ 9.1
166 - 175	25,984 (34%)	40.1/ 8.7	39.7/ 8.7	39.5/ 8.7	38.7/ 8.9	39.5/ 8.7	38.4/ 8.9
≥ 176	25,023 (33%)	41.0/ 8.4	40.7/ 8.5	40.5/ 8.5	39.7/ 8.7	40.4/ 8.6	39.2/ 8.8

Figure: (a) Visual representation of change in LT percentage after awarding one additional point each to the ≤ 150cm and 151-156 cm cohorts OR (b) two additional points to the ≤ 150cm cohort and one to the 151-156 cm cohort.



Conclusions: Awarding an additional 1-2 MELD points to the shortest 8% of LT candidates would improve waitlist outcomes for women with minimal impact on men. This strategy should be considered in national policy allocation in an effort to address sex-based disparities in LT.

Abstract# 1136

Utilization of Pre-Procurement Donor Liver Biopsy in Donation-after-circulatory-Death Liver Transplantation

A. C. Bolognese[1], N. Neidlinger[1], C. Sparks[2], A. Schneider[2], A. M. D'Alessandro[1], D. P. Foley[1], *[1]Department of Surgery, Division of Transplantation, University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]UW Organ and Tissue Donation, Madison, WI*

Purpose: Careful selection of suitable DCD donor livers is critical to obtain optimal transplant outcomes. In order to identify potentially suitable livers prior to DCD recoveries, we perform routine pre-procurement image-guided percutaneous liver biopsies with surrogate consent on potential DCD liver donors, with the exception of young donors with BMI < 25 kg/m^2 and without risk factors for or signs of liver disease. The purpose of this study was to examine the impact of pre-procurement liver biopsy on utilization of livers from DCD donors.

Methods: We retrospectively reviewed demographics, liver histology, and liver disposition of DCD donors who underwent pre-procurement liver biopsy from January 2000 through December 2019.

Results: Over a 20-year period, 219 DCD donors underwent pre-procurement liver biopsy. Twenty-eight (12.8%) donors were ruled out for liver donation based on biopsy findings, while 191 (87.2%) were deemed suitable for liver recovery and transplant. Of those donors ruled out for transplant based on histology, 11 (39.3%) were under 50 years old, and 10 (35.7%) had BMI < 30 kg/m^2; four (14.3%) were under 50 years old with a BMI < 30 kg/m^2. Of those with acceptable biopsies, 66 (34.6%) were over 50 years old and 16 (8.4%) were over 60 years old. Seventy-two (37.7%) donors with acceptable biopsies had a BMI > 30 kg/m^2, while 32 (16.8%) had a BMI > 35 kg/m^2. Twenty-seven (14.1%) donors with acceptable biopsies were both over the age of 50 and had BMI > 30 kg/m^2. No donors were lost due to complications from biopsy. Of the 191 livers with acceptable biopsies, 146 were successfully transplanted, 28 were deemed not suitable for transplant after recovery or intraoperative evaluation, and 17 were not recovered due to prolonged warm ischemia time or inability to allocate prior to recovery.

Conclusions: Pre-procurement liver biopsy ruled out 12.8% of DCD donor livers for transplant prior to recovery, and facilitated the successful recovery and transplant of two-thirds of potential DCD donor livers. Over half of livers ruled out by biopsy were from donors under age 50 and/or with BMI < 30 kg/m^2, while the majority of those donors with acceptable biopsies were 50 years or older and/or obese. Pre-procurement biopsy is a useful technique for evaluating potential DCD liver donors, allowing the surgeon to rule out unsuitable donors prior to deploying resources, and to identify usable livers that might otherwise be ruled out for transplant based on donor age or BMI. Consideration of liver biopsy in this group benefits organ procurement organizations and transplant centers by maximizing organ utilization and optimizing resource deployment.

Abstract# 1137

A Comparison Between Combined Liver Kidney Transplants to Liver Transplants Alone: A Systematic Review and Meta-analysis

S. Bouari[1], E. A. Rijkse[1], H. J. Metselaar[2], M. W. van den Hoogen[3], J. N. Ijzermans[1], J. de Jonge[1], W. G. Polak[1], R. C. Minnee[1], *[1]Surgery, Division of HPB & Transplant Surgery, Erasmus MC, Rotterdam, Netherlands, [2]Gastroenterology and Hepatology, Erasmus MC, Rotterdam, Netherlands, [3]Internal Medicine, Section of Nephrology and Transplantation, Erasmus MC, Rotterdam, Netherlands*

Purpose: Since the introduction of the Model for End-stage Liver disease (MELD) criteria in 2002, more combined liver kidney transplants are performed. Until 2017, no standard allocation policy for CLKT (Combined Liver Kidney Transplant) was available and each transplant center decided eligibility on a case-by-case basis for CLKT or Liver Transplant Alone (LTA). The aim of this systematic review was to compare the clinical outcomes of CLKT and LTA in patients with and without renal dysfunction.

Methods: We compared patient and graft survival in CLKT and LTA by conducting a systematic literature review from January 2000 through July 2020. To provide equal comparisons, we stratified our analyses into two groups according to whether renal dysfunction was also present in the LTA recipients.

Results: In total eleven studies were included in this review. Three studies compared CLKT to LTA in the presence of renal dysfunction and showed no significant difference in mortality risk at 1, 3 and 5 years (RR 1.03 [CI 0.97-1.09]; RR 1.06 [CI 0.99-1.13]; RR 1.08 [CI 0.98-1.19] respectively). Two studies compared CLKT to LTA in risk of liver graft loss at 1 and 3 years with a significant difference in favor of CLKT at 3 years (RR 1.10 [CI 0.93-1.30]; RR 1.15 [CI 1.08-1.24] respectively). Seven studies compared CLKT to LTA without renal dysfunction, showing no significant difference in mortality risk or risk of graft loss.

Conclusions: In conclusion, CLKT seems to be an appropriate therapeutic option for patients with both end stage liver and renal dysfunction. However, more data is necessary which KDIGO stage of renal dysfunction benefit the most from CLKT.

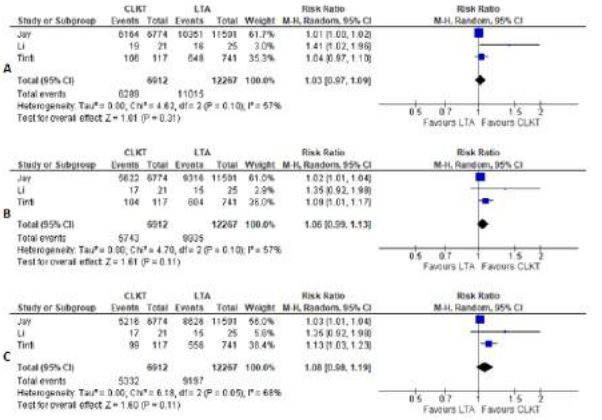

Figure 1: CLKT compared to LTA in patients with renal dysfunction. A: 1 year mortality risk. B: 3 year mortality risk. C: 5 year mortality risk.

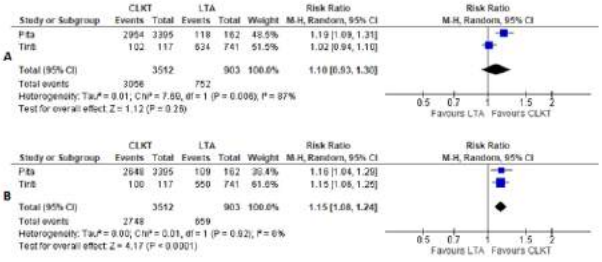

Figure 2: CLKT compared to LTA with renal dysfunction. A: 1 year risk of graft loss. B: 3 year risk of graft loss.

Abstract# 1138

Center Cost is Not a Barrier to Aggressive Utilization of DCD Livers

L. M. Brewer, D. M. Faulkner, A. J. Logan, J. M. Sneddon, G. N. Brock, N. Singh, W. K. Washburn, A. D. Schenk, *The Ohio State University Wexner Medical Center, Columbus, OH*

Purpose: Only 7% of livers transplanted in 2018 were from deceased from cardiac death (DCD) donors and only a minority of transplant centers aggressively utilize DCD donors. Not every attempted DCD procurement results in a transplant and costs associated with nonproductive DCD procurements are often viewed as a disincentive to aggressive DCD utilization. We examine productive DCD procurement rate from a purely financial perspective.

Methods: We reviewed all DCD liver offers received in one year at The Ohio State University Wexner Medical Center beginning February 2019. We analyzed offer characteristics and collected cost and reimbursement data associated with procurement attempts and completed transplants. We then modelled the rate of productive DCD procurements required to maintain net financial neutrality.

Results: 431 DCD liver offers were received. 57 offers (13.2%) were pursued and 36 successful transplants were performed (63% of total pursued). Pursued donors were located an average of 86 miles from our center (min 8, max 417). 47 organs were pursued using ground transportation and 10 utilizing air travel. For livers transplanted the average donor age was 36 and average BMI was 28. 48% of utilized donors were PHS increased risk and 14% were HepC NAT (+). Transplant recipients had a median MELD of 27 and 16% had HCC. Total reimbursements covered total procurement costs and with our 63% conversion rate a net positive margin was maintained.

Conclusions: Aggressive pursuit of livers from DCD donors allowed for a 35% expansion of our transplant volume. Our productive DCD conversion rate was 63%. 36 additional lives were saved using DCD livers without adverse financial impact on our transplant center.

Abstract# 1139

Post-Transplant Outcomes Comparing A2 Incompatible to Compatible Deceased Donor Liver Transplant Recipients

T. Chiang, M. A. Eagleson, S. Bae, J. Garonzik-Wang, D. Segev, A. B. Massie, *Department of Surgery, Johns Hopkins University School of Medicine, Baltimore, MD*

Purpose: Transplantation of A2 livers into type O and B recipients (A2i DDLT) is a growing modality to increase access to DDLT for O and B candidates. Most studies on the safety of A2i DDLT in conjunction with their induction agents have been single-center. We sought to explore A2i DDLT outcomes on a national scale.

Methods: Using SRTR data 1/2005-9/2020, we compared acute rejection and graft and patient survival in 763 A2i recipients vs 48,445 ABO-compatible (A2c) recipients using inverse probability of treatment weights to adjust for recipient confounders (demographics, BMI, cause of ESLD, MELD, calendar year). We compared outcomes stratified by induction agent (steroid only, thymoglobulin, basiliximab, others or multiple) among A2i.

Results: The number of A2i DDLT per year increased from 6 in 2000 to 82 in 2019 (Figure 1). A2i recipients spent less time on waitlist (A2i median (IQR) 60 (8-286) days vs A2c 89 (16-288) days, p<0.001) and had higher MELD at allocation (26 (15-34) vs. 20 (13-29), p<0.001). A2i recipients had longer length of stay after DDLT (12 (7-18)d vs 9 (7-16)d, p<0.001). Risk of acute rejection prior to discharge was higher among A2i (9.1% vs. 5.1%, weighted odds ratio (wOR)=$_{1.46}1.96_{2.64}$, p<0.001), but was otherwise comparable between the two groups at 6-months (9.4% vs. 8.7%, wOR=$_{0.88}1.19_{1.61}$, p=0.3), 1-year (12.3% vs. 11.6%, wOR=$_{0.87}1.14_{1.49}$, p=0.3), 2-year (14.7% vs. 13.6%, wOR=$_{0.91}1.17_{1.50}$, p=0.2) follow-up. Post-DDLT patient survival (wHR=$_{0.79}0.95_{1.13}$, p=0.5) and graft survival (wHR=$_{0.84}0.99_{1.17}$, p=0.9) were also comparable between groups (Figure 2). 16.1% and 11.7% of A2i received basiliximab and thymoglobulin as induction, respectively. There was no evidence of improved acute rejection or patient/graft survival for patients who received non-steroid induction agents.

Conclusions: Utilization of A2i DDLT has increased substantially over time. Transplant candidates who accepted A2i DDLT had shorter time to transplant, and generally comparable outcomes with A2c recipients. Our data support the continued practice of A2i DDLT to increase access to DDLT for type O and B candidates.

Abstract# 1140

Clinical Analysis of the Prognosis After Receiving a Liver Graft That Abandoned Transplantation Due to Poor Graft Conditions in the Centers Allocated as a Priority

H. Choi[1], G. Na[2], *[1]Surgery, Seoul St. Mary's hospital, The Catholic University of Korea, Seoul, Korea, Republic of, [2]Surgery, Bucheon St. Mary's hospital, The Catholic University of Korea, Bucheon, Korea, Republic of*

Purpose: LT has the limitation of lack of donors compared to those waiting for a transplant. Depending on the recipient's condition, even liver grafts with poor conditions may need to be transplanted. This study was conducted to analyze the prognosis after liver transplantation that abandoned transplantation due to poor graft conditions at the preceding centers.

Methods: From January 2010 to September 2020, Deceased-donor liver transplantation (DDLT) was performed in 160 patients in our center. Among them, 121 patients (allocated group) were preferentially allocated to our center by KONOS and the remaining 39 patients (24.4%, abandoned group) received liver grafts that were abandoned by other transplant centers due to poor organ conditions. To compare and analyze the clinical prognosis of the allocated group and the abandoned group, various perioperative factors and postoperative outcomes were evaluated.

Results: The average ages of the allocated and abandoned groups were 52.8 and 51.3 years, respectively (p=0.38). The preoperative Model for End-stage Liver Disease (MELD) score was 27.0 ± 10.4 in the allocation group and 27.0 ±11.8 in the abandoned group (p=0.99). There was no difference between the two groups in operation time (p=0.06) and intraoperative PRC transfusion (p=0.90). There was no difference between the two groups in hospital stay (p=0.26). The period of admission to the ICU after DDLT was 12.4 days in the abandoned group, which was longer than 8.7 days in the allocated group (p=0.04). In-hospital mortality occurred in 15 patients in the allocated group, and 5 patients in the abandoned group, so there was no difference between the two groups (p=0.47). The 5-year survival rate was 73.8% in the allocated group and 72.2% in the abandoned group, with no difference between the two groups (p=0.67)

Conclusions: Even if the graft that was abandoned due to poor condition, good results can be obtained if the transplant is carried out according to the recipient state. And as a result, it is expected that the discarded graft can be reduced.

Abstract# 1141

Allocation Changes and Covid Effect on Waiting Time for Liver Transplantation

L. Dageforde[1], Q. Yuan[2], N. Elias[1], *[1]Division of Transplantation, Massachusetts General Hospital, Boston, MA, [2]Organ Transplant Institute, 8th Medical Center, Chinese PLA General Hospital, Beijing, China*

Purpose: On April 30, 2019 the National Liver Review Board (NLRB) was implemented and patients meeting criteria for hepatocellular carcinoma exception

points received a score of the median MELD at transplant minus 3 (MMAT-3). On February 4, 2020 liver allocation changed to concentric circles. Approximately one month later the COVID pandemic altered liver transplantation in many regions for a period of time. It is unknown what effect these policy changes had on the wait-list time of patients for liver transplant.

Methods: We conducted a retrospective cohort study based on data from the Organ Procurement and Transplantation Network from December 2017-June 2020. Mean waiting-time was calculated for the transplants performed each month. An interrupted time-series analysis was used to examine the trend of mean waiting-time for liver transplantation from December 2017 to April 2019 (Pre-NLRB), May 2019 to January 2020 (NLRB-Alone), and February 2020 to June 2020 (Post-Allocation + COVID).

Results: In the Pre-NLRB era, the mean waiting time for liver transplantation was 240 days. For the NLRB-Alone era the mean waiting time was 209 days, and in the Post-Allocation + COVID era, the mean waiting time was 201 days (Figure 1). However, on interrupted time-series analysis, there was a significant trend in the mean waiting-time for transplant over time. The trend of the mean waiting-time increased in the NLRB-Alone era compared to the Pre-NLRB era ($p<0.001$). There was a decrease in the trend of mean waiting-time in the Post-Allocation + COVID era ($p<0.0001$) (Figure 2).

Conclusions: The NLRB and allocation change for liver transplantation has impacted the waiting time. The trend of the waiting time increased after the NLRB and MMAT-3 policy was implemented. After the allocation change, the trend of the waiting time for liver transplant has had a decreasing trajectory. The allocation change coincided closely with the COVID pandemic, which may have temporarily impacted the waiting-time for transplantation. More data is needed about the long-term impact of allocation changes on wait-list time for liver transplantation.

Abstract# 1142

Short Waiting Time is Not Associated with Decrease in Disease-free Survival in Liver Transplant Recipients with HCC

J. Daum[1], N. Gupta[1], B. Aqel[2], L. Mi[3], J. Harbell[4], *[1]School of Medicine, Mayo Clinic Arizona, Phoenix, AZ, [2]Hepatology, Mayo Clinic Arizona, Phoenix, AZ, [3]Biostatistics, Mayo Clinic Arizona, Phoenix, AZ, [4]Transplant Surgery, Mayo Clinic Arizona, Phoenix, AZ*

Purpose: Studies have suggested that shorter waiting times (WT) for liver transplant (LT) in patients with hepatocellular carcinoma (HCC) may be associated with increased HCC recurrence and decreased disease-free survival. MELD exception points are granted after patients have waited 6 months to address disparity in access for LT candidates without HCC. In this study, we aim to assess the outcome of LT (overall and disease free survival) in HCC patients who were transplanted without the proposed 6-month delay.

Methods: Retrospective review was conducted on all patients who underwent LT for HCC at our institution from 2014 to 2019. Patients with incidentally diagnosed with HCC on explant, those with living donors, and second time transplant recipients were excluded. Data was collected on characteristics of recipients and donors, MELD at transplant, WT with HCC, locoregional therapies, and tumor characteristics. WT was determined by either time from listing to transplant or time from HCC diagnosis to transplant, whichever was shorter. Survival analyses were conducted using Cox regression models and Kaplan Meier curves.

Results: 153 patients underwent LT during the study period: 102 had <6 months WT and 51 >6 months WT. Median WT was 1.9 months (IQR 0.9-3.6) vs 9.1 months (IQR 6.6-16.2) in the two groups. Patients with shorter WT had a significantly lower median MELD at transplant (22) than those who waited longer (28) ($p<0.0001$). However, those transplanted with shorter WT were not more likely to receive a DCD vs DBD donor ($p=0.150$). The 1 year disease free survival for those with shorter WT was 88.2% vs 96.1% for longer WT ($p=0.143$). The HCC recurrence rate was 7.8% in both WT groups ($p=1.0$). WT did not impact disease-free survival (Figure 1). Those with high risk HCC, however, had decreased disease-free survival (HR 3.33 (CI 1.36, 8.18)) ($p=0.030$) compared to patients with low risk HCC. Interestingly, AFP level, tumor stage at diagnosis and pathologic stage on explant were not associated with disease-free survival ($p=0.359$, $p=0.329$ and $p=0.203$).

Conclusions: Shorter WT to transplant did not significantly impact disease-free survival in patients with HCC. Moreover, shorter WT did not influence whether the patient received a DBD or DCD donor. Using extended criteria donors, patients with HCC and favorable tumor response had similar disease free survival when compared to those transplanted with 6 month delay.

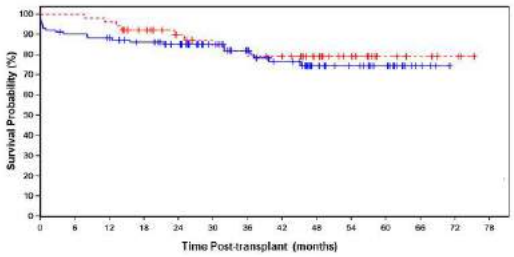

Figure 1: Disease-free Survival for HCC Transplant Recipients Waiting <6 months vs >6 months. Solid line indicates patients with waiting time < 6 months, dashed line indicates patients with > 6 months waiting time. For waiting time > 6 months, Adj HR 0.50 (95% CI 0.21-1.20). Logrank P-value 0.5233

Abstract# 1143

Time-averaged Oxygen Saturation During Donor Agonal Phase is Associated with Post-transplant Hepatic Graft Survival

K. C. Eddinger[1], E. M. Sonnenberg[1], A. Kayastha[2], N. Mahmud[3], D. E. Schaubel[2], P. L. Abt[1], *[1]Surgery, Hospital of the University of Pennsylvania, Philadelphia, PA, [2]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [3]Gastroenterology, Hospital of the University of Pennsylvania, Philadelphia, PA*

Purpose: Livers harvested from donors after cardiac death (DCD) are subjected to a period of relative warm ischemia during the agonal phase. There have been no large-scale studies correlating donor hemodynamics and oxygen saturation time-series data during the agonal phase with post-transplant graft outcomes.

Methods: UNOS data was utilized to identify DCD liver donors and their respective recipients. Donor and recipient demographic and clinical data, as well as recipient follow-up data were also available. Donor hemodynamic time-series data collected in the operating room during the agonal phase was provided by UNOS. The time-averaged agonal phase oxygen saturation was calculated by integrating the oxygen saturation curve between withdrawal and cross-clamp, and dividing by the length of this period. Cox regression was utilized to investigate the effects of time-averaged oxygen saturation on hepatic graft failure. Standard recipient and donor clinical and demographic characteristics were also included in the model.

Results: The hemodynamic profiles of 1967 DCD liver donors between 2013 and 2019 were analyzed. A mean of 11.5 data points were recorded for each patient during the agonal phase. Greater time-averaged oxygen saturation was found to be protective in terms of hepatic graft survival; each increase in average oxygen saturation by 5% was associated with a decrease in risk of graft failure by 3.3% ($p = 0.030$).

Conclusions: Agonal phase oxygen saturation profiles in DCD liver donors appear to be correlated with post-transplantation hepatic graft survival. Improved understanding of agonal phase hemodynamic changes and the effect on long-term graft outcomes may help to inform organ selection and expand the donor pool.

Abstract# 1144

Marginal Allografts in Liver Transplantation Have Very Limited Impact on Length of Stay

C. Goff[1], T. Zhang[1], M. McDonald[1], A. Anand[1], N. Galvan[2], F. Kanwal[3], G. Cholankeril[2], R. Hernaez[3], J. A. Goss[4], A. Rana[2], *[1]Department of Student Affairs, Baylor College of Medicine, Houston, TX, [2]Division of Abdominal Transplantation, Michael E DeBakey Department of General Surgery, Baylor College of Medicine, Houston, TX, [3]Division of Gastroenterology and Hepatology, Department of Medicine, Baylor College of Medicine, Houston, TX, [4]Liver Center, Division of Abdominal Transplantation, Department of General Surgery, Baylor College of Medicine, Houston, TX*

Purpose: The purpose of this study was to determine the effect on recipient length of hospital stay following transplantation with marginal allografts as specified by 6 different definitions.

Methods: 50,155 patients who received transplants from 2012 to 2020 were retrospectively analyzed through hospital discharge in this multi-center cohort study using the United Network for Organ Sharing database. Length of stay was defined as the time from transplant to discharge and was analyzed using Kaplan-Meier survival curves and multivariable Cox regression. Six different definitions were used to classify an allograft as being "marginal": 90th percentile Donor Risk Index allografts, Donation after Cardiac Death donors, national share donors, donors over 70, donors with >30% macrovesicular steatosis, or 90th percentile Discard Risk Index donors. Standard criteria donors were defined as not meeting any of these definitions.

Results: Of the 50,155 patients who received liver transplantation from 2012-2020, 24% (n=12,124) received organs that were classified as marginal. Recipients of marginal allografts had significantly lower laboratory Model for End-stage Liver Disease (MELD) scores with an average of 19.9 compared to 23.3 for recipients of standard allografts ($p < 0.001$). The use of allografts from Donation after Cardiac Death donors, national share donors, 90th percentile Donor Risk Index donors, 90th percentile Discard Risk Index donors, and donors older than 70 did not lead to a prolonged length of stay. However, the use of fatty liver allografts (macrovesicular steatosis >30%) was associated with a prolonged length of stay (hazard ratio, 0.93 [95% CI, 0.87 - 0.99]) (hazard ratio > 1 associated with earlier discharge). Cold ischemia time was associated with a shortened length of stay when less than 6 hours (hazard ratio, 1.09 [95% CI, 1.07 - 1.11]) and increased length of stay when greater than 12 hours (hazard ratio, 0.82 [95% CI, 0.76 - 0.89]).

Conclusions: Liver transplant centers can be more aggressive in their use of extended criteria donors with limited fear of increasing length of stay and its associated healthcare costs.

Abstract# 1145

Outcomes of DCD Allografts in Liver Transplant Recipients with HCC

N. Gupta[1], J. Daum[1], B. Aqel[2], L. Mi[3], J. Harbell[4], *[1]School of Medicine, Mayo Clinic Arizona, Phoenix, AZ, [2]Hepatology, Mayo Clinic Arizona, Phoenix, AZ, [3]Biostatistics, Mayo Clinic Arizona, Phoenix, AZ, [4]Transplant Surgery, Mayo Clinic Arizona, Phoenix, AZ*

Purpose: Early studies demonstrated inferior survival for liver transplant (LT) recipients with hepatocellular carcinoma (HCC) who received allografts from donation after cardiac death (DCD) donors vs donation after brain death (DBD) donors. DCD livers have been proposed as a way to decrease waiting time to transplantation. However, prior studies demonstrated increased risk of recurrence with shorter waiting times. The purpose of this study was to examine the impact of using DCD grafts on transplant waiting time, and graft and patient survival for recipients with HCC when compared to DBD recipients.

Methods: Retrospective review was conducted on all patients who underwent LT for HCC at our institution from 2014 to 2019. Exclusion criteria were: living donor transplants, re-transplants, and incidental HCC diagnosis on explant. Data was collected on recipient and donor demographics, transplant and donor characteristics, tumor characteristics, and patient and graft outcomes. Survival analyses were conducted on HCC recurrence, graft failure, and death using Cox regression models and Kaplan Meier curves.

Results: 153 patients underwent LT: 53 received a DCD organ and 100 received a DBD organ. The median transplant MELD for DCD recipients was 24.0, and for DBD recipients was 25.0 (p=0.99). 66% of DCD recipients received exception points, while 58% DBD recipients had exception points (p=0.39). There was no significant difference in AFP or tumor stage at diagnosis for DCD vs DBD recipients. The mean time from listing to transplant for DCD recipients was 7.2 months vs 5.8 months for DBD recipients (p=0.02). The HCC recurrence rate in DCD recipients was 5.7% vs 9.0% in DBD recipients (p=0.54). Multivariate analysis did not show a difference in overall (HR 1.40 (CI 0.52, 3.79) p=0.506) or disease free survival (HR 1.72 (CI 0.74, 4.00) p=0.207) for patients who received exception points. Overall and disease free survival was similar for patients who received DCD vs DBD allografts (Figure 1).

Conclusions: Overall patient survival and disease free survival was not affected by the use of DCD grafts. MELD exception at time of transplant was not associated with a higher likelihood of receiving a DBD graft. Transplant waiting time was longer in recipients of DCD grafts, though overall transplant waiting time and MELD score at transplant were low, reflecting the aggressive donor selection approach at our institution.

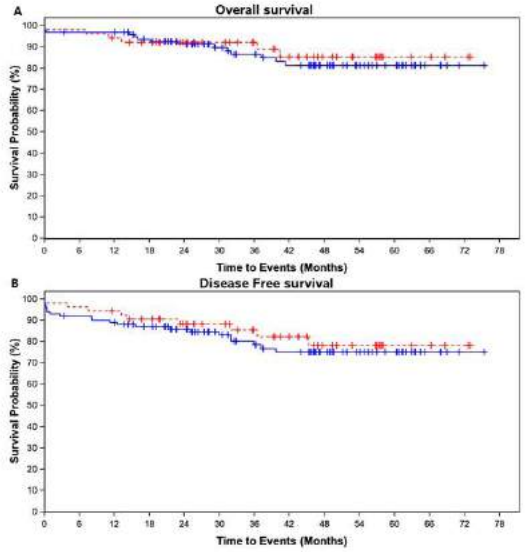

Figure 1. Survival Analysis for HCC Patients Receiving DCD vs DBD Liver Allografts
A) Overall survival for DCD (dashed line) vs DBD (solid line). HR 0.70 (95% CI 0.26-1.87). Logrank p = 0.66. B) Disease free survival for DCD (dashed line) vs DBD (solid line). HR 0.77 (95% CI 0.35-1.69). Logrank p = 0.54

Abstract# 1146

Geographic Divergence in Waitlist Registration and Trends in Waitlist Removal for Liver Transplantation in Patients with Nonalcoholic Steatohepatitis (NASH)

C. Hanlon[1], B. Saberi[2], L. Yuan[1], *[1]Internal Medicine - Transplant Hepatology, University of Southern California, Los Angeles, CA, [2]Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Boston, MA*

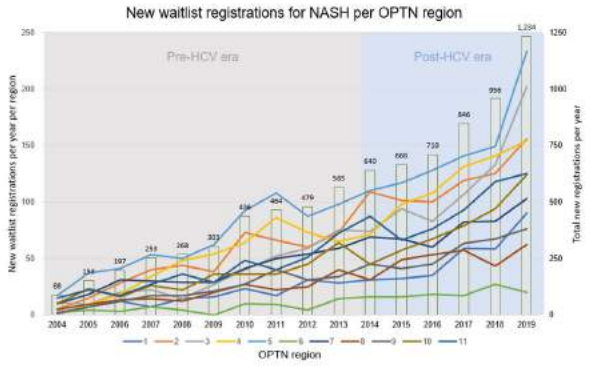
Purpose: This study aims to evaluate regional trends of waitlist (WL) registrations and removal for liver transplantation (LT) among United States (US) adults listed for nonalcoholic steatohepatitis (NASH).

Methods: We evaluated annual WL data for new transplant registrations listed for NASH in the US between January 1, 2004, and December 31, 2019 using deidentified data from the United Network for Organ Sharing (UNOS) LT database. Regional data was stratified as established by the Organ Procurement and Transplantation Network (OPTN).

Results: Between 2004-2019, a total of 9,030 new WL registrations were listed for NASH, 53.6% (4,842) of which were registered between 2014 and 2019. New WL registration for NASH increased consistently over time, from 83 new WL registrations for NASH in 2004 to 1345 in 2019. A total of 8,415 registrations were removed from the WL during the study period. The most common reasons for WL removal were death (29.69%), deterioration of condition (26.69%), or improvement

of condition (7.30%). Of patients who died before receiving LT, the most common causes of death were multiorgan failure (29.09%), sepsis (9.84%), or cardiovascular-related issues (8.76%).

Conclusions: There has been a substantial increase in new WL registrations for patients with NASH since 2004 throughout all OPTN regions. Total number of NASH patients awaiting LT has more than doubled and new WL registration for NASH has increased precipitously since 2014, potentially due to increasing diagnostic awareness of NASH and the introduction of highly effective antiviral therapy for HCV. These trends are likely to diminish in the future as HCV infection nears eradication. Over 50% of NASH WL registrations were removed due to death or clinical deterioration. Among this group, common causes of death were multiorgan failure, sepsis, or cardiovascular comorbidity. Future efforts must identify ways to meet this increasing demand for NASH-related LT while more effectively identifying high-risk NASH patients awaiting LT to improve WL mortality.



Characteristics of Patients Removed from Waitlist		
Reason for waitlist removal	**# of patients**	**Percent**
Died	2498	29.69
Condition deteriorated	2246	26.69
Condition improved	614	7.30
Transferred to another center	205	2.44
Refused transplant	138	1.64
Unable to contact candidate	94	1.12
Removed in error	11	0.13
Other	2609	31.00
Total	8415	100

Cause of Death of Patients Awaiting Transplant		
Cause of Death	**# of Patients**	**Percent**
Multi-organ failure	727	29.09
Sepsis	246	9.84
Cardiovascular	219	8.76
Hemorrhage	119	4.76
Pulmonary	114	4.56
Other infection	111	4.44
Cerebrovascular	54	2.16
Spontaneous bacterial peritonitis	21	0.84
Renal	20	0.80
Malignancy	15	0.60
Other	853	34.13
Total	2499	100

Abstract# 1147

Waitlist Outcomes for Exception Candidates Following the Implementation of MMaT/250 Score

T. Ishaque[1], J. G. Wang[1], S. Karhadkar[2], D. Segev[1], A. B. Massie[1], *[1]Johns Hopkins Medical Institutions, Baltimore, MD, [2]Temple University, Philadelphia, PA*

Purpose: Starting in May 2019, exception points were allocated based on DSA-level median-MELD-at-transplant (MMaT/DSA). In February 2020, the exception point system was further modified based on MMaT within 250 nautical miles (MMaT/250). Our aim was to describe subsequent changes in transplant and mortality rates for exception and non-exception candidates.

Methods: Using SRTR data on 26,992 adult, first-time, active, DDLT waitlist registrants, we compared DDLT rates in non-HCC exception vs. HCC-exception vs. non-exception candidates using Cox regression in three eras: Pre-MMat (02/01/2018-01/31/2019), MMaT/DSA (05/01/2019-02/03/2020), and MMaT/250 (02/04/2020-08/30/2020). In addition, we compared waitlist mortality/dropout risk among non-HCC exception, HCC-exception, non-exception candidates of the same allocation priority using Fine and Gray method after accounting for the competing risk of transplantation.

Results: During pre-MMat era, Non-HCC exception candidates had 15% (aHR= $_{0.75}$ 0.85 $_{0.96}$) lower access to DDLT compared to non-exception candidates; similar DDLT rate in MMaT/DSA-era (aHR= $_{0.86}$ 1.04 $_{1.24}$) and then attenuated to 38% lower access to DDLT in MMaT/250 era (aHR=$_{0.48}$ 0.62 $_{0.80}$) (Figure 1). HCC-exception candidates had 52 % (aHR=$_{0.44}$ 0.48 $_{0.53}$), 69% (aHR=$_{0.27}$ 0.31 $_{0.35}$) and 79% (aHR=$_{0.17}$ 0.21 $_{0.25}$) lower access to DDLT compared to non-exception candidates during pre-MMat , MMaT/DSA and MMaT/250 era , respectively. Non-HCC exception and non-exception candidates with the same allocation MELD had comparable risk of death/dropout during pre-MMaT and MMaT/DSA eras (Figure 2). However, under MMaT/250, non-HCC exception patients had twice as much risk of death/dropout compared to non-exception patients (asHR= $_{1.06}$ 2.08 $_{4.06}$); risk was potentially elevated for HCC exception patients although not statistically significant (asHR = $_{0.93}$ 1.67 $_{3.01}$) (Figure 2).

Conclusions: Following the implementation of MMaT/250 score, access to DDLT was attenuated for both Non-HCC exception and HCC exception candidates. In addition, the policy change appeared to have substantially increased risk of death/dropout for non-HCC exception candidates compared to non-exception candidates. The COVID-19 pandemic may have influenced death/dropout in the MMaT/250 era.

LIVER

Abstract# 1148

Extreme Hyponatremia as a Risk Factor for Early Mortality After Liver Transplantation in the MELD-Sodium Era

T. Ivanics[1], S. Leonard-Murali[1], H. Mouzaihem[1], D. Moonka[2], T. Kitajima[1], S. Yeddula[1], T. Shamaa[1], M. Rizzari[1], K. Collins[1], A. Yoshida[1], M. Abouljoud[1], S. Nagai[1], *[1]Division of Transplant and Hepatobiliary Surgery, Henry Ford Hospital, Detroit, MI, [2]Division of Gastroenterology and Hepatology, Henry Ford Hospital, Detroit, MI*

Purpose: The impact of hyponatremia on waitlist and post-transplant outcomes following the implementation of MELD-Na based liver allocation remains unclear. We sought to evaluate waitlist and post-liver transplant (LT) outcomes in patients with hyponatremia before and after implementation of MELD-Na based allocation.

Methods: Adult primary LT candidates between 2009 and 2019 were identified in the OPTN/UNOS database. Multi-organ transplants and re-LT were excluded. Two eras were defined: before and after implementation of MELD-Na based allocation. Patients were categorized into the following groups: extreme hyponatremia (≤120 mEq/L), severe hyponatremia (121-124), moderate hyponatremia (125-129), mild hyponatremia (130-134), normal sodium (135-145), and hypernatremia (>145). 90-day waitlist outcomes and post-LT survival were compared according to era and sodium concentration using Fine-Gray and Cox proportional hazard models.

Results: 87,845 patients were included in waitlist outcome analyses (N=64,911[pre-MELD-Na], N=22,934[post-MELD-Na]). In the pre-MELD-Na era, extreme hyponatremia at listing was associated with increased risk of 90-day waitlist mortality (HR:2.08,p<0.001) and lower likelihood of transplant within 90-days (HR:0.63,p<0.001). In the post-MELD-Na era, patients with extreme hyponatremia had a similar risk of waitlist mortality (HR:1.02,p=0.95) and likelihood of transplant (HR:0.90,p=0.48) as patients with normal serum sodium. Post-LT outcome analyses included 30,639 and 12,585 patients in pre and post-MELD-Na eras. While extreme hyponatremia was not associated with post-LT mortality in the pre-MELD-Na era, it was an independent risk factor for 90-day post-LT mortality in the post-MELD-Na era. (HR:5.20,p<0.001).

Conclusions: With the introduction of MELD-Na based allocation, waitlist outcomes have improved in patients with extreme hyponatremia but paradoxically been associated with worse short-term post-LT survival.

Abstract# 1149

Long-term Outcomes of Donation After Cardiac Death and Living Donor Liver Transplant for Primary Sclerosing Cholangitis: An Analysis of UNOS Registry from 2002-2020

T. Kitajima, S. Nagai, T. Ivanics, T. Shamaa, K. Collins, M. Rizzari, A. Yoshida, M. Abouljoud, D. Moonka, *Transplant and Hepatobiliary Surgery, Henry Ford Hospital, Detroit, MI*

Purpose: Use of donation after circulatory death (DCD) grafts is a reported risk factor for worse outcomes after liver transplant (LT) for primary sclerosing cholangitis (PSC) due to increased biliary complications. However, outcomes comparing DCD, donation after brain death (DBD) donors, and living donor LT (LDLT) have not been fully studied in a recent cohort. This study aims to assess outcomes of LT for PSC with each graft type.

Methods: Using OPTN/UNOS data, we analyzed LT patients with PSC or primary biliary cholangitis (PBC) between 2002 and 2020. Patients with status 1A, multi-organ or re-transplant were excluded. One, 5, and 10-year graft survival (GS) were compared between PSC and PBC groups. Next, outcomes were compared between DBD-LT, DCD-LT, and LDLT in each group. In PSC, the three types of donor grafts were compared for cause of graft loss. Finally, transplant outcomes were analyzed in early era (2002-2010) and late era (2011-2020). Risks were adjusted by recipient variables.

Results: 3,946 PSC and 2,675 PBC patients were eligible. Among PSC patients, 3,099 (78.5%), 151 (3.8%), and 696 (17.7%) received DBD-LT, DCD-LT and LDLT. One, 5, and 10-year GS were similar between PSC and PBC. In PSC, DCD-LT had significantly higher risk of 1, 5, and 10-year graft loss than DBD-LT (1-year: HR 1.87, p=0.007, 5-year: HR 1.74, p=0.001, 10-year: HR 1.60, p=0.003) whereas LDLT had similar risks of 5 and 10-year graft loss. In contrast, outcomes were comparable between donor types in PBC. As a cause of graft loss in PSC, DCD-LT had a significantly higher incidence of biliary complications and PSC recurrence than other graft types (**Table**). In DCD of PSC, the risk of 5-year recurrence was relatively higher in early era than in late era. 16.5% of DCD-LT lost grafts because of PSC recurrence or biliary issues vs 4.5% in DBD-LT and 5.1% in LDLT. Incidence of re-transplant was highest in DCD-LT (DCD-LT 18.5% vs DBD-LT 10.2% vs LDLT 10.6%, p=0.005). This finding was more prominent in early era whereas the risk of 3 and 5-year graft loss was similar among all graft types in late era (**Figure**).

Conclusions: In PSC patients, the outcomes of the use of DCD grafts has improved over time although it was associated with worse post-transplant outcomes because of relatively higher recurrence and biliary complications in the earlier era. This finding was not seen in PBC. LDLT had similar outcomes to DBD-LT. The use of DCD grafts is an option for PSC with appropriate donor selection.

Table. Incidence of graft loss according to the causes in PSC patients

		DBD	DCD	LDLT	p
1-year	Biliary complications*	19 (0.6)	5 (3.3)	5 (0.7)	0.003
	Diffuse cholangiopathy**	0	2 (1.3)	3 (0.4)	<0.001
	Recurrent PSC	4 (0.1)	2 (1.3)	0	0.001
5-year	Biliary complications*	35 (1.1)	11 (7.3)	8 (1.1)	<0.001

Abstract# 1150

Pre-transplant Prognostic Nutritional Index Predicts Short-term Outcomes After Liver Transplantation

E. Lisznyai, T. Kitajima, K. Delvecchio, A. Mohamed, S. Yeddula, T. Shamaa, T. Ivanics, K. Collins, M. Rizzari, A. Yoshida, M. Abouljoud, S. Nagai, *Transplant Institute, Henry Ford Hospital, Detroit, MI*

Purpose: To understand the importance of pre-transplant nutritional status in optimizing liver transplant outcomes.

Methods: The prognostic nutritional index (PNI) is a serum marker of nutrition and inflammation. We hypothesized pre-transplant PNI would predict short-term post-LT outcomes in deceased donor liver transplant (DDLT) patients. 451 patients underwent primary DDLT between 2013-2018 at our center. Re-transplants, multi-organ transplants and living donor liver transplants were excluded. Pre-transplant PNI = (10)*[albumin (g/dL)] + (0.005)*[Total Lymphocyte Count (/μL)]. PNI was analyzed as both a continuous and categorical variable. ROC curves yielded an optimal PNI cutoff of 35 to compare short-term outcomes between PNI≥35 and PNI<35 cohorts. Risk factors for patient death within 1-year were analyzed using Cox regression models and adjusted by recipient factors at LT.

Results: Multivariable analysis associated PNI with 1-year survival as a continuous variable (HR=0.94, 95% CI=0.90-0.98; p=0.007). Of 451 patients, 215 (47.7%) had PNI<35. MELD score at time of transplant was higher in PNI<35 (22 vs. 19; p=0.028). Recipient age, gender, BMI, donor age, rates of diabetes mellitus and donors after cardiac death were equivocal. PNI<35 demonstrated lower 1-year survival (89.6% vs. 95.2%; p=0.026, **Figure A**). After risk adjustment, PNI<35 showed higher risk of 6-month (HR=2.44; p=0.047) and 1-year death (HR=2.47; p=0.018). Multivariable analysis revealed PNI<35 at LT (HR=2.37; p=0.023) was an independent risk factor for patient death within 1 year (**Figure B**).

Conclusions: Lower pre-transplant PNI portended worse short-term survival in DDLT patients. PNI may be useful in evaluating pre-transplant nutritional status and optimizing LT outcomes.

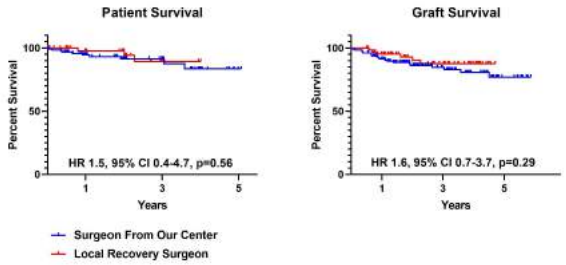
Abstract# 1151

Role of Recovering Surgeon in DCD Liver Transplant Outcomes

E. Macdonough, K. Pont, B. Aqel, K. Valenti, W. Hewitt, A. Moss, K. S. Reddy, C. Jadlowiec, *Mayo Clinic, Phoenix, AZ*

Purpose: Donation after cardiac death (DCD) liver transplant (LT) outcomes have continued to improve. Variability in outcomes has been attributed to center and recovering surgeon experience. The aim of this study was to assess DCD LT outcomes utilizing surgeons from a large volume DCD center versus local recovering surgeons.
Methods: We assessed 196 DCD LT at our center spanning the years of 2015 to 2020. Multivisceral DCD transplants were excluded.
Results: During this period, there were 129 DCD LT recovered utilizing a surgeon from our center (65.8%) and 67 procured by a local recovery surgeon (34.2%). There were no differences in recipient age (p=0.43) or Model for End Liver Disease (MELD, 20.9±6.0 vs. 20.6±6.2, p=0.77). There likewise were no differences in donor age (p=0.12) and warm ischemia time (WIT) (21.6±6.7 vs. 21.7±4.8, p=0.86). Cold ischemia time was longer for livers recovered utilizing local recovery surgeons (6.4±1.3 vs. 5.2±0.9, p<0.0001). There were no differences in early allograft dysfunction (EAD) (Bili ≥10, p=0.28; INR ≥1.6 p=0.70, AST>2000, p=0.33), primary nonfunction rates (0.8% vs. 0.0%, p=0.47) and ischemic cholangiopathy (IC) treated with endoscopy alone (17.1% vs. 11.9%, p=0.35). In total, all-cause IC at any timepoint, including >1 year, requiring re-transplantation was 7.1%. For IC in the absence of hepatic artery (HA) issues, re-transplant rates in the first year were 0.8% for grafts recovered by our center versus 3.0% for those procured by local recovering surgeons (p=0.23). For all-cause IC, including grafts with HA issues, re-LT rates were 3.9% for grafts recovered by our center and 3.0% for those procured by local surgeons (p=0.75). There were no differences in patient (HR 1.5, 95% CI 0.4-4.7, p=0.56) or graft (HR 1.6, 95% CI 0.7-3.7, p=0.29) survival. One-year graft survival for livers recovered by our center was 91.5% compared to 95.5% for grafts with local recovery.
Conclusions: Excellent DCD LT outcomes can be achieved with the utilization of local recovery surgeons as long as WIT is minimized. Center experience with managing DCD grafts plays a more significant role compared to the role of the recovering surgeon in DCD outcomes. There may be an opportunity to increase utilization of DCD livers by expanding usage of local recovery surgeons.



Post-Transplant Outcomes			
	Recovery Surgeon From Our Center n=129	**Local Recovery Surgeon** n=67	***P* value**
Hospital LOS, median (days)	6.0	6.0	0.71

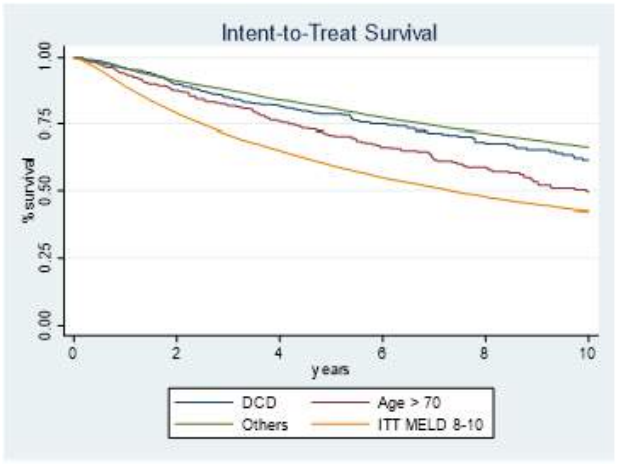
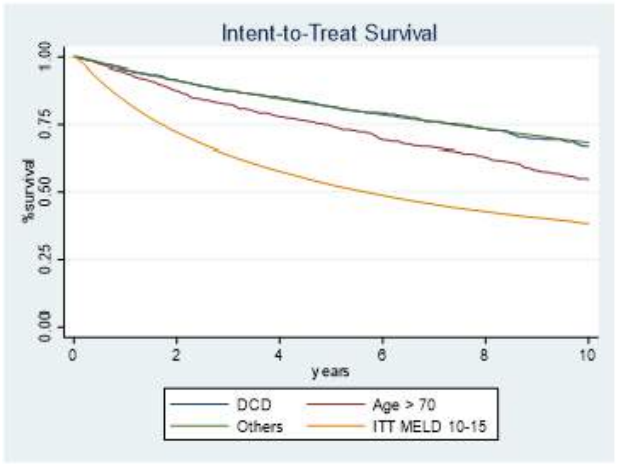
Abstract# 1152

The Survival Benefits of Using Marginal Allografts in Liver Transplantation

T. H. Malik[1], E. L. Godfrey[1], A. Rana[2], *[1]Baylor College of Medicine, Houston, TX, [2]Department of Abdominal Transplantation, Baylor College of Medicine, Houston, TX*

Purpose: Our study assessed whether using marginal allografts at initial time of listing provided similar or greater survival benefit versus waiting on the transplant waitlist for a "non-marginal" allograft.
Methods: We used the United Network for Organ Sharing (UNOS) database to retrospectively analyze 156,646 liver transplant recipients, excluding patients cross-listed for other transplants. We stratified the patients into three ranges based on their MELD scores: 8-10 (n = 33,891), 10-15 (n = 74,191), 15-18 (n = 48,564). Within each MELD range, patients were divided into four groups. Within a range, the first three groups were patients who were transplanted with an allograft from 1) a donation after circulatory death, 2) a donor between 70-100 years of age, or 3) all other allografts not in the first two categories. The fourth category is distinct from the first three as these are patients who were listed with an initial MELD score within the MELD range but were not transplanted within that MELD range. Within each MELD range, we performed a Kaplan-Meier time-to-event survival analysis with death as our primary outcome. Statistical significance was determined using log-rank testing (Stata Corp).
Results: Figure 1 contains our survival curves for each MELD range, and table 1 provides agranular view of 10-year survival values for the four categories within each MELD range. Furthermore, Table 1 displays statistically significant differences as calculated using the log-rank test for equality of survival functions within each MELD range. Across all three MELD ranges, all four survival curves differed from every other survival curve ($p < 0.05$) aside from DCD vs. all other allograft donations. Notably, across all three MELD ranges, patients who remained on the waitlist with a given MELD score had worse 10-year survival vs. all three other categories of patients who received DCD, donors > 70, or other allografts at that same MELD score.
Conclusions: In patients with MELD scores as low as 8, this analysis demonstrates that there is significant benefit gained by using marginal allografts in patients who would otherwise remain on the waitlist as their condition deteriorates until a non-marginal allograft is procured.





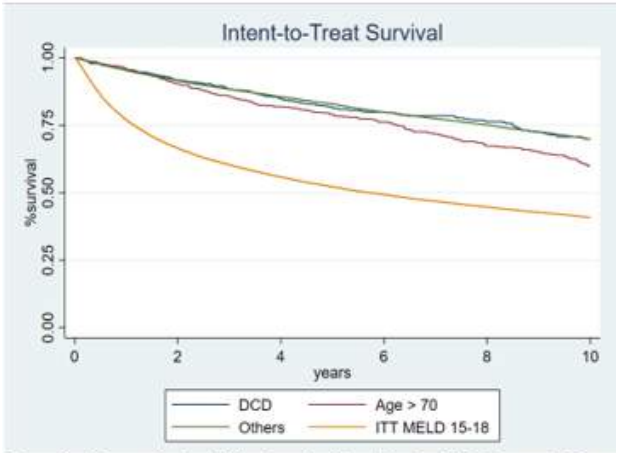


Figure 1: 10-year Kaplan-Meier Survival Analysis for MELD Scores: 8-10

Table 1: 10-year Kaplan-Meier Liver Transplant Survival

MELD Score		Type of Allograft	10-year Survival (%, 95% Confidence Interval)
8-10	MELD at Transplant	DCD[a]	61.6 (55.4 - 67.2)
		Donor Age >70 years[b]	49.6 (43.1 - 55.8)
		All other allografts[a]	66.6 (65.3 - 67.9)
	MELD at Listing[c]		42.5 (41.5 - 43.4)
10-15	MELD at Transplant	DCD[a]	66.8 (62.8 - 70.4)
		Donor Age >70 years[b]	54.8 (51.0 - 58.5)
		All other allografts[a]	68.2 (67.4 - 69.0)
	MELD at Listing[c]		38.1 (37.5 - 38.7)
15-18	MELD at Transplant	DCD[a]	69.9 (65.6 - 73.9)
		Donor Age >70 years[b]	59.8 (55.3 - 64.1)
		All other allografts[a]	69.8 (68.9 - 70.8)
	MELD at Listing[c]		40.9 (40.1 - 41.6)

Note: Within a MELD Score range, unique superscripts denote a statistically significant difference ($p < 0.05$)

Abstract# 1153

When One Size Does Not Fit All: Geographically Heterogeneous Liver Distribution

M. A. Mankowski[1], S. Gentry[2], D. Segev[3], N. Trichakis[4], *[1]KAUST, Thuwal, Saudi Arabia, [2]US Naval Academy, Annapolis, MD, [3]JHU, Baltimore, MD, [4]MIT, Boston, MA*

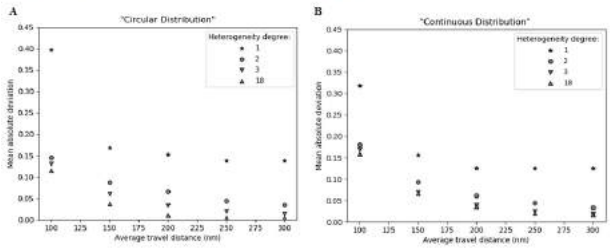
Purpose: The new liver allocation system prioritizes distribution within acuity circles, instead of within DSAs. Acuity circles have the same radius around all donor hospitals across the U.S. Allowing acuity circles around each hospital to have their own customized radii might reduce the geographic disparity in the liver supply/demand ratio.[SG1] We explored the effect of a heterogeneous system with an increasing number of alternative radii for acuity circles. Similarly, we explored the effect of continuous distribution policies with an increasing number of alternatives for the weight given to geographic.

Methods: Using 07/2013-06/2017 SRTR data, we compared circular (continuous) distribution schemes using a uniform radius (geographic distance weight) across the U.S., with schemes using an increasing number of alternatives for the radii (weights). We built an optimization model that designed distribution schemes that minimize the variation (mean absolute deviation) in the liver supply/demand ratio between transplant centers.

Results: For circular (continuous) distribution, when using two radii (distance weight) alternatives, instead of one, the variation in liver supply to demand ratio decreased from 0.153 (0.126) to 0.066 (0.061) having livers travel 200 nm on average (Fig. 1). Maintaining a similar level of variation in the liver supply/demand ratio, the average liver travel could be reduced from 200 nm to 150 nm when distributing organs using 18 different circle radii or distance weights instead of three (Fig.1). Donor hospitals in fairly isolated areas like California, Texas, Florida, or Washington were sharing livers locally to nearby transplant centers. On the contrary, many donor hospitals in the Midwest and Southeast could share organs broadly to boost transplant rates in distant undersupplied centers (Fig.2).

Conclusions: Geographically heterogeneous liver distribution schemes can reduce variation in the liver supply/demand ratio among transplant centers and reduce transportation burden. The latter potential diminishes fast with heterogeneity of the scheme.

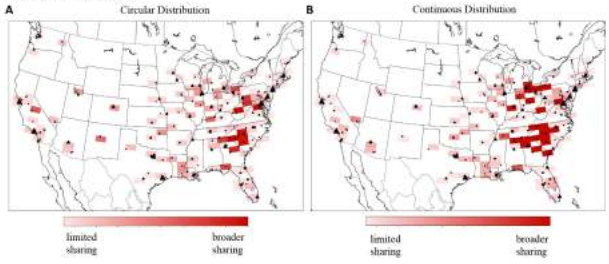
Figure 1. Mean absolute deviation (MAD)* of liver supply/demand ratio among transplant centers for "Circular Distribution" (A) and "ContinuousDistribution" (B) schemes with varying heterogeneity degree,** where livers traveled 100, 150, … , 300 nm on average.



* The Mean absolute deviation (MAD) describes the variation in liver supply/demand ratios among transplant centers.

** Heterogeneity degree is the number of different circle sizes or proximity score functions allowed in the policy to assign to all donor hospitals; for instance, the heterogeneity degree equal one denotes geographically homogenous distribution, while heterogeneity degree equal three indicated we used three different circle sizes or proximity score functions to vary sharing in different locations.

Figure 2. Heat maps show how broadly the livers are shared for the optimized "Circular Distribution" scheme (A) and the "Continuous Distribution" scheme (B) with heterogeneity degree* 18 where livers travel 200 nm on average. Data of 181 (10%) the largest donor hospitals, accounting for 50% liver supply.



* Heterogeneity degree is the number of different circle sizes or proximity score functions allowed in the policy to assign to all donor hospitals; for instance, the heterogeneity degree equal one denotes geographically homogenous distribution, while heterogeneity degree equal three indicated we used three different circle sizes or proximity score functions to vary sharing in different locations.

Abstract# 1154

Evaluation of Increasing Liver Discard Rate and Waiting List Drop-Off in Post-MELD Era

R. Matsumoto[1], K. Halazun[2], J. Emond[1], B. Samstein[2], R. S. Brown Jr.[2], L. Dove[1], T. Kato[1], *[1]Center for Liver Disease and Transplantation, Columbia University Irving Medical Center, New York, NY, [2]Center for Liver Disease and Transplantation, Weill Cornell Medical Center, New York, NY*

Purpose: As number of donors and transplant cases rises each year, it is important to evaluate not only post-transplant survival rate but also the organ utilization rate and the waiting-list mortality. In addition, it is known that current regulatory criteria could potentially encourage risk-averse behavior by transplant centers and could affect the organ utilization rate.

Methods: Adult post-liver transplant (LT) survivals, intention-to-treat (ITT) survivals, DRI (Donor Risk Index), waiting-list (WL) drop-off rates and organ discard rates were studied in the post-MELD era using the Scientific Registry Transplant Recipients (SRTR) database and Stata software. We divided the era in five different cohorts (C1: 2002-2006, C2: 2007-2009, C3: 2010-2012, C4: 2013-2015, C5: 2016-2018). We calculated the organ discard rate as total number of cases in which organs were not used for transplant divided by total number of cases that were authorized to donation. We also defined the incidence of waitlist removal due to death and condition deterioration as the WL drop-off rate.

Results: The discard rate was significantly higher in the most recent cohort compared to other cohorts ($p<0.05$) in spite of DRI being stable for the past 10 years. The number of discard organ (discard rate) was 6068 (24.88%), 6536 (24.9%) and 8028 (25.74%) in C3, C4 and C5, respectively. The mean DRI for entire donors was 1.360, 1.3631,1.367, whereas DRI for discarded organ was 1.439,1.441, 1.447 in C3, C4 and C5, respectively ($p>0.1$). From early to recent years, the LT survival has been significantly improving. The 1-year post-LT survival was 77.04%, 80.99%, 83.4%, 87.15%, 88.72% in C1, C2, C3, C4, and C5 respectively. However, there was a significant increase in WL drop-off rate in recent cohorts. (24.69 vs 29.5 vs 32.14 vs 32.69 vs 37.78 100 person-years.) Moreover, there was no significant improvement in ITT survival. One-year ITT survival was 70.29%, 70.30%, 68.15%, 69.52%, and 70.76% in C1, C2, C3, C4, and C5 respectively.

Conclusions: Although post-liver transplant survival rate has been improving significantly, WL drop-off rate has been increasing. In addition, despite the DRI for discarded organs being stable throughout the past 10 years, the discard rate has been rising. These outcomes may be the result of centers avoiding high-risk transplants aiming to increase the post-transplant survival. The effect of new liver allocation policy has yet to be determined.

Abstract# 1155

Survival Adult Liver Transplantation: Experience in a Latinoamerican High Complexity Center. 15 Years with More Than 500 Transplants

C. A. Murcia, N. Ramirez, M. E. Ramos, C. Benavides, J. Rivera, G. Mejia, *Transplant Unit, Fundación Cardioinfantil, Bogotá, Colombia*

Purpose: Liver disease is one of the main causes of chronic disease morbidity and mortality in the world and liver transplantation is the only curative intervention once patients reach the terminal stage. We describe the experience our center during 15 years of performing liver transplantation in adults. Our objective was to carry out a descriptive analysis of our population, as well as a survival analysis that allowed us to compare ourselves with international standards.

Methods: This is a retrospective report which includes a cohort of adult patients who went into liver transplantation from 2005 to July 2020 at the Fundacion Cardioinfantil. We performed a descriptive analysis evaluating patient survival using the Kaplan Meyer method.

Results: This study included 532 patients, 97% undergoing transplantation with a deceased donor and 3% with a living donor, 50.1% were women and the remaining were men. The mean age at the time of transplantation was 52.3 years. The main indication for transplantation was non-cholestatic cirrhosis, the majority of the patients had a MELD Score less than 15. 6% of the patients were transplanted in acute liver failure. Overall survival was 89.3%, 84.9%, 81.9%, at the 1st, 3rd and 5th year respectively.

Conclusions: Patients undergoing liver transplantation in our center have had satisfactory results comparable with international standards. This is explained by the multidisciplinary work, the experience acquired during more than 15 years, the development and update in surgical techniques, immunosuppression regimens, organ allocation, donor selection, optimization of pre-operative status, and postoperative surveillance.

Abstract# 1156

Early Effects of Acuity Circle-Based Liver Allocation During Covid-19 Pandemic in the United States

S. Nagai, T. Ivanics, T. Kitajima, M. Shamaa, M. Lu, S. Yeddula, K. Collins, M. Rizzari, A. Yoshida, M. Abouljoud, *Henry Ford Hospital, Detroit, MI*

Purpose: One month before the COVID-19 pandemic was declared, liver transplant (LT) allocation in the US was updated (February 4th, 2020), by introducing the acuity circle (AC)-based model. This study evaluated the early effects of the AC-based allocation on waitlist outcomes.

Methods: Adult candidates listed between January 1st, 2019, and June 30th, 2020, were evaluated. Two periods were defined according to the listing date (pre- and post-AC), and 90-day waitlist outcomes were compared. Data was censored if none of the events had occurred before the end of the period. The median transplant MELD score of each state was calculated, and states were defined as low-(<25th%ile), mid-(25th-75th%ile), and high-(>75th%ile) MELD regions. In addition, transplanted patients were categorized into 3 groups according to their final MELD score (6-14, 15-28, 29+). Organ sharing and donor characteristics were compared between eras.

Results: 12,546 and 3,932 candidates in pre and post-AC eras were eligible. The post-AC era was associated with significantly lower 90-day waitlist mortality (HR=0.75, 95%CI=0.62-0.90; p=0.002) and higher transplant probability (HR=1.19, 95%CI=1.10-1.29; p<0.001). When outcomes were assessed in each MELD region group, improvement in outcomes was significant in mid-MELD regions, but not in other MELD regions. Among 5,971 and 772 transplanted in the pre and post-AC eras, national sharing significantly increased in all groups (overall: 7.4% to 32.5%, P<0.001). In contrast, a significant increase and decrease in the proportion of donation-after-circulatory-death (DCD)-LT was observed in the low- and mid-MELD regions, respectively. Another subgroup analysis showed that national sharing significantly increased in those with a score of 15-28 (7.6% to 22.1%, P<0.001) and 29+ (5.0% to 39.6%, P<0.001), but not in those with score of 6-14 (15.7% to 22.7%, P=0.11). Patients with a MELD score 15-28 received DCD-LT more frequently in post-AC era, but not in those with a score of 29+. (**Table**).

Conclusions: Despite the COVID-19 pandemic, AC-based allocation improved waitlist outcomes in mid-MELD regions. While other regions had comparable out-

comes, aggressive utilization of DCD might offset possible negative effects of the AC-based model and/or pandemic in low-MELD regions. Organ acceptance practice may be significantly changed in certain regions/patient populations such as DCD acceptance for patients with mid MELD score in lower MELD regions. It is crucial to carefully monitor possible effects of those changes on post-transplant outcomes.

Proportion of DCD-LT in pre and post-AC eras			
	Pe-AC era	Post-AC era	P value
Overall	537/5971 (9.5%)	78/772 (10.3%)	0.48
Low-MELD regions	249/2034 (12.5%)	48/259 (18.8%)	0.006
Mid-MELD regions	222/2704 (8.8%)	18/343 (5.4%)	0.03
High-MELD regions	66/1233 (5.7%)	12/170 (7.2%)	0.45
Patients with MELD 6-14	55/389 (19.6%)	6/22 (35.3%)	0.121
Patients with MELD 15-28	318/2447 (13.9%)	56/267 (21.5%)	0.001
Patients with MELD 29+	74/2286 (3.3%)	11/462 (2.4%)	0.33

Abstract# 1157

Liver Transplant Outcomes Using Nationally Allocated Grafts

S. Ohara[1], B. Lizaola-Mayo[2], P. Morgan[2], D. Das[3], J. Wagler[4], K. S. Reddy[2], B. Aqel[2], A. Moss[2], C. Jadlowiec[2], *[1]Valleywise Health General Surgery Residency Program, Phoenix, AZ, [2]Mayo Clinic, Phoenix, AZ, [3]Mayo Clinic Alix School of Medicine, Scottsdale, AZ, [4]John C Lincoln, Phoenix, AZ*

Purpose: There is national variation in acceptance criteria and utilization of livers across transplant centers. Data pertaining to outcomes of liver grafts declined by local and regional centers that go on to be placed nationally remains limited.

Methods: We assessed 617 liver transplants (LT) at our center spanning the years of 2015 through June 2020. Multivisceral and living donor LT were excluded.

Results: During this period, 109 (17.7%) nationally allocated liver allografts were used compared to 508 (82.3%) from local and regional donors. Recipients of nationally allocated livers had lower Model for End Stage Liver Disease (MELD) scores (18.2± 7.1 vs. 22.8±8.6, p<0.0001). A higher percentage of nationally allocated livers came as post-cross clamp offers (29.4% vs. 13.4%, p<0.0001); 14.7% came from donation after cardiac death donors (p=0.18). Cold ischemia time (CIT) was higher for national offers (7.9±1.9 vs. 5.8±1.7, p<0.0001) and a local recovery surgeon was more often utilized (66.1% vs. 38.6%, p<0.0001). There were no differences in hospital length of stay (p=0.89). Early allograft dysfunction (AST>2000) was more common in nationally allocated grafts (p<0.0001) however there were no differences in the rate of primary nonfunction (1.8% vs. 0.6%, p=0.19). There were no differences in patient (HR 1.07, 95% CI 0.44-2.57, p=0.88) or graft (HR 0.78, 95% CI 0.48-1.28, p=0.35) survival.

Conclusions: Despite longer CIT and geographic challenges, outcomes from nationally allocated liver allografts are excellent and comparable to those seen from local and regional donors.

Post-Transplant Outcomes			
	National n=109	**Local-Regional** n=508	***P* value**

Abstract# 1158

Assessing Liver Transplant Outcomes Utilizing Post-Cross Clamp Offers

K. Pont[1], E. Macdonough[1], D. Das[2], K. Valenti[1], P. Morgan[1], B. Aqel[1], A. Mathur[1], A. Moss[1], K. S. Reddy[1], C. Jadlowiec[1], *[1]Mayo Clinic, Phoenix, AZ, [2]Mayo Clinic Alix School of Medicine, Scottsdale, AZ*

Purpose: With the ongoing organ shortage, there has been increased interest in utilizing post-cross clamp (XC) liver allografts as a means of expanding the donor pool. Limited data exists on the outcomes of these allografts.

Methods: We assessed 613 liver transplants (LT) at our center spanning the years of 2015 through June 2020. Multivisceral and living donor LT were excluded.

Results: During this period there were 101 post-XC LT (16.5%) and 512 standard XC LT (83.5%). There were no differences in recipient age (p=0.46) or sex (p=0.41). Model for End Stage Liver Disease (MELD) scores were lower for post-XC recipients (18.5±8.1 vs. 22.7±8.5, p<0.0001). Post-XC offers came from younger donors (p=0.002), were more likely to be from donation after brain death donors (93.1%, p<0.0001) and be regional (55.4%) or national (31.7%) offers (p<0.0001). Cold ischemia time (CIT) was higher for post-XC LT (p<0.0001). Post-XC grafts were more likely to have moderate-severe steatosis (15.8% vs. 8.8%, p=0.03). There were no differences in recipient hospital length of stay (p=0.71) or incidence early allograft dysfunction between the two groups (Bili ≥10, p=0.63; INR ≥1.6, p=0.32; AST >2000, p=0.35). For post-XC offers, 1-year patient survival was 95.0% versus 95.9% in standard XC offers (HR 0.67, 95% CI 0.29-1.54, p=0.28). One-year graft survival was 93.1% versus 93.2% (HR 1.13, 95% CI 0.59-2.14, p=0.72).

Conclusions: Outcomes utilizing post-XC liver allografts are good. Appropriate recipient selection, dedicated procurement coordinators and preparedness of the surgical teams with anticipation of longer CIT are important variables that allow for the successful utilization of post-XC liver offers.

Abstract# 1159

Impact of Liver Acuity Circles on Timing of Donor Procurements

R. Radhakrishnan, D. Goldberg, *University of Miami, Miami, FL*

Purpose: The Acuity Circles (AC) policy in liver transplantation led to broader organ sharing, whereby many organ procurement organization (OPOs) had to coordinate organ offers and donor procurement schedules with a greater number of transplant centers. These changes may have delayed the time from brain death to organ recovery in a variety of ways, including: increased number of possible 'local' recipients, logistics in working with new centers, and logistics of travel to for procuring teams from further away. We sought to evaluate the association between implementation of the AC policy and donor procurement timing (time from brain death declaration to cross clamp).
Methods: Retrospective study using Organ Procurement and Transplantation Network (OPTN)/United Network for Organ Sharing (UNOS) data. We included all brain-dead donors where the liver was transplant and procurement occurred in a donor service area (DSA) with a liver transplant centers. We divided the data into two periods: 8/8/2019-2/3/2020 (pre-AC) and 3/5/2020-8/31/2010 (post-AC), allowing for a 1-month run-in period for centers and OPOs to adjust to the AC policy. We fit multivariable mixed-effects linear regression models (primary outcome: time from brain death declaration to cross-clamp) adjusting for factors associated with donor organ acceptance that may increase time/logistics (e.g., donor age, concurrent thoracic organ placement), and viability (including donor age, BMI, and serum total bilirubin) and performed marginal standardization to calculate the OPO-level measures of time from brain death to cross-clamp pre- vs post-AC.
Results: In multivariable models, the difference in time from brain death-to-cross clamp time for liver donors increased by an average of more than 2 hours after implementation of AC (beta coefficient: 2.17, 95% CI: 1.37, 2.97; p<0.001). The magnitude of the difference in brain death to cross clamp time pre- vs. post-AC varied across OPOs, however the median time increased in every OPO when there was no current thoracic organ placement, and 55/56 OPOs when there was concurrent thoracic organ placement [Figure].
Conclusions: Implementation of the AC policy was associated with significantly increased donor delays, as measured by the timing from brain death declaration to cross clamp. Future research is needed to quantify whether these delays impacted graft outcome, OPO costs, ICU bed utilization, and family perspectives on the donation process.

Abstract# 1160

Patient Feedback of a Patient and Family Decision Support Tool for Liver Organ Offer Decisions

C. Schaffhausen[1], S. Chu[2], M. Bruin[3], S. Chinnakotla[3], J. Lake[3], A. Israni[4], *[1]Hennepin Healthcare Research Institute, Minneapolis, MN, [2]University of Minnesota (UMN), Minneapolis, MN, [3]UMN, Minneapolis, MN, [4]Hennepin Healthcare, UMN, Minneapolis, MN*

Purpose: For liver transplant candidates on the waiting list, deciding to accept a donor organ with known or potential risk factors can be stressful and can lead to declined offers. Current education for patients and family often takes place during transplant evaluations and can be overwhelming and result in low retention and poor understanding of donor quality. Prior feedback from surgeons and hepatologists (n=20) informed the initial content of a decision support tool for patients and family, including multiple topics to convey concepts about the donor pool, the donor match, the process for reviewing offers, and donor risks. We sought pilot evaluations from transplant coordinators and liver transplant candidates to improve usefulness and relevance.
Methods: Pilot interviews with liver transplant coordinators and candidates included discussions about current patient education and a review of mockups of a decision support tool. Questionnaires collected participant demographics. Mockups included a series of static images representing a website design to prepare patients and family for an organ offer decision. Initial images describe general topics [Figure 1], followed by specific donor types and risks. Interviews were conducted remotely via video streaming, and audio was recorded. Qualitative feedback on graphics, text, and navigation was summarized to inform future development of an interactive tool.
Results: 4 transplant coordinators and 9 transplant candidates participated in pilot interviews for the current development phase. Each interview lasted approximately 1 hour. Feedback on the graphic style was positive and reinforced the benefit of a patient-friendly aesthetic. Participants considered the content an appropriate overview of the donor offer process. Participants had varying views of the offer process prior to reviewing the tool, but consistently reported the review was beneficial. A preferred dissemination strategy was to share with patients after an evaluation as a review when MELD scores suggest an offer is feasible. Mockups were iteratively refined based on feedback.
Conclusions: New decision support tools for offer decisions may address gaps in patient counseling, in particular after evaluations. Stakeholder feedback supports ongoing development of an interactive tool to help patients and family prepare for an offer decision.

Table 1: Patient excerpts from pilot interviews

Prior to review of decision support tool	During or after review of decision support tool
"My understanding is my coordinator will call and tell me that they have a liver waiting for me or they have a match ready, and that's really all I know about that."	"Yeah, that is the big one. You want to have [the review] done ahead of time."
"I would say I would be readily accepting of [an offer] because like I said, I would be pretty sick by the time I got a dead donor."	"I like it. It's well laid out. I really like the illustrations."
"I haven't learned about any kind of risk factors, as far as how it would relate individually to me."	"The writing is simple enough, it's not too packed with information, it's just the basics and it's brief enough, but it covers all the information."
"One thing that never occurred to me is the possibility of informed that there's a liver available and then being told ... that there might be some risk... And then I would have to decide whether or not to accept, whether the benefits outweigh the risk. And the idea of having to make that decision had never crossed my mind until just now."	"I'm terrible in the moment asking questions... because my brain kind of freezes up. And so this is good, I like this [practice offer] concept a lot."
"I feel a lot of mixed feelings about it, which translate into, for me stress and anxiety."	"I wish I had been told a lot of this because like a lot of my family had questions similar to this for me and I'm just like, 'I don't know; all I know is that we're banking on a living donor and if that doesn't work out then I'm not really sure.'"
	"And for me, I think it's helpful to have it driven home that before an offer is even made, your doctor has looked at this and thinks it's a good idea for you--because I personally put a lot of faith in my doctor"
	"The feeling I get from these pages is that if you need one and you're offered one, you better take it, because you might not get offered again."
	"It has decreased my anxiety and just kind of organized things in my brain, I guess, more."

Figure 1: Example mockup page of decision support tool showing an overview of the donor pool.

Abstract# 1161

Liver Transplantation with Super Obese Donors (BMI≥50) Grafts: An Acceptable Pathway to Expand the Donor Pool. Analysis of the OPTN/UNOS Liver Transplant Registry

P. Vargas[1], C. Argo[2], H. Zachary[2], M. Stotts[2], N. Intagliata[2], P. Northup[2], J. Oberholzer[1], S. Pelletier[1], N. Goldaracena[1], *[1]Transplant Surgery, University of Virginia Health System, Charlottesville, VA, [2]Gastroenterology and Hepatology, University of Virginia Health System, Charlottesville, VA*

Purpose: We aimed to analyze the impact of donor body mass index (BMI) on recipient morbidity and survival following liver transplantation (LT).
Methods: The UNOS-STAR database was queried to identify adult patients undergoing LT from 2010-2019. Records of recipients and donors <18 years, donors with BMI <18, transplants before 2010, split-LT, living donors LT, DCD and multi-organ transplants were excluded from the analysis. Graft outcomes were analyzed by univariate analyses. Graft and patient survival were assessed by Kaplan-Meier curves.
Results: 45,721 patients were identified. Of these, 45,300 patients received a graft from a donor with BMI<50 (BMI<50 group) and 421 from a super obese donor (BMI≥50 group). Recipients median (IQR) age (57 (51-63) vs 58 (52-64), p=0.11) and BMI (28.1 (24.6-32.4) vs 29 (25.5-33.3), p=0.43) were similar in the donor BMI<50 group vs donor BMI≥50 group, respectively. Proportion of males among groups were significantly higher in the donor BMI≥50 group (79.1% vs 67.4%, p=<0.001). Donor mean age was significantly higher in the donor BMI≥50 group

(47 (38-55) vs 44 (30-56), p=<0.001). By definition donor BMI was significantly higher in the donor BMI≥50 group (54.1 (51.7-57.6) vs 27.1 (23.8-31.4), p=<0.001). Proportion of donor males were significantly higher in the BMI<50 group (59.0% vs 24.9%, p=0.001). The percentage of liver biopsy performed was significantly higher in the BMI≥50 group (83.4% vs 41.5%, p=<0.001). Among those with liver biopsy, the median (IQR) of reported percentage of macrosteatosis was 10% (4-20) in the donor BMI≥50 group vs 5% (0-10) in the donor BMI <50 group, p=<0.001). Macrosteatosis ≥30% was present in 56/339 (16%) in the donor BMI≥50 group vs 1626/17940 (8.6%) in the donor BMI<50 group, p=<0.001. Mean CIT was similar between groups. Median length of stay after LT was significantly longer in the donor BMI<50 group (10 (0-737) vs 9 (0-126) days, p=<0.001). Graft failure, recipient death and re-transplant rates were similar between groups (5.7%, 16.9% and 2.5% for the donor BMI<50 group and 5.7%, 14.7% and 2.6% in the donor BMI≥50 group, respectively, p=0.61). Graft and patient survival at 1-, 3- and 5- year were similar between groups (89%, 79%, 73% vs 88%, 81%, 71%, p=0.83, and 91%, 81%, 75% vs 91%, 83%, 71%, p=0.87, in the donor BMI <50 group vs donor BMI≥50 group, respectively).

Conclusions: The use of grafts from super obese donors can safely expand the organ pool in selected recipients. Grafts from super obese donors should not be rule out based solely on their BMI and biopsy of these grafts might play an important role in the decision-making process.

Abstract# LB 86

Assessing the Impact of the New Liver Allocation Policy on Transplant Center and Organ Procurement Organization Logistics

W. P. Sawyer[1], A. Gracon[2], *[1]General Surgery, Ochsner Health System, New Orleans, LA, [2]Transplant Surgery, Ochsner Health System, New Orleans, LA*

Purpose: In February 2020, a new policy for liver allocation was instituted in an effort to reduce geographic disparity in median MELD at transplant. To accomplish this, the use of geographic prioritization based on Organ Procurement and Transplantation Network (OPTN) donor service areas (DSAs) and regions was abandoned in favor of prioritization incorporating acuity circles around the donor hospital. Modelling for acuity circle-based allocation prior to policy implementation demonstrated a significant increase in travel time and travel distance, which may affect the cost of procurement and organ cold ischemia time. The purpose of this study was to assess this impact at our OPO and transplant center.

Methods: A retrospective analysis was performed that included all liver procurements managed by the Louisiana Organ Procurement Association (LOPA) and all liver transplant recipients at Ochsner Health between 1 January 2019 to 12 December 2020. A comparison of logistical considerations pre- and post-policy implementation were evaluated. Differences were determined using Welch t-test in R with a 95% confidence level as the cutoff.

Results: For the study period, a total of 246 livers were allocated by the OPO prior to the change in allocation policy compared to 188 livers after. Based on donor service area, the percentage of livers allocated to local recipients pre-policy change was 73% compared to 51% post-policy (p<0.001). The mean transport distance for livers allocated by the OPO pre-policy was 195 miles compared to 213 miles post-policy (p=0.45). At Ochsner Health, for the same period, 221 liver transplants were performed pre-policy and 148 liver transplants post-policy. Based on donor service area, 53% of recipients received a local donor pre-policy compared to 46% post-policy (p=0.17). The mean transport distance pre-policy was 260 miles compared to 273 miles post-policy (p=0.67). Finally, the mean cold ischemia time for the donor liver was 310 minutes pre-policy compared to 305 minutes post-policy (p=0.49).

Conclusions: Even with modeling to suggest a significant increase in transport distance as a result of the new liver allocation policy, our data suggest that did not occur for our transplant center or for livers allocated to other centers by our OPO. This is despite a significant reduction in the percentage of organs allocated to local recipients. Similarly, we did not observe a change in cold ischemia time for livers transplanted at our center. It is likely that the effect of this policy on transport distance will be highly variable based on transplant center location and the geographic distribution of other centers in proximity. As a result, the burden of increased transport time, increased transport cost, as well as the possibility of increased cold ischemia time will impact transplant centers differently.

Abstract# LB 87

Improved Patient Survival in DCD Liver Transplantation

O. Bushara[1], J. Alhalel[1], H. Azad[1], T. Cerri[2], S. Zafer[2], J. C. Caicedo[1], *[1]Department of Surgery, Division of Organ Transplantation, Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Rosalind Franklin Medical School, Chicago, IL*

Purpose: We aim to investigate longitudinal outcomes in DCD liver transplantation over a 10-year period and elucidate trends in patient survival, biliary complication rates, and complication severity.

Methods: Our cohort included DCD liver transplantations from 2006 to 2016. Donors that were not type III DCD and re-transplantations were excluded. We collected data on patient and donor characteristics, complication rates and severity up to 1 year post-transplant, and 1- and 5- year patient survival. Patients were separated into high and low complication groups based on comprehensive complication index (CCI), with a high level of complication defined as a CCI above 26.2. Linear and logistic regression and Fisher's exact test were used when appropriate.

Results: Of 1046 liver transplantations conducted between 2006-2016 at our institution, 96 (9.2%) were first time transplantations using type III DCD organs. Transplantation volume trended upwards over time. Donor and recipient characteristics including MELD score did not differ over time. One-year survival trended upwards (p=0.16) and five-year survival significantly improved over time (p=0.04). Complication severity (p=0.21) and biliary complication rates (p=0.45) did not differ over the time period and had no clear trend. (Figure 1) A total of 29 (30.2%) patients had biliary complications following discharge, including 17 (17.7%) patients with ischemic cholangiopathy. Three (3.1%) patients required re-transplantation, with 2 (2.1%) due to ischemic cholangiopathy. The 1- (89.6% vs. 91.0%, p=0.86) and 5-year patient survival (62.1% vs. 73.1%, p=0.28) did not differ between those with and without biliary complications.

Conclusions: These data show that transplantation volume and 1-year survival trended upwards and 5-year survival has significantly improved at our institution. This improvement has occurred without a change in biliary complication rates or overall complication severity, and patients with biliary complications were shown to survive comparably to those without. This suggests that, although biliary complications may occur in a large proportion of patients, current treatments for these complication are effective and the rate of graft failure requiring re-transplantation is low. Our data also may suggest improved peri- and post-operative care, resulting in improved outcomes. Thus, DCD liver transplantation remains a viable option and may continue to comprise a growing number of transplantations.

Abstract# 1162

Living Donor versus Deceased Donor Pediatric Liver Transplantation: A Systematic Review and Meta-Analysis of Outcomes

A. Barbetta[1], C. Butler[2], S. Barhouma[2], R. Hogen[1], B. Roque[1], H. Schillperoort[3], G. Meeberg[4], J. Shapiro[5], Y. Kwon[1], R. Kohli[6], J. Emamaullee[1], *[1]Surgery, abdominal transplat, University of Southern California, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, [3]Norris Medical Library, University of Southern California, Los Angeles, CA, [4]Department of Surgery, University of Alberta, Edmonton, AB, Canada, [5]Department of Surgery,, University of Alberta, Edmonton, AB, Canada, [6]Department of Pediatrics, University of Southern California, Los Angeles, CA*

Purpose: Reduced size deceased donors and living donor liver transplantation (LDLT) can help address the organ shortage for pediatric liver transplant candidates. Concerns regarding technical challenges and the risk of postoperative complications have been raised when using segmental grafts in children, leading to variable practice patterns in utilization of these grafts. We sought to compare outcomes for pediatric LDLT and DDLT via systematic review and meta-analysis.

Methods: A systematic literature search was performed to identify studies reporting outcomes of pediatric (<18 year) LDLT and DDLT published between 2005-2019. Unpublished data from an additional high-volume Canadian center were included. Perioperative and survival outcomes were pooled and compared using fixed- and random-effects models.

Results: Overall, 2518 abstracts were screened, and 10 studies met criteria for inclusion. In total, 1622 pediatric LDLT and 6326 pediatric DDLT patients from four continents were examined. LDLT recipients had superior overall survival when compared to DDLT recipients at 1, 3, and 5-years post-LT [1year HR: 0.56 CI 95% 0.45-0.71, p<0.0001] (Fig 1A). Similarly, LDLT resulted in superior graft survival at all time points post-LT when compared to DDLT [1-year graft survival, HR: 0.47 95% CI: 0.37-0.61, p<0.0001] (Fig 1B). LDLT was associated with higher PELD at LT. There was no difference in the rate of post-LT vascular or biliary complications, while LDLT was associated with lower rates of acute cellular rejection [OR: 0.66 (95% CI: 0.45-0.96), p=0.03] (Fig 1C).

Conclusions: Our global meta-analysis demonstrates that LDLT offers many advantages when compared to DDLT in children and suggests that LDLT should continue to be expanded to optimize outcomes in pediatric liver transplant recipients.

Abstract# 1163

Immunologic Benefits of Maternal Living Donor Allografts in Pediatric Liver Transplantation: Less Rejection Episodes and No Evidence of De Novo Allosensitization

A. Barbetta[1], G. Meeberg[2], B. Rocque[1], S. Barhouma[3], S. Gilmour[4], F. Faytrouni[5], O. Guttman[5], P. Campbell[4], J. Shapiro[2], J. Emamaullee[1], *[1]Surgery, Abdominal Transplant, University of Southern California, Los Angeles, CA, [2]Surgery, University of Alberta, Edmonton, AB, Canada, [3]University of Southern California, Los Angeles, CA, [4]University of Alberta, Edmonton, AB, Canada, [5]University of British Columbia, Vancouver, BC, Canada*

Purpose: Living donor liver transplantation (LDLT) offers improved graft and patient survival in pediatric liver transplant (LT) recipients. Prior studies have suggested immunological advantage when using maternal living liver donors (LLDs), with less rejection episodes. It is unclear if this benefit extends to reduce risk of developing donor-specific antibody (DSA) and crossmatch positivity among maternal donors and child recipient pairs. The aim of this study was to evaluate immunologic outcomes following pediatric LT, comparing maternal LLD grafts to non-maternal LLD and deceased donor (DD) grafts.

Methods: Children (<18 years) who underwent LT between January 2005-December 2017 at a single, high volume center where retrospective crossmatch is routinely performed were evaluated. Patients were divided in 3 groups according to type of graft received (maternal LLD, non-maternal LLD, and DD). Clinical variables and outcomes were compared using the Fisher exact test for categorical variables and Kruskal-Wallis test for continuous variables. Patient and graft survival were analyzed using the Kaplan-Meier method.

Results: A total of 110 pediatric LT recipients met inclusion criteria. In the study period, 58 (52.7%) children received a DD graft, 34 (10.9%) received non-maternal LLD and 18 (16.4%) received a maternal LLD graft. There were no differences in demographics, PELD, medical status at transplant, ABO compatibility, or crossmatch positivity among the three groups. Children receiving living liver donor graft were less likely to develop rejection when compared to the DD group (DD 71.2% vs Maternal LLD 46.7% vs non-maternal LLD32.4%, p=0.001). Among patients were tested for pre-transplant DSA, 6 DD recipients, 2 maternal and 2 non-maternal LLD recipients had pre-formed DSA. Post-transplant, de novo DSA were identified in 5 DD and 3 non-maternal LLD recipients. No recipients of maternal LLD grafts developed de novo DSA. Only 4 patients had both pre-formed and de-novo DSA, but none of the patients with positive DSA developed antibody mediated rejection. There were no differences in overall patient and graft survival among the three cohorts.

Conclusions: These data support the concept of immunologic benefit of maternal LLD in pediatric LT, with lower rates of rejection and no evidence of allosensitization post-LT. Recipients of maternal LLD grafts be examined as potential candidates for immunosuppression minimization and withdrawal protocols

Post Pediatric Liver Transplant Immunosuppression: What's the Caregivers' Perspective?

I. D. Batsis[1], J. C. Bucuvalas[1], E. Eisenberg[2], J. Lau[2], S. Feng[3], E. Perito[4], *[1]Pediatric Hepatology, Mount Sinai Hospital, NY, New York, NY, [2]Patient and Family Engaged Partners, SPLIT, New York, NY, [3]Pediatric Transplant Surgery, UCSF, San Francisco, CA, [4]Pediatric Hepatology, UCSF, San Francisco, CA*

Purpose: For children with liver transplants (LT), achieving an "ideal outcome" is a balancing act: too little immunosuppression (IS) begets graft injury; too much IS begets systemic toxicities. Our aim was to delineate the patient/family perspective on this critical tightrope.

Methods: A brief, 13 question survey (English) was sent to parents/guardians of children who had LT at <18yo via patient advocacy group listservs (Society of Pediatric Liver Transplant, Starzl Network for Excellence in Pediatric Transplant) and social media (Facebook, Twitter). Caregivers were asked to prioritize their top concerns; rate their level of concern/level of certainty about IS complications and rejection from 1 (not concerned or completely uncertain) to 10 (extremely concerned or absolutely certain).

Results: 76 caregivers responded. Children had LT at 0-2y (77%), 3-11y (16%), 12-18y (7%). At survey, median recipient age was 4y (IQR 2-9y; range 0-22y); 73% were currently receiving IS monotherapy. Caregivers' top concerns about IS were related to IS toxicity and infection risk (FIG). 46% were more concerned about IS complications than rejection, vs only 17% more concerned about rejection than IS toxicity; 37% were equally concerned. Among caregivers of children receiving IS monotherapy, more worried about IS toxicity than rejection, 48% expressed equal

concern for both. Caregiver's level of concern about rejection was higher for children on more than 1 (28%) vs 1 IS agent (72%): median (IQR) scores of 85 (61-100) vs 70 (47-90); p=0.07. Time since LT (0-4yrs vs >4yrs) was not associated with concern level for rejection or IS complications. Caregivers were significantly more certain that their child's IS regimen was correct to prevent rejection than mitigate IS toxicity: scores of 90 (70-100) vs 65 (40-87); p<0.005. Neither time since LT nor number of IS medications were associated with caregivers' certainty levels.

Conclusions: Caregivers of children with LTs are more concerned that IS risks toxicity than rejection. In parallel, they are more certain that IS dosing is appropriate to prevent rejection than to avoid toxicity. In the integrated, patient-centered model of active patients/caregivers and receptive clinicians, understanding the caregiver perspective in long-term IS management is critical and can help guide management toward ideal outcomes, as caregiver priorities and concerns may differ from their providers.

Abstract# 1165

Developmental Characteristics and Haemodynamics After Pediatric Donor to Adult Recipients in Liver Transplantation

M. Chen, L. Xiaohong, H. Xitao, C. Zhitao, J. W., *Transplant Center, Sun Yat-sen University, Guangzhou, China*

Purpose: The developmental characteristics and hemodynamics of pediatric liver allografts transplanted into adult recipients remain unclear and deserve exploring.

Methods: Records from adult recipients undergoing liver transplantation between January 2015 and December 2019 who received whole grafts from pediatric (<14 years, Experimental group) or adult (18-35 years, Control group) donors were reviewed.

Results: The study comprised 312 subjects, divided between the pediatric (n = 67) and adult donor (n = 245) groups. The 1, 3 and 5-year recipient survival rates were 87.3%, 83.3%, and 83.3% in the pediatric group, and 88.6%, 85.7%, and 85.7% in the adult group. One adult recipient receiving a pediatric allograft developed small-for-size liver syndrome (SFSS) post-transplantation. There was no difference in the incidence of portal vein thrombosis, biliary complications, primary graft non-function, or prolonged cholestasis between the two groups. As expected, the recipients in the pediatric group had a lower graft-to-recipient weight ratio (GRWR) (1.16±0.32) and graft weight (GW)/ estimated recipient liver weight (ERLW) (0.73±0.23) than the adult group (2.25±1.70, 1.45±0.40, p<0.01). Evaluation at 1 year from transplant demonstrated that the recipient's right hepatic oblique diameter, diameter of main portal vein (DPV) and resistance index (RI) were not significantly different between the two groups (P>0.05). The velocity of the main portal vein (VPV) and velocity of Hepatic artery (VHA) in the pediatric group was almost always higher than the adult group throughout the first year of transplantation, but eventually all returned to normal range.

Conclusions: The pediatric donor liver can be successfully used in adult recipients with well-matched conditions. There were no significant differences in postoperative hemodynamics and the grafts developed and functioned normally.

Abstract# 1166

Portal Vein Challenges in Pediatric Liver Transplantation: The Utility of Interposition Grafts as an Acceptable Management Strategy

R. Hogen, K. Etesami, J. Cervantes, Y. Kwon, S. Zielsdorf, J. Emamaullee, Y. Genyk, *Division of Hepatobiliary and Abdominal Organ Transplantation, Keck School of Medicine of USC, University of Southern California, Los Angeles, CA*

Purpose: To examine our single center experience in the operative management of pediatric liver transplantation (LT) patients with challenging portal vein (PV) anomalies.

Methods: We retrospectively reviewed the records of LTs performed at Children's Hospital Los Angeles from 2004-2020. The incidence of portal vein thrombosis (PVT), atresia (PVA), and hypoplasia (PVH), operative management, and post-operative outcomes were noted. The Yerdel classification was used to classify PVT. We analyzed survival outcomes using a Kaplan-Meier estimator.

Results: From 2004-2020, 330 pediatric LTs were performed. 22 patients (7%) had PVT (4 grade 1, 10 grade 2, 2 grade 3, 5 de-novo intra-operative, 1 unclassified), 1 (0.3%) patient had PVA, and 11 (3%) patients had PVH. The prevalence of PVT and PVH was highest in patients with BA followed by hepatoblastoma (Figure 1). 10 of 11 PVHs and one case of Abernathy malformation (PVA) were managed with a cadaveric external iliac vein interposition graft (CVG). 15 of 22 PVTs (1/4 grade 1, 8/10 grade 2, 2/2 grade 3, 3/5 de-novo) were managed with CVG. The remainder of the PVTs were managed with thrombectomy. One CVG was performed for a short PV. There was no statistically significant difference in post-operative PV complications (11% (3/27) vs. 0% (0/8); p = 1.00), re-operation for bleeding (3.7% (1/27) vs. 12.5% (1/8); p = 0.41), or LOS (30 vs. 36 days; p = 0.77) between the patients managed with CVG and those without. There were no post-operative PV complications observed in living donor grafts. Median follow up was 1381 days. There was no statistically significant difference in graft or patient survival between patients managed with CVG and those without (Figure 2).

Conclusions: PVT, PVA, and PVH can present as challenging cases in pediatric LT. A primary construct with or without thrombectomy should be utilized when amenable. However, many circumstances arise when thrombectomy is inadequate or the native vessel itself is of critically small caliber. As we have shown, such instances can safely and successfully be managed utilizing a CVG with excellent outcomes.

Figure 1: Patient Characteristics:

	CVG	No CVG	p-value
Patients	27	8	
Mean age (yr)	4.8	7.3	0.39

Abstract# 1167

Adults Undergoing First Time Liver Transplantation with Biliary Atresia: An Analysis of the United Network for Organ Sharing Database

E. Hsu[1], J. Perkins[2], S. P. Horslen[1], A. A. Dick[1], N. M. Blondet[1], J. D. Reyes[2], *[1]Seattle Children's Hospital, Seattle, WA, [2]Surgery, University of Washington School of Medicine, Seattle, WA*

Purpose: Although biliary atresia (BA) is the most common indication for liver transplantation in children, there is no published data on outcomes for individuals who survive into adulthood with their native liver. In order to better counsel this subset of patients as they transition from pediatric to adult care, we utilized national transplant registries over a 16-year period to characterize waitlist and post-transplant outcomes.

Methods: We conducted a retrospective analysis of all candidates on the United Network for Organ Sharing (UNOS) waitlist from February 2002 until September 2018 listed for first liver transplant with a primary diagnosis of BA, and with transplant occurring after the candidate's 18th birthday. We performed a 5:1 propensity matched analysis for recipients with other chronic liver diseases.

Results: Over the 16-year range of the study, 283 individuals met criteria for inclusion for the analysis. 26 (9.2%) died on the wait list, and 158 (55.8%) were transplanted. The remainder were still listed at time of analysis or removed for no longer requiring transplant. Median age at end-event was 24.8 years. Individuals who died on the waitlist had higher MELD scores, fewer exceptions, and were over-represented by Black and Hispanic race. The majority of candidates transplanted in adulthood for BA were in their 3rd decade of life and waited for a transplant more than 3 years on average. 8% had a TIPS in place and more than 5% had a co-diagnosis of hepatocellular carcinoma. Post-transplant outcomes were comparable to individuals with BA transplanted in childhood and with adults on the waitlist with cholestatic liver disease.

Conclusions: Patients surviving into adulthood with BA and their native liver may require transplantation beyond the 2nd decade of life. The majority of these transplants are occurring at or after a transition of healthcare teams and healthcare coverage. Despite these challenges, post-transplant graft and survival outcomes are excellent.

Abstract# 1169

Clearance of Viral RNA and DNA and Antibody Response Following Administration of Live Attenuated Measles and Varicella Vaccines in Children with Chronic Liver Disease

S. Kemme[1], A. Weinberg[2], A. G. Feldman[1], *[1]Children's Hospital Colorado, Denver, CO, [2]University of Colorado Denver, Denver, CO*

Purpose: Guidelines recommend waiting four weeks between live vaccine administration and transplantation; however, there is little data to support this waiting period and it often results in delay in transplantation, passage on an optimal organ, or foregoing the opportunity to vaccinate. The purpose of this project is to 1) define the time post-vaccination at which measles and varicella viruses become undetectable in the blood of children with liver disease and 2) determine whether children with chronic liver disease awaiting transplant mount a protective immune response to live vaccines.

Methods: 6 children with chronic liver disease were enrolled and demographic and clinical information were collected. Viral PCRs for measles and varicella were measured weekly for four weeks post-vaccines. Antibodies (Ab) were measured pre-vaccine and again four weeks post-vaccines.

Results: 6 children (2 with Biliary Atresia, 2 with Alagille Syndrome, 1 with PFIC, and 1 with undefined cirrhosis) received live vaccines between 6-13 months of age. All patients cleared measles and varicella by two weeks post-vaccines. A majority of children mounted a protective antibody response against measles and varicella. (Table 1)

Conclusions: In this pilot study, no children with chronic liver disease were viremic for measles or varicella beyond two weeks post-vaccination and a majority mounted a protective antibody response. This suggests the four week waiting interval between vaccines and transplant may be unnecessary.

Table 1: PCR and Antibody Results

Subject # (Age at Vaccination)	#1 (12 mo)	#2 (11 mo)	#3 (6 mo)	#4 (13 mo)	#5 (13 mo)	#6 (12 mo)

Abstract# 1170

Outcomes After Abo Incompatible Pediatric Liver Transplantation are Comparable to Abo Identical/compatible Transplant

C. Lemoine, K. Brandt, R. Superina, *Division of Transplant and Advanced Hepatobiliary Surgery, Ann & Robert H. Lurie Children's Hospital, Northwestern University Feinberg School of Medicine, Chicago, IL*

Purpose: In order to evaluate if the incidence of vascular and biliary complications as well as patient and graft survival in ABO incompatible (ABOi) liver transplant (LT) are comparable to ABO compatible/identical (ABOc) LT, we reviewed our institutional experience with ABOi LT, comparing the early and modern eras of our program, and then comparing ABOi LT outcomes to those after ABOc LT.

Methods: A retrospective review of all patients who received an ABOi LT at our institution was performed (1997-2020). Two eras were created for comparison (early: 1997-2008, modern: 2009-2020). A pair-matched comparison was also done with patients who received an ABOc LT at our institution (matching criteria: transplant year, age and PELD score/status at transplant, indication for LT). Independent t-test, Chi-square test, and Kaplan-Meier survival curves were used for statistical analysis ($p<0.05$ considered significant).

Results: 17 patients (9 female) received 18 ABOi LT (3 retransplants). Median age at transplant was 7.4 months (1.1-28.9). At the time of LT, 66.7% patients (12/18) were listed as status 1 (status 1 before 2002, or status 1A or 1B after 2002). The 6 other patients had a median PELD score at transplant of 36.5 (27-48). Hepatic artery thrombosis (HAT) occurred in one patient (5.6%), there were 2 cases of portal vein thrombosis (PVT) (11.1%), and 4 biliary complications (22.2%). Patient and graft survival improved in the ABOi modern era, although not significantly: early patient survival, 5/8, 62.5% vs. modern 8/9, 88.9%, (p=0.20), and early graft survival, 5/8, 62.5% vs. modern 8/10, 80.0%, (p=0.41). In the pair-matched comparison, frequency of complications was similar (HAT: ABOi 1/18, 5.6% vs. ABOc 3/18, 16.7%, p=0.29; PVT: ABOi 2/18, 11.1% vs. ABOc 4/18, 22.2%, p=0.37; biliary complications: ABOi 4/18, 22.2%, vs. ABOc 1/18, 5.6%, p=0.15). Overall patient (ABOi 13/17, 76.5% vs. ABOc 14/17, 82.4%, p=0.62) and graft (ABOi 12/18, 66.7% vs. ABOc 13/18,

72.2%, p=0.72) survival were also similar. Patient and graft survival was 100% in the non-status 1 ABOi patients, compared to 67% (p=0.11) and 58% (p=0.063) respectively for ABOi patients who were status 1.

Conclusions: ABO incompatible liver transplants in children < 1-year of age and high PELD scores have excellent outcomes and should be used routinely. Status 1 infants have similar patient and graft survival and complication rates to ABO compatible or identical transplants. ABO incompatible transplants should be utilized more frequently in order to prevent deaths on the waiting list or deterioration of children with high PELD scores.

CITATION INFORMATION: Lemoine C., Brandt K., Superina R. Outcomes After Abo Incompatible Pediatric Liver Transplantation are Comparable to Abo Identical/compatible Transplant *AJT, Volume 21 Supplement 3*

Abstract# 1171

Thrombotic and Hemorrhagic Complications Associated with Postoperative Anticoagulation After Pediatric Liver Transplantation

C. Lemoine, K. Brandt, R. Superina, *Division of Transplant and Advanced Hepatobiliary Surgery, Ann & Robert H. Lurie Children's Hospital, Northwestern University Feinberg School of Medicine, Chicago, IL*

Purpose: In order to determine the efficacy of post-liver transplant (LT) anticoagulation protocols in reducing the occurrence of arterial thrombosis (HAT) and other vascular complications in children, we compared the rate of thrombotic complications after LT and the incidence of bleeding complications associated with both prophylactic and therapeutic post LT anticoagulation protocols.

Methods: A retrospective review of our prospectively collected LT database was performed over a 5-year period (2014-2018). At our institution, heparin is used in all patients after LT but therapeutic dosing is used only when a patient has had a thrombotic event during or after LT or had less than ideal hepatic artery or portal venous flow at the end of the LT. Results were compared between prophylactic (Ppx) vs. therapeutic (Tx) heparin groups. Independent t-test and Chi-square test were used for statistical analysis ($p<0.05$ considered significant).

Results: 69 patients received 73 LT. Median age and weight at LT were 2.3 years (40 days-18.9 years) and 13.4 kg (3.3-88.9). The Ppx protocol was used in 52/73 (71.2%) LT. Heparin was stopped in 10/52 patients in the Ppx group (19.2%) due to bleeding compared to 8/21 (38.1%) in the Tx group (Ppx vs. Tx, p=0.090). Within the first 72 hours after LT, the blood transfusion requirements were similar in both groups (Ppx 25.5±42.3 cc/kg vs. Tx 37.0±43.2 cc/kg, p=0.30). The number of patients requiring massive transfusion within 72 hours post LT was not significantly different (Ppx 4/52 7.7% vs. Tx 4/21 19.0%, p=0.16). Patients from the Tx group were taken back to the operating room (OR) more frequently for complications related to bleeding (Ppx 7/52, 13.5%, vs. Tx 10/21, 47.6%, p=0.002). Patients in the Ppx group were taken back to the OR for bleeding significantly sooner after LT (Ppx 1.7±1.6 vs. Tx 4.2±2.0 days, p=0.015). Overall, 4/73 transplants had HAT (5.5%): 1/52 (1.9%) in the Ppx vs. 3/21 (14.3%) in the Tx group (p=0.036). 3 HAT occurred in patients already on Tx protocol due to concerns with hepatic artery flow or thrombosis at the time of LT. Portal vein thrombosis (PVT) occurred in 5 occasions (5/73, 6.8%). All PVT occurred in patients from the Tx group (Ppx 0/52, 0%, vs. Tx 5/21, 23.8%, p<0.001). There were no hepatic venous outflow obstruction events. Median follow-up was 2.3 years (15 days-5.6 years). Overall patient (Ppx 96.2% vs. Tx 95.2%, p=0.86) and graft (Ppx 92.3% vs. Tx 81.0%, p=0.16) survival were not statistically different between groups.

Conclusions: The use of an anticoagulation protocol after pediatric liver transplantation was associated with a low rate of hepatic artery and portal vein thrombosis. Therapeutic anticoagulation was associated with more bleeding complications, but without adversely affecting patient or graft survival.

Abstract# 1172

Perivenular Fibrosis After Pediatric Liver Transplant

J. Lew, S. Cho, S. Feng, E. R. Perito, *UCSF, San Francisco, CA*

Purpose: Graft fibrosis is a concerning long-term complication after pediatric liver transplant (LT) and though perivenular (PV) fibrosis is common, its likelihood of progression and clinical significance are unclear; we seek to investigate PV fibrosis prevalence and both clinical and histologic associations.

Methods: We conducted a single-center, retrospective, cohort study of children (0-18 years at LT) who had undergone surveillance liver biopsies (2006-2020). Biopsies were reviewed and scored for 15 features according to a standardized protocol by 2 pathologists. PV fibrosis was scored as 0, none; 1, mild; or 2, moderate/severe.

Results: We reviewed 96 children (56% male; 49% biliary atresia; 55% partial grafts; 31% living donors) who underwent 118 surveillance biopsies; 22 had 2 biopsies. First biopsy was done at median (IQR) 8.7 (5.1-13.4) years after LT with ALT 27 (20-41) U/L and GGT 15 (12-32) U/L; 43%, 44%, and 13% showed no, mild, and moderate/severe PV fibrosis. Neither PV fibrosis presence nor severity was associated with donor or graft type, bile duct damage, portal inflammation or portal fibrosis (FIG). The 22 paired biopsies were separated by median 4.6 (3.0-5.5) yrs. PV fibrosis regressed for 8 and progressed for 5. Among regressors 3, 3, and 2 had increased, stable, and reduced immunosuppression, respectively. Among progressors, 1, 2, and 2 had increased, stable, and reduced immunosuppression, respectively. No progressors had portal fibrosis or interface activity on either biopsy, nor vascular or biliary complications between biopsies.

Conclusions: PV fibrosis is present in the majority of pediatric LT surveillance (normal liver tests) biopsies but is most commonly mild and remains stable over time. PV fibrosis is not associated with histologic features of rejection. Longitudinal study of sequential biopsies is needed to understand the causes and impact of PV fibrosis, and to inform its impact on long-term immunosuppression management.

Abstract# 1173

Peripheral Lymphocyte Profiling and Increased Risk of EBV Infection in Pediatric Liver Transplant Recipients

V. M. Novara Gennuso[1], T. Miloh[2], *[1]Pediatrics, Miller School of Medicine-University of Miami, Miami, FL, [2]Pediatrics, Miami Transplant Institute, Miami, FL*

Purpose: Epstein-Barr virus "EBV" infection and post-transplant lymphoproliferative disorders "PTLD" are significant comorbidities in the post-transplant "PT" setting, especially in pediatrics. The synergy among T cell subpopulations (e.g. CD4+ T-helpers, CD8+ T-cytotoxic) modulates immune response. The rationale behind this study was to assess whether peripheral lymphocyte subtype analysis of different subsets was associated with increased risk of EBV infection in children PT.

Methods: Between Feb 2010 and Jan 2020, 174 patients received a liver transplant "LT". 39 of these patients (22.4%) had lymphocyte subset profiling at some point. These patients were reviewed 3 months before positive EBV status or 2 months after positive EBV status. EBV positivity was defined as plasma PCR levels >158 copies/mL. EBV PCR was checked monthly in the first year PT, every 3 months in the second year PT, and annually after the third year PT. Reactivation was designated as IgG positive at time of LT, and new viral infection, as IgG negative at time of LT. Statistical significance of values was obtained using the regression analysis tool in Microsoft Excel by comparing the average of peripheral lymphocyte profiles of positive EBV and non EBV patients.

Results: 8/39 patients who met inclusion were EBV positive (20.5%). 7 (87.5%) had reactivation, and 1 had new viral infection. The average time from LT to positive EBV was 3.9 years. The average age at LT was 1.2 years for positive EBV patients in comparison to 3.4 years for non EBV patients. Indications for LT: 3 had diagnosis of Biliary Atresia, 2 Ornithine Transcarbamylase deficiency, 1 Graft failure, 1 Maple Syrup Urine disease, and 1 Crigler-Najjar syndrome. All EBV positivity led to decreased immunosuppression. There was no PTLD noted. Lymphocyte profiling is shown in Table 1. Overall, EBV positive patients had lower circulating T cells (68.7%), higher B cells (20.9%) and Natural Killer cells (9%). CD4 T Helper lymphocytes were higher in positive EBV patients (31.4%). The CD4/CD8 ratio cells were the highest in positive EBV patients (1.7) and lowest in non EBV patients (1.2). ($P<.001$ Table 1).

Conclusions: CD4 T Helper lymphocytes were higher in positive EBV and the CD4/CD8 ratio was significantly higher during active EBV infection and reactivation. Therefore, the risk of concomitant rejection is lower and decreased immunosuppression is well tolerated. Future larger controlled studies are needed to validate these findings and may offer development of non-invasive markers to diagnose EBV infection.

Abstract# 1174

Paired Surveillance Biopsies Over >4 Years from a Multi-Center Cohort of 78 Long-Term Pediatric Liver Transplant Recipients

E. R. Perito[1], E. Persyn[2], J. Bucuvalas[3], J. E. Squires[4], M. Martinez[5], S. Mohammad[6], A. J. Demetris[4], S. Feng[1], *[1]UCSF, San Francisco, CA, [2]King's College, London, United Kingdom, [3]Mt. Sinai School of Medicine, NY, NY, [4]U of Pittsburgh, Pittsburgh, PA, [5]Columbia U, NY, NY, [6]Northwestern U, Chicago, IL*

Purpose: Progressive liver fibrosis threatens graft and patient longevity for children after liver transplantation (LT). Previous studies are limited to single-center, cross-sectional analyses. To address this knowledge gap, we examined prevalence of progressive allograft fibrosis in sequential surveillance biopsies from 78 pediatric LT recipients from 11 centers.

Methods: Biopsies from 78 children (43 prospectively, 35 retrospectively, 0 LT for viral or autoimmune hepatitis) assessed by 1 central pathologist; paired biopsies compared side-by-side. Serum ALT and GGT levels were <40 U/L, index biopsy ≥4 yrs after LT, 2nd biopsy ≥4 yrs later. Fibrosis was staged by the liver allograft fibrosis score (LAFSc 0-9; 0 none, mild 1-2, moderate 3-5; severe 6-9) on H&E, trichrome stains. Significant fibrosis progression or regression was defined as LAFSc increase or decrease by ≥3.

Results: Of 78 children, 51 were male, 44 had biliary atresia, 50 had living donors. Index biopsy was done at a median (IQR) 8.2 (5.9-11.6) yrs after LT with 89% on immunosuppression monotherapy, ALT 24 (19-35), GGT 15 (12-22) U/L. Fibrosis was none/mild in 29%, moderate in 56%, and severe in 14%. 2nd biopsy was done a median (IQR) of 4.7 (4.3-5.1) yrs later, at 13.8 (10.9-16.8) after LT, with 91% on monotherapy, ALT 25 (19-37), and GGT 17 (14-28) U/L. The majority (56%) had minimal LAFSc change (-1, 0, +1; FIGURE): 10 (13%) progressed (7 mild to mod) and 4 (5%) regressed (mod to mild). After adjusting for baseline LAFSc, progression was associated with younger age at LT [median (IQR) 0.7 (0.6-1.0) vs. 1.3 (0.6-2.0) yrs; p=0.02] but not with donor/graft type, time from LT to 1st or 2nd biopsy, time between biopsies, or ALT/GGT/inflammation at 1st biopsy. None had biliary or vascular complications. 8 of 10 with progression were on less IS at 2nd biopsy, as were 33% of those with stable/improved fibrosis.

Conclusions: In our multicenter cohort, at 8 and 14 years after LT, only 14% and 19% respectively, of surveillance biopsies showed severe fibrosis. Progression was uncommon, seen in only 13%. This differs distinctly from previously reported cohorts, which may reflect a more modern, tacrolimus-based regimen and the subset of children studied. Our low prevalence of severe or progressive fibrosis suggests that non-invasive fibrosis assessment could be a useful adjunct in long-term monitoring for children with normal transaminases.

Abstract# 1175

A Pediatric Liver Allograft with an Occult Urea Cycle Defect Carrier Mutation Causing Delayed Graft Function and Metabolic Crisis After Liver Transplantation

A. Peters, M. Rezvani, C. Prada, K. Campbell, *Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Purpose: We report an interesting case of delayed graft function following pediatric liver transplantation, which was attributed to previously unrecognized urea cycle carrier genetic defect in the allograft liver.

Methods: This is a retrospective chart review.

Results: A 5 month old African-American female infant with blood type AB+ underwent whole organ ABO-compatible deceased donor liver transplantation for unpalliated biliary atresia. The donor was a 17 month old African-American female infant, blood type A+, with no significant past medical history. The transplant operation itself was uncomplicated and only the skin layer of the abdomen was closed. The recipient was extubated on post-operative day (POD) 1, however, later that day was somnolent and hyperreflexic concerning for hepatic encephalopathy. Laboratory values were concerning for primary nonfunction of the allograft, with ALT 2397, AST 3318, INR 6.68, Ammonia 144, and lactate was normal. The recipient was re-intubated and continuous renal replacement therapy for clearance of ammonia was initiated on POD2-4. The recipient was listed for retransplantation at status 1A for primary nonfunction. However, lab indices slowly improved with ammonia level 36, AST 37, ALT 271, and INR 1.03 by POD6. The recipient returned to the OR on POD 6 for fascial closure. An opportunistic liver biopsy showed steroid effect on hepatocytes, normal liver architecture, mild canalicular cholestasis, and no evidence of hepatocyte necrosis or acute cellular rejection. The recipient's allograft function slowly recovered and she was removed from the transplant list. Due to hyperammonemia despite CRRT, the question was raised regarding a potential urea cycle defect present in the allograft liver. After communicating with the organ procurement organization, DNA was obtained from remaining donor PBMC. Genetic testing for urea cycle defects was performed, which showed that the donor liver carried a heterozygous pathogenic mutation in the *ASL* gene encoding the urea cycle enzyme, arginosuccinase. This enzyme catalyzes the breakdown of arginosuccinate into fumarate and arginine. Individuals who are homozygous for *ASL* mutations have frequent metabolic crises in response to catabolic states including illness and fasting. Carriers can also have crises under extreme metabolic stress. It is thought that the ischemia-reperfusion stress on the allograft liver led to a metabolic crisis in the recipient that masqueraded as primary nonfunction. With supportive care the recipient made a full recovery. LFT normalized and she was discharged from the hospital on POD 39.

Conclusions: When faced with rare complications following liver transplantation including primary nonfunction, metabolic liver disease within the allograft should be considered. Genetic testing on remaining DNA from the donor can confirm the presence of metabolic disease.

Abstract# 1176

Macrosteatosis in the US Pediatric Deceased Liver Donor Population, 2005-2018

J. Purvis, D. Dhall, C. McLeod, S. Sheikh, R. Cannon, K. Frey, J. Locke, B. Orandi, *University of Alabama School of Medicine, Birmingham, AL*

Purpose: The pediatric obesity epidemic is associated with early signs of non-alcoholic fatty liver disease (NAFLD) such as increased hepatic macrosteatosis and liver enzymes. In adults, donor macrosteatosis in liver allografts is associated with graft loss, but this association has not been examined in pediatric donors.

Methods: Our study included all pediatric potential whole liver donors from 2005-2018 who had a liver biopsy in the Scientific Registry for Transplant Recipients (SRTR) (n = 862) and their recipients (n = 862). Macrosteatosis was abstracted from biopsy reports uploaded to DonorNet and compared to values in the SRTR standard analytic file. If the biopsy report was missing, the SRTR value was used. If the two sources differed, the value in the biopsy report was used preferentially. Recipients of pediatric macrosteatotic liver grafts (>5% macrosteatosis; n = 193) were matched 1:1 to recipients of pediatric non-macrosteatotic grafts (<5% macrosteatosis) by propensity score matching on donor and recipient variables. All-cause graft loss was estimated via Kaplan-Meier analysis and a Cox proportional hazards model was fit with adjustment by covariates that remained unbalanced after matching.

Results: From 2005-2018, there was a significant increase in the proportion of biopsied pediatric liver donors with macrosteatosis (26.7% in 2005 and 41.5% in 2018; P < 0.001), consistent with a significant increase in pediatric donor BMI over the study period (Figure 1). Over the study period, the median degree of macrosteatosis among macrosteatotic donors was 10% (IQR 5-30). From 2005-2018, the proportion of biopsied deceased pediatric whole liver donors >2 years old were obese based on BMI percentile for age and sex increased from 17.3% to 37.7% (P = 0.002). On Kaplan-Meier analysis, there were no significant differences in all-cause graft loss

between the two groups at 90 days (stratified log-rank, P = 0.14) or 8 years (stratified log-rank, P = 0.27) post-transplant. A Cox proportional hazards model also showed no significant difference between the groups at 90 days (HR = 0.48; 95% CI = 0.18-1.27) or 5 years (P > 0.05) post-transplant.

Conclusions: Pediatric liver donors between 2005-2018 became more obese with a greater proportion of macrosteatosis. Macrosteatosis did not appear to adversely affect outcomes, but if current trends in obesity and macrosteatosis continue, this might change.

Abstract# 1177

Temporal Changes in Renal Function Predict Waitlist Death or Deterioration in Pediatric Liver Transplantation

N. Thalji, L. Thalji, S. Ibrahim, T. Diwan, P. Kamath, J. Heimbach, *Mayo Clinic Rochester, Minnesota, Rochester, MN*

Purpose: Renal dysfunction at the time of listing predicts inferior waitlist outcomes in pediatric liver transplant candidates, independent of the Pediatric End-Stage Liver Disease (PELD) score. We test the hypothesis that temporal changes in post-transplant listing renal function also impact waitlist death or deterioration.

Methods: We studied all pediatric patients <12 years old registered for liver-only transplantation in the United States between Feb 2002-Dec 2018. Status 1A listings were excluded. Patients were stratified into categories of high (eGFR≥90mL/min/1.73m^2), intermediate (eGFR 60-89 mL/min/1.73m^2) or low eGFR (eGFR<60mL/min/1.73m^2 or on dialysis) at transplant registration. Multivariable logistic regression models were used to assess the impact of improving and worsening eGFR on 90-day waitlist death/deterioration.

Results: A total of 4,578 patients met study criteria. Median (inter-quartile) age was 1 (0-3) year, and 50% (2,267) were male. Overall, 80% (3,654) of patients proceeded to transplant, and 6.5% (298) died or deteriorated beyond transplantability. At listing, 80.5% (3,553) had high eGFR, 14.6% (644) had intermediate eGFR, and 4.9% (217) had low eGFR. At waitlist removal, renal function had improved to a higher eGFR category in 7.1% (315) of patients, and 14.9% (658) had worsening of renal function to a lower eGFR category, compared to listing measurements. Adjusting for PELD score, odds of 90-day waitlist death/deterioration markedly increased in patients with worsening eGFR versus those in whom it was unchanged (OR 3.71, 95%CI 2.67-5.16; p<0.001). This was clear in subsets with high (OR 6.41, 95%CI 4.24-9.66) or intermediate eGFR (OR 3.51, 95%CI 1.60-7.69) at transplant listing (both p<0.001). Though a trend toward favorable 90-day outcomes in patients with improved eGFR did not reach significance for the overall cohort, in those with the lowest category eGFR at listing, improvements in renal function were associated with an 8-fold reduction in odds of 90-day death/deterioration (OR 0.13, 95%CI 0.04-0.48; p=0.002). (Figure)

Conclusions: Worsening waitlist renal function independently predicts 90-day death/deterioration in pediatric liver transplant candidates. In those with the lowest eGFR at registration, temporal improvements in renal function were associated with favorable outcome. These data highlight prognostic merits of aggressively managing waitlist kidney dysfunction, while further supporting integration of renal function parameters in the process of liver allocation to pediatric transplant candidates.

Probability of 90d Wait-List Death or Deterioration by Listing and Final Renal Function *

Abstract# 1178

Clinically Evident Portal Hypertension (CEPH) is Associated with Low IGF-1 in Children with Chronic Liver Disease

B. Whitehead[1], S. Mohammad[1], S. Kelly[1], J. Josefson[2], L. Mithal[3], E. M. Alonso[1], *[1]Division of Gastroenterology, Hepatology and Nutrition, Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [2]Division of Endocrinology, Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [3]Division of Infectious Disease, Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL*

Purpose: Children with chronic liver disease exhibit growth hormone resistance which is an additional risk factor for sarcopenia and growth failure in this vulnerable population. Low IGF-1 is associated with multiple negative effects including fatigue in other pro-inflammatory states, such as inflammatory bowel disease. Portal hypertension has not yet been studied as a risk factor for low IGF-1.

Methods: Children ages 3 months to 18 years with chronic liver disease were enrolled from an ambulatory clinic at a single center. Patients with comorbidities affecting intestinal inflammation or the growth hormone axis were excluded. Clinical data, nutritional assessmen, and serum samples for IGF-1 were obtained at enrollment. Patients were categorized by the presence or absence of portal hypertension using published criteria for CEPH. IGF-1 Z scores were analyzed as both continuous and dichotomous variable with low IGF-1 defined as Z score < -2. Low mid upper arm circumference (MUAC) was defined as Z score <-1. For children >5 years, both child and guardian completed the PedsQL Multidimensional Fatigue Scale (PedsQL MF) and were compared with a published cohort of 157 healthy children.

Results: 27 patients with median age 12.2 years were enrolled with the most common diagnoses being autoimmune hepatitis/primary sclerosing cholangitis and biliary atresia. 37% (n=10) patients had CEPH. The median IGF-1 Z score was -1.5. Children with CEPH had lower IGF-1 compared to patients without CEPH (p .003). Median height and weight Z scores in our cohort were close to 0 and when tested linearly, had no association with IGF-1. Low MUAC was associated with low IGF-1 (p .036). Median PedsQL MF scores from child and parent proxy were 63.89 and 75.70 respectively. Both were significantly lower compared to healthy children. Low IGF-1 levels were significantly associated with child reported fatigue (p .028).

Conclusions: Children with CEPH have low IGF-1 even in this population of stable patients with preserved linear growth. Lower IGF-1 Z scores are associated with an increased burden of child reported fatigue. Next steps will include measurement of serum cytokines and evaluation of the relationship between a pro-inflammatory state and IGF-1 Z scores.

Abstract# 1179

Hepatoportoenterostomy versus Primary Liver Transplantation for Biliary Atresia: A Review of the National Experience

D. Yoeli[1], R. A. Choudhury[1], S. S. Sundaram[2], C. L. Mack[2], J. P. Roach[3], F. M. Karrer[4], M. E. Wachs[1], M. A. Adams[1], *[1]Transplant Surgery, University of Colorado and Children's Hospital Colorado, Aurora, CO, [2]Pediatric Gastroenterology, Hepatology and Nutrition, University of Colorado and Children's Hospital Colorado, Aurora, CO, [3]Pediatric Surgery, University of Colorado, Aurora, CO, [4]Pediatric Surgery, University of Colorado and Children's Hospital Colorado, Aurora, CO*

Purpose: Kasai hepatoportoenterostomy (HPE) followed by liver transplantation (LT) if needed is the standard of care for children with biliary atresia (BA). Some, however, have advocated for primary liver transplantation (pLT) as a superior treatment approach. The aim of this study was to characterize the rate of pLT in the treatment of BA and compare outcomes of pediatric candidates with BA listed for liver transplantation with and without prior HPE using the national Scientific Registry of Transplant Recipients (SRTR)/Organ Procurement and Transplantation (OPTN) database.

Methods: The SRTR/OPTN database was retrospectively reviewed for all children with BA listed for primary liver transplant between March 2002 and December 2017. Candidates were categorized as pLT if they had not undergone previous abdominal surgery prior to listing. A multivariable Cox regression was performed to determine risk for waiting list mortality and post-transplant graft survival.

Results: 3,006 patients with BA were listed for LT during the study period. Only 11% of these candidates had not undergone previous abdominal surgery. Candidates without prior abdominal surgery were younger, smaller, had higher calculated PELD/MELD scores, and were more commonly female, non-White, and without private insurance. Candidates without prior abdominal surgery had higher risk for waiting list mortality (adjusted HR 0.53, 95% CI 0.34 - 0.84, p = 0.007). Among those that successfully underwent LT, there was no significant difference in graft survival by prior surgery status (p = 0.6).

Conclusions: Liver transplant candidates with BA initially treated with HPE had lower risk of death on the waiting list. HPE should remain the gold standard of care for children with BA, followed by LT if needed for progressive disease.

Abstract# 1180

Impact of Pediatric Living Donor Liver Transplant Center Volume on Waiting List and Post-Transplant Outcomes

D. Yoeli, R. A. Choudhury, H. B. Moore, T. L. Nydam, M. E. Wachs, E. A. Pomfret, M. A. Adams, *Transplant Surgery, University of Colorado School of Medicine and Children's Hospital Colorado, Aurora, CO*

Purpose: The aim of this study was to compare pediatric liver transplant (pLT) waiting list and post-transplant outcomes by center pediatric living donor liver transplant (pLDLT) volume.

Methods: The UNOS database was retrospectively reviewed for all children listed for pLT from March 2002 through December 2017. High pLT volume was defined as ≥ 100, medium volume as 10 - 99, and low volume as < 10 pLT during the study period. High LDLT volume was defined as ≥ 10, low LDLT volume as 1-9, and no LDLT as zero LDLT performed during the study period.

Results: 9,767 pediatric candidates were listed for pLT and 7,136 pLT were performed during the study period, with 928 (13%) pLDLT. 26 centers were high, 37 were medium, and 40 low pLT volume. 23 centers were high pLDLT volume, 33 were low pLDLT volume, and 47 performed no pLDLT. 17 of the 26 (65%) high pLT volume centers were also high pLDLT volume. Upon multivariable Cox regression, high pLDLT volume was significantly protective against waiting list mortality, independent of center pLT volume (adjusted HR 0.78, 95%CI 0.63 - 0.96, p = 0.02). Post-pLT recipient and graft survival was significantly greater at high pLDLT volume centers in comparison to centers with low and no pLDLT volumes (**Figures 1 & 2**).

Conclusions: Pediatric transplant centers with high living donor liver transplants volumes achieve superior waiting list and post-transplant survival outcomes, independent of overall pediatric liver transplant volume.

Figure 1. Recipient survival by pLDLT center volume (p < 0.001)

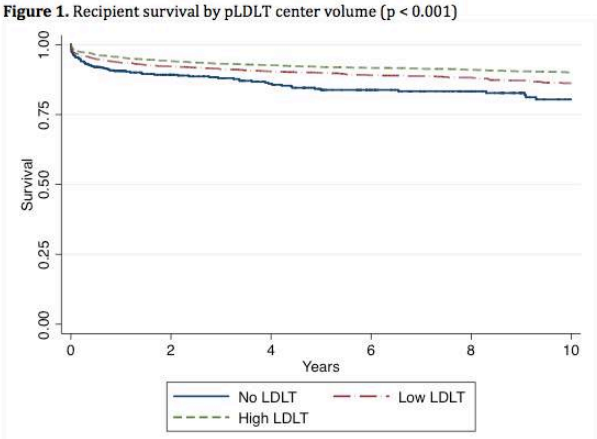

Figure 2. Graft survival by pLDLT center volume (p < 0.001)

Abstract# LB 88

Intestinal Insufficiency May Affect Outcomes After Pediatric Liver Transplantation

A. K. Batra, M. Desai, J. Yang, K. Cummins, H. Oden-Brunson, H. Ling, S. Beer, J. Goss, N. Galvan, *Surgery, Baylor College of Medicine, Houston, TX*

Purpose: The purpose of this study is to determine if pre-transplant feeding intolerance is associated with poorer post-OLT (orthotopic liver transplant) outcomes in pediatric liver transplant recipients, in the setting of limited published literature on the relationship between intestinal integrity and liver transplant outcomes.

Methods: A retrospective cohort study was performed on 248 pediatric patients who received orthotopic liver transplants between 2012 and 2019. 59 variables were collected which included lab values and perioperative complications such as thrombotic events, post-transplant infection, repeat laparotomy, ascites, gastrointestinal bleed (GI), and renal support. Patients were then categorized into feeding tolerant (n=154, n=171 pre- and post-op, respectively) or intolerant (n=94, n=77 pre-op and post-op, respectively) groups, based on several factors including their tolerance of feeds by mouth, tube feeds, or total parental nutrition. Chi-square tests were used to analyze the association between pre-transplant feeding intolerance and each of the outcome variables. Kaplan-Meier survival curves demonstrated 99% and 97% survival at 1 and 6 years in the feeding tolerant group, respectively, and 86% and 79% survival in the feeding intolerant group at 1 and 6 years, respectively.

Results: Bivariate analysis showed that pre-transplant feeding intolerance was significantly associated with post-transplant feeding intolerance, hepatic artery thrombosis, portal vein thrombosis, renal support, prolonged intubation, post-transplant infection, ascites, GI bleed, mortality, at a significance level of .05 for each. Variables that were assessed for association but were not found to be significantly associated include repeat laparotomy and ileus.

Conclusions: The results showed that pre-transplant feeding intolerance is associated with multiple post-transplant abdominal complications such as mortality and post-transplant infection. The implications of this highlights the importance of intestinal integrity reflected as feeding tolerance as a guide to perioperative risk stratification and care.

Liver: Large Data and Artificial Intelligence

Abstract# 1181

Application of Linear Discriminant Analysis (lda) to Differentiate Acute Rejection (ar) and Acute Dysfunction Non-Rejection (adnr) in Liver Transplant Recipients

M. Miller[1], R. Sinha[1], J. Weems[1], J. Holman[2], M. Altrich[1], S. Kleiboeker[1], J. Levitsky[3], *[1]R&D, Viracor-Eurofins, Lee's Summit, MO, [2]Transplant Genomics, Mansfield, MA, [3]R&D, Northwestern University Feinberg School of Medicine, Chicago, IL*

Purpose: Blood-based biomarkers distinguishing acute-rejection (AR) from other causes of graft dysfunction (acute dysfunction non-rejection (ADNR)) would have significant clinical applicability in liver transplant (LT) management. However, the high dimensionality of omics data, scarcity of clinical samples and individual diversity in gene expression levels decreases our power to detect disease-specific biomarkers. A logical first step to address these aforesaid issues is performing dimension-reduction and projection of data into a lower dimension space (2D or 3D), reflecting natural clustering of same-class samples. In our work we developed a Linear Discriminant Analysis (LDA) based classifier to differentiate AR and ADNR, using blood gene expression levels in LT patients.

Methods: A commonly used unsupervised technique (PCA), only works when interclass variance is higher than intraclass variance. In our work we used a supervised technique (LDA), which projects data into a lower dimension space and facilitates

grouping of same-category data points. We obtained the gene expression data of 91LT recipients (43 AR, 48 ADNR), from two previously published studies (CTOT14 and Northwestern University biorepository); and a symmetrical uncertainty filter was applied prior to LDA to remove highly correlated probes that destabilize the model. Transcriptome profiles based on whole blood samples were time-matched with biopsy results, whose phenotypes were directly determined from these studies.
Results: We found that supervised methods outperformed unsupervised techniques in our heterogeneous human clinical data. Subsequently, we developed an LDA based classifier to classify AR and ADNR cases in LT recipients with graft dysfunction. The classifier had overall accuracy in the training set of 83.5% (76/91) in leave-one-out cross-validation. Sensitivity was 93.0% (40/43) and specificity was 75.0% (36/48); PPV was 76.9% (40/52), and NPV was 92.4% (36/39).
Conclusions: Our work resulted in a highly accurate classifier to distinguish AR and ADNR; with clinical applications in allowing for non-invasive detection and treatment of AR with higher certainty and safety than current clinical tools.

Abstract# 1182

Artificial Neural Network Application for MELDNa Prediction

L. Pruinelli[1], M. Nguyen[1], S. Olson[1], J. Zhou[1], J. Schold[2], T. Pruett[1], S. Ma[1], G. Simon[1], *[1]University of Minnesota, Minneapolis, MN, [2]Cleveland Clinic Foundation, Cleveland, OH*
Purpose: The adoption of MELDNa decreased 90-days mortality on patients waiting for liver transplant (LT); however, there are no tools available to predict MELDNa trajectories progression over time. We aim to predict MELDNa for patients at any time on the waiting list based on previous scores; thus, providing additional resources for transplant centers and organ reallocation and provide patients' estimated MELDNa progression. A stacked Long Short-Term Memory (LSTM) was applied to predict the next MELDNa for individual patients.
Methods: A retrospective cohort of patients who underwent LT from 2006 and 2019 was derived from UMN Clinical Data Repository that includes electronic health records from the M Health Fairview. Data includes demographic, medical diagnoses, billed procedures, laboratory results, medications, notes, and flowsheet measures for >2.5 million patients. Cohort selection, data preparation steps, and modeling is shown in the figure below. We build the model by stacking 2 layers of LSTM models. The model' parameters are optimized using Keras Tuner, and performance measured using R^2 and *MSE*. Data management and analysis was performed inside the Minnesota Super Computing using Python 3.0.
Results: The LSTM model has R^2 of 0.64 and *MSE* of 0.03 suggesting current and previous MELDNa scores are able to explain 64% the next MELDNa at a certain point time, with an error between expected and predicted of 3%. Applying LSTM to a given MELDNa of a cohort of patients, we can use the past 6 days MELDNa to predict future 3 days MELDNa scores with reliable accuracy.
Conclusions: In this model, we use optimized numbers to demo model performance and show the potential for MELDNa prediction while on the waiting list. The number of past data points and future data points could be optimized for maximum model performance or pre-selected, depending on practical demands. In the near future, based on the current state (including other factors, such as health status, comorbidities) of the patient, we will be able to optimize a model in a way that can predict how much MELDNa will change and how fast the change will take place with high accuracy. A model able to predict MELDNa over time could influence waiting list management, organ allocation and patient engagement into their own care, while estimating resources allocation and care delivery.

Abstract# LB 84

Deep Learning Based Automatic Liver Volume Estimation and Segmentation via U-net Convolutional Neural Network

B. Marlatt[1], R. Pettit[2], J. Havelka[1], S. J. Corr[3], A. Rana[2], *[1]InformAI, Houston, TX, [2]Baylor College of Medicine, Houston, TX, [3]Houston Methodist, Houston, TX*
Purpose: To create a deep learning model to accurately perform abdominal organ segmentation and volumetric measurements on existing donor and recipient imaging for size matching.
Methods: The U-Net deep learning image processing algorithm has previously demonstrated success at accurately sectioning out relevant features from standardized medical images. We implemented this method to identify the borders of livers used in solid organ transplantation. Using publicly available CT DICOM scan images from the Liver Tumor Segmentation Challenge (2017) and the 3D Image Reconstruction for Comparison of Algorithm Database (2015) consortiums, we accessed and harmonized 151 abdominal computed tomography scans. For each 3D CT scan, a board-certified radiologist had previously annotated the margins of the liver within the abdominal cavity. We split these data into 64% training, 16% validation, and 20% test sets. After training our U-Net system on these data, we measured the accuracy with which the model identified livers using a Sørenson-Dice coefficient, which measures degree of overlap between predictions and the ground truth. After identifying the borders of the liver with U-Net in 3-dimensional voxels, we multiplied the summed voxels contained in the liver by the X and Y dimensions as well as the CT slice thickness to reconstruct a full organ volume estimate.
Results: The U-Net model was trained against the Radiologist sectioned CT liver images contained in the training and validation datasets and performance of the model was evaluated against the test dataset. The U-Net model was able to accurately identify the border of the liver with a Dice coefficient of 0.968 in the validation set. The Dice coefficient represents the degree of predicted versus observed overlap and can be interpreted as a 96.8% overlap accuracy. Our calculated volume estimates differed from the Radiologist identified standard liver tracings with a percent error of 4.54% $\pm$ a standard deviation of 4.49% when testing on the test set.
Conclusions: Precise volume estimation of livers from CT scans is accurate using a U-Net deep learning architecture. Appropriately deployed, a U-Net algorithm is precise and quick, making it suitable for incorporation into the pre-transplant clinician decision making workflow. Side by side recipient and donor volumetric measurements can greatly facilitate size matching and prevent inefficiencies in organ allocation and reduce discard. This is especially important in pediatric populations where size matching can be difficult to estimate.

Abstract# 1195

BK Virus-associated Nephropathy as a Cause of Renal Failure Post-lung Transplantation

A. Arjuna, M. T. Olson, B. Buddhdev, R. Tenorio, A. Omar, S. Tokman, *Norton Thoracic Institute, St. Joseph's Hospital and Medical Center, Phoenix, AZ*

Purpose: BK virus-associated nephropathy (BKVAN) is a common cause of renal dysfunction early after renal transplant. BKVAN is much rarer in non-renal solid organ transplant, where data regarding diagnosis and management is limited. We present 2 cases of renal failure secondary to biopsy-proven BKVAN in lung transplant recipients.

Methods: We reviewed the infectious courses of BK viremia in two bilateral lung transplant recipients from our center: a 59-year-old female transplanted in July 2019 (patient A), and a 76-year-old female transplanted in September 2016 (patient B), both secondary to IPF.

Results: Patient A had an uneventful early postoperative course with preserved renal function (baseline serum creatinine: 0.98 mg/dL) up to 5 months post-transplant while receiving tacrolimus for maintenance immunosuppression and trimethoprim-sulfamethoxazole for *Pneumocystis* pneumonia prophylaxis. At 5 months, an acute rise in serum creatinine (1.42 mg/dL) was observed and attributed to her medication regimen. Despite altering her medications, serum creatinine continued to rise (2.52-3.21 mg/dL). Investigation for infectious causes revealed elevated BK viral loads in plasma (260,000 copies/mL), prompting a renal biopsy which demonstrated tubules staining positive for BK virus with tubulointerstitial fibrosis - consistent with BK-VAN. Leflunomide was initiated with gradual viral clearance. Her serum creatinine has since trended down (2.26 mg/dL), but remains elevated from baseline. Patient B also had an uneventful postoperative course, with stable allograft function through 3 years post-transplant. At 38 months, she was admitted for decline in lung function secondary to *Nocardia* infection requiring prolonged hospital stay. Gradual rise in serum creatinine was observed over the course of the next two months (baseline: 1.6 mg/dL), attributed to medications. Despite altering her regimen, serum creatinine continued to rise (2.34-3.10 mg/dL), prompting investigation that revealed BK viremia (39,000 copies/mL). Renal biopsy findings were consistent with BKVAN, and leflunomide was initiated with gradual viral clearance; serum creatinine remains elevated (2.7 mg/dL) from baseline.

Conclusions: BKVAN can lead to irreversible kidney injury in lung transplant recipients despite reduction in immunosuppression, leflunomide therapy, and reduction in viral load.

Abstract# 1196

Antibody-mediated Rejection and Sponge Effect in a Redo Lung Transplant Recipient: A Case Report

A. Arjuna, M. T. Olson, S. Tokman, R. Walia, T. Mohanakumar, A. S. Hashimi, M. A. Smith, R. M. Bremner, A. Omar, *Norton Thoracic Institute, St. Joseph's Hospital and Medical Center, Phoenix, AZ*

Purpose: Antibody-mediated rejection (AMR) typically presents with elevated titers of circulating donor specific antibodies (DSA) and increased mean fluorescence intensity (MFI), a surrogate marker for antibody titers. However, patients with AMR may rarely have scant DSAs in circulation partly due to the "sponge effect" related to DSAs binding to human leukocyte antigen (HLA) molecules within the lung.

Methods: We report the case of an 18-year-old female lung transplant recipient with cystic fibrosis who ultimately required retransplantation and developed circulating DSA directed toward the first allograft, but detected in circulation only after retransplantation.

Results: Figure 1 depicts the MFI of post-transplant DSA to donor HLA. Two months after primary transplant, the patient developed de novo-DSA requiring monthly intravenous immunoglobulin infusions. Pulmonary function remained otherwise stable through the first post-transplant year, but declined insidiously over the following few months. At 19 months post-transplant, she was admitted for acute hypoxemic respiratory failure, necessitating prolonged hospital stay. Redo bilateral lung transplant was performed at 23 months from the primary operation. Following retransplant, serum DSA analysis showed persistent DSAs to mismatched HLA of both the first and second donor allograft. She was treated for probable AMR, and despite aggressive intervention, succumbed to RAS phenotype CLAD.

Conclusions: The present case draws attention to a rare finding of sponge effect in a patient with AMR leading to allograft failure. We conclude that the absence of circulating DSAs does not rule out AMR. We also postulate that circulating DSAs directed toward a first allograft may drive AMR after retransplant due to cross-reactive epitopes.

Abstract# 1197

Impact of Positive Donor Cultures on Postoperative Lung Transplantation Infectious Outcomes

A. Curtis, C. Pham, B. P. Pierce, *Houston Methodist Hospital, Houston, TX*

Purpose: Transmission risk of microbes present in donor lungs at time of donation to lung transplant recipients (LTR) is unclear. Infection is the second highest cause of 30-day (d) mortality, and the first between 30d-1 year after lung transplant (LT). Guidelines for donor derived infections in transplant recommend 7-14d of antibiotics (ABX) in recipients of bacteremic donors. There are limited data assessing transmission of non-blood donor infections and outcomes post-LT.

Methods: We reviewed LTR from 2016-2020 with positive donor cultures from any culture site. Patients were excluded if they had cystic fibrosis, a multiorgan or redo LT, or active infection at time of LT. Protocol post-op ABX included vancomycin and cefepime x7d with extension to 14d if positive donor cultures were reported. Our primary outcome was incidence of *C. difficile* (*C. diff*) and infections due to multi-drug resistant organisms (MDRO) within 90d post-LT. Secondary outcomes included *C. diff* and MDRO by 30d, characterization of transmissions, length of stay, ABX regimens, and 90d mortality.

Results: Of 83 included patients, *C. diff* and MDRO each occurred in 11% (n=9) of LTR within 90d. Donor cultures were 96% bacterial and 94% were derived from lungs/sputum. Immediate organism clearance (organism identified in donor culture but not found in LTR cultures) occurred in 83% of LTR (n=69). Of the donor-derived organisms from the 14 LTR that grew through post-op ABX, all were bacteria and isolated to respiratory infections (RI); *S. aureus* accounted for 71% of detected organisms. No RIs progressed to bacteremia. There were no cases of *C. diff* and 4 cases of MDRO in these positive RI LTR; 2 MDRO were donor-derived. Median duration of post-op ABX was 14d (IQR 11-18) in these positive RI LTR vs 11d (IQR 9-15) in those who demonstrated immediate clearance. Positive RI LTR demonstrated organism clearance after a median of 4d (IQR 3-6). No donor urinary tract or bloodstream infections were transmitted.

Conclusions: While incidence of *C. diff* and MDRO within 90d was low and did not appear to be correlated with ABX duration, LTR may still benefit from decreased ABX duration given immediate clearance did occur in 83% of LTR. Because LTR with donor-derived organisms were able to clear them by 4d, an extended duration of ABX may not be necessary. High rates of *S. aureus* detection may be due to donor colonization presenting as positive assays without apparent disease, and did not appear to affect post-LT outcomes. Our study suggests that extended ABX past 7d may not be necessary in LT patients with gram (+) respiratory cultures or in LT patients with non-respiratory and/or non-bacteremic donor cultures.

Abstract# 1198

Long-Term Renal Outcomes in Lung Transplant Recipients- A Single-Center Five-Year Experience

M. Doraiswamy, E. Obole, P. Singh, T. Pesavento, *Comprehensive Transplant Center, The Ohio State University Wexner Medical Center, Columbus, OH*

Purpose: The increased longevity in Lung transplant (LTx) has led to an upsurge in chronic medical comorbidities, including Acute kidney injury (AKI), Chronic kidney disease (CKD) and End stage renal disease (ESRD). Our research aims to understand the magnitude of the AKI/CKD problem in LTx recipients and its long-term implications over five years.
Methods: We conducted a retrospective chart review of 171 adults with LTx from January 2014 to January 2019 with a follow-up of at least six months. Primary outcomes were prevalence of CKD/ESRD, AKI as a risk factor for CKD, length of stay [LOS] during index hospitalization and association of CKD with cardiovascular morbidity, and all-cause mortality.
Results: A total of 171, 161, 153, 47, and 12 recipients formed the cohort at baseline, six, 12, 36, and 60 months, respectively. Baseline median creatinine was 0.8mg/dL, and eGFR was 90 mL/min/1.73m2. The odds of CKD development in patients with an AKI during index hospitalization versus no AKI was 6.22 [2.87 to 13.06, p-value < 0.0001]. Patients with AKI during index hospitalization had an increased length of hospital stay. The mean difference in length of stay in patients with AKI compared to no AKI was 15.8 +/- 6.6, p-value < 0.0001. The difference between mean tacrolimus trough between AKI and non-AKI was 1.064, but it was not statistically significant (p-value = 0.067). The supratherapeutic tacrolimus levels are an important cause of AKI but might not be the only etiology, and thus the results should be interpreted with caution. The eGFR drastically decreased from transplant, and 94%, 40%, 33%, 21%, and 14% had an eGFR of > 60 mL/min/1.73m2 at baseline, 6, 12, 36, and 60 months, respectively. By six months, 60% [96 out of 161] patients were labeled as CKD, which rose to 86% [10 out of 12] at 60 months. 19% required Renal replacement therapy (16% dialysis and 3% Kidney transplant) by the end of the study. The median number of dialysis treatment was five during index hospitalization but was as high as 203. The odds ratio of all causes mortality in patients with CKD compared to non-CKD was 3.36 [1.44 to 8.64, p-value = 0.005]. In our cohort, 43% of patients have a baseline history of Cardiovascular disease (CVD), and 25% developed new-onset CVD during five years of follow-up. However, there were no increased odds to develop CVD in patients based on CKD [odds ratio 1.2, p-value = 0.63]. Only 15% of CKD patients were being followed by outpatient nephrologists. The diagnostic modalities of CKD like Urinalysis, Urine protein creatinine ratio, renal biopsy, and imaging were poorly utilized.
Conclusions: Our study is the first to evaluate the prevalence and long-term complications associated with CKD post-Lung transplant over a five-year follow-up period. Basic/translational studies to delineate the mechanism of development of CKD and large prospective trials to understand the long-term effect on Lung transplant recipients are warranted.

Abstract# 1199

A Case-Match Cohort Comparison of the Safety and Efficacy of Basiliximab for Immunosuppression Holiday in Lung Transplant Patients

M. M. Eiting[1], J. E. Clark[1], T. L. Astor[2], J. Palafox[2], C. Rogers Marks[1], G. Waldman[1], *[1]Pharmacy, Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, MA*

Purpose: Post-transplant complications related to calcineurin inhibitors (CNI) maintenance immunosuppression (MI) may require interim alternative therapies. The goal of this study is to evaluate the safety and efficacy of basiliximab (BAS) when CNI MI is held due to adverse effects (AEs) including renal (RT) and hematologic toxicity (HT) compared to a case-match cohort.
Methods: This was a retrospective single-center case-match (CM) analysis of lung transplant recipients (LTR) hospitalized between January 2016 and July 2020, found to have CNI related AEs, comparing LTRs receiving BAS for CNI holiday to those who did not. The primary endpoint was rejection free survival (biopsy-proven or presumed rejection) at 6 months post-intervention for toxicity. Additional endpoints include recovery from CNI toxicity, infection, and progression to bronchiolitis obliterans syndrome (BOS). Toxicity analysis was expressed as degree of recovery.
Results: Forty-four LTRs were included and are described in Table 1. Baseline characteristics were not statistically different. Of LTRs, the BAS group experienced lower rejection free survival (64 % vs 91%) at 6 months, compared to the CM group (p=0.042; Figure 1). The BAS group experienced more infections at 6 months compared to the case-match group (95% vs 82%).
Conclusions: BAS therapy as an interim CNI holiday may lead to improved long-term toxicity recovery, however an increased risk of rejection must be weighed against these benefits.

Abstract# 1200

Therapeutic Enoxaparin Dosing in Lung Transplant Recipients

S. Finder, M. Morrison, K. B. Harrison, S. A. Heeney, *Vanderbilt University Medical Center, Nashville, TN*

Purpose: Enoxaparin 1 mg/kg subcutaneously every 12 hours for therapeutic anticoagulation is known to increase rates of supratherapeutic anti-Xa levels in lung transplant recipients (LTRs). Since enoxaparin is renally eliminated, this risk may be higher in patients with renal impairment. Our protocol uses enoxaparin 0.8 mg/kg every 12 hours in LTRs. This study aims to evaluate anti-Xa levels using the current protocol and whether these levels are impacted by renal function.

Methods: This single center, retrospective analysis included LTRs from 11/2017-8/2020 who received therapeutic enoxaparin with an anti-Xa level (drawn 3-6 hours post-injection after ≥3 doses). Therapeutic anti-Xa levels were defined as 0.6-1.0 IU/mL. LTRs with creatinine clearance (CrCl) <30 mL/min were excluded. The primary outcome was incidence of therapeutic anti-Xa levels in the cohort. The secondary outcome was incidence of therapeutic anti-Xa levels based on renal function, with renal dysfunction defined as CrCl <60 mL/min.

Results: Of 109 LTRs, 29 were included. The study cohort was median 62[56-66] years old, 78.9[67.1-86.7] kg, 65.5% male, and 48.3% received a double lung transplant. Indications for anticoagulation were venous thromboembolism (79.3%) and atrial fibrillation (20.7%). Twelve (41.4%) had CrCl <60 mL/min. Overall, the mean anti-Xa was 0.85±0.36 IU/mL, with 41.3%, 20.7%, and 37.9% in a therapeutic, subtherapeutic, and supratherapeutic range, respectively. The mean dose among LTRs with and without renal dysfunction was similar (p=0.86), however, the mean anti-Xa in the renal dysfunction group was significantly higher (p=0.005, Table). LTRs with renal dysfunction were more likely to have an anti-Xa in the supratherapeutic range (Figure).

Conclusions: A majority of LTRs did not achieve therapeutic anti-Xa levels on enoxaparin 0.8 mg/kg every 12 hours. This may be attributed to the high incidence of supratherapeutic anti-Xa levels among LTRs with renal dysfunction. A dose reduction in this population may be warranted. Further research is needed to determine the optimal enoxaparin dose in LTRs with renal impairment.

Enoxaparin dosing based on renal function			
	CrCl ≥60 mL/min (n=17)	CrCl <60 mL/min (n=12)	P value
Dose, mg/kg (mean ± SD)	0.78 ± 0.07	0.75 ± 0.11	0.86
Anti-Xa, IU/mL (mean ± SD)	0.70 ± 0.29	1.08 ± 0.34	0.005

Abstract# 1201

Lung Transplant Outcomes Based on Immunosuppressive Regimen at Discharge: Data from the US Scientific Registry of Transplant Recipients (SRTR)

W. Fitzsimmons[1], J. Erdman[2], J. Wolfram[3], D. Nimke[2], R. Croy[2], X. Wang[2], T. Weaver[4], D. Schladt[4], *[1]University of Illinois at Chicago, College of Pharmacy, Vernon Hills, IL, [2]Astellas Pharma, Inc, Northbrook, IL, [3]Astellas Pharma Europe BV, Leiden, Netherlands, [4]Chronic Disease Research Group, Minneapolis, MN*

Purpose: There is currently no FDA approved immunosuppressive regimen for lung transplant (Tx) recipients; however, patients routinely receive a calcineurin inhibitor-based regimen. The SRTR database was analyzed to provide real-world evidence of the efficacy and safety of tacrolimus-based immunosuppressive regimens post lung Tx.

Methods: Adult and pediatric recipients of a primary deceased donor lung Tx between January 1, 1999 and December 31, 2017 were followed for 3 years post Tx based on immunosuppressive regimen at discharge: immediate-release tacrolimus+mycophenolate mofetil (MMF), immediate-release tacrolimus+azathioprine (AZA), cyclosporine (CYA)+MMF, or CYA+AZA. The primary outcome was the composite endpoint of graft failure or death (all cause) at 1 year post Tx. Cox proportional hazard models were used to test for baseline characteristics associated with a greater risk of graft failure or death in adults.

Results: Data were available for 26,080 lung Tx recipients (25,355 adults; 725 pediatrics). The most common discharge immunosuppressive regimen was immediate-release tacrolimus+MMF in both groups. Post-Tx outcomes are shown in Tables 1 (adults) and 2 (pediatrics). Adult and pediatric lung Tx patients receiving immediate-release tacrolimus+MMF had a cumulative incidence of graft failure or death at 1 year post Tx of <9% (graft survival >91%) and the lowest rejection rates at 3 years, without increased risk of infection or malignancy. Factors associated with a greater risk of graft failure or death in adults receiving immediate-release tacrolimus+MMF included: recipient age ≥65 years, single lung Tx, hospital stay >24 days, BMI <18.5 kg/m^2, serum creatinine ≥1.0 mg/dL, donor age ≥55 years and donor race (Black). Factors associated with a lower risk of graft failure or death included: age at Tx 35-49 years, recipient race (Black), post-Tx hospital stay ≤14 days and CMV-negative donors. The risk of graft failure or death was significantly greater in adults receiving CYA+MMF or CYA+AZA compared with immediate-release tacrolimus+MMF.

Conclusions: Use of immediate-release tacrolimus+MMF as the discharge immunosuppressive regimen in lung transplant recipients increased substantially from 1999-2017, and was associated with higher 1-year graft survival and numerically lower rates of rejection at 3 years versus CYA+MMF and CYA+AZA.

Abstract# 1202

Textbook Outcome: A Novel Metric in Lung Transplantation Outcomes

A. M. Ganapathi[1], B. A. Whitson[1], N. A. Mokadam[1], B. C. Keller[2], A. Logan[1], G. Brock[1], K. Washburn[1], A. D. Schenk[1], *[1]Surgery, Ohio State University Wexner Medical Center, Columbus, OH, [2]Medicine, Ohio State University Wexner Medical Center, Columbus, OH*

Purpose: Lung transplant programs are typically assessed based on 1-/3-year survival, however other factors such as quality of life, freedom from rejection and oxygen, etc., are important factors to recipients and the health care system. Thus, we defined a "textbook outcome" (TO) for lung transplant recipients as one without major complication as an ideal post-transplant course, and examined the association with long-term survival.

Methods: All primary, adult lung transplants from 5/1/05-12/31/17 were identified with the SRTR dataset. TO was defined as absence of mortality, retransplant, graft failure, dialysis, treated rejection in the 1st year, length of stay <31 days, and no airway dehiscence, post-transplant stroke, or use of oxygen at 1-year, and forced ejection volume at 1 second (FEV1) greater than the 50% predicted at 1 year. Recipient and transplant characteristics were analyzed. Kaplan-Meier analysis with the log-rank test examined long term survival for patients surviving >1 year (conditional survival).

Results: 14,842 patients were identified and 7,319 (49.3%) had a TO. Patients not achieving a TO typically failed to satisfy 2 or more criteria. Characteristics that were significantly associated with TO included white race, not being hospitalized prior to transplant, decreased median ischemic time, or diagnosis of obstructive disease or cystic fibrosis (p<0.01; Table). At 1 year the FEV1 was greater in patients who achieved a TO (81% Predicted) as compared to those who did not (64% Predicted). Conditional survival analysis revealed significantly increased survival at 5 years in patients who achieve TO (p<0.01; Figure).

Conclusions: Textbook outcome is a novel means of examining patient outcomes in lung transplantation and adds further meaning to short term survival, the current standard of success. Given the association of TO with increased long-term survival and an improved FEV1 at 1-year, patients achieving a TO appear to have an increased quantity and potentially quality of life. Further examination and validation of this metric is warranted.

Abstract# 1204

Lung Transplantation After Ex-Vivo Lung Perfusion versus Static Cold Storage: A Single Institution Cost Analysis

S. E. Halpern[1], S. J. Kesseli[2], S. Au[1], M. K. Krischak[1], D. G. Olaso[1], H. Smith[3], G. Tipton[2], I. Jamieson[3], J. C. Haney[2], J. A. Klapper[2], M. G. Hartwig[2], *[1]Duke University School of Medicine, Durham, NC, [2]Surgery, Duke University Medical Center, Durham, NC, [3]Office of Finance, Duke Transplant Center, Durham, NC*

Purpose: Ex-vivo lung perfusion (EVLP) allows for reconditioning of "marginal" lung grafts and extended lung preservation. However, EVLP is costlier than cold storage. We compared perioperative outcomes and index hospitalization costs among matched EVLP and non-EVLP lung transplant (LTx) recipients to explore whether upfront device costs may be offset by reduced postoperative costs.

Methods: LTx recipients at our institution who received donor lungs that underwent EVLP were eligible for inclusion. Patients without cost data were excluded. A group of non-EVLP bilateral LTx recipients was matched 1:3 (nearest neighbor) based on age at LTx, disease group, lung allocation score, and history of prior LTx. Perioperative outcomes and index hospitalization costs were compared between EVLP and non-EVLP groups using descriptive statistics.

Results: 22 EVLP and 66 non-EVLP LTx recipients were included. Total preservation time was median 840 vs 415 minutes for EVLP and non-EVLP lungs, respectively (p<0.01). Median EVLP time was 313 minutes. EVLP lungs had lower pre-procurement PaO_2/FiO_2 ratios than non-EVLP lungs (median 334 vs 444, p<0.01) and were more likely to come from DCD donors (27.3% vs 10.6%, p=0.056). Post-LTx ICU stays were longer among EVLP patients; other outcomes were similar between groups (**Table**). Excluding device-specific costs, direct variable and total index hospitalization costs were higher among EVLP vs non-EVLP patients (direct variable: median $200,404 vs $157,852, p=0.047; total: median $336,290 vs $271,306, p=0.03) (**Figure**). EVLP patients incurred higher inpatient pharmacy and diagnostic testing costs than non-EVLP patients, the latter mostly representing bronchoscopies.

Conclusions: In this institutional analysis, EVLP LTx recipients incurred higher index hospitalization costs than non-EVLP LTx recipients. Further investigation is needed to better understand financial implications of EVLP as a facilitator of donor pool expansion and improved logistics in an era of broader lung sharing.

Table. Post-transplant perioperative outcomes stratified by use of ex-vivo lung perfusion.			
Characteristic	Static Cold Storage N = 66	Ex-Vivo Lung Perfusion N = 22	P-value
Reintervention within 30 days	10 (15.2%)	5 (22.7%)	0.4

Abstract# 1205

Pre-Procurement Cardiac Arrest in Lung Allograft Donors and Effects on Recipient Outcomes

T. J. Hathaway, E. C. Klipsch, D. Roe, C. Hage, M. Duncan, R. S. Mangus, *Indiana University School of Medicine, Indianapolis, IN*

Purpose: This study seeks to help expand the lung transplant donor pool by demonstrating the safe use of lung allografts from donors who underwent pre-procurement cardiac arrest (PPCA) in the hopes of lowering the high waitlist mortality in lung transplantation.
Methods: This study is a retrospective analysis of 278 lung transplant recipients at a single center from 2013 to 2018. Donor demographics, cause of death, and signs of early lung injury were determined by reviewing original medical records as well as records from the United Network of Organ Sharing. Recipient hospital records were extracted to review recipient demographics and clinical outcomes.
Results: Of the 278 lung transplant recipients included in this study, 120 received lung allografts from donors who experienced PPCA. Donors who underwent PPCA were more likely to have a history of tobacco abuse ($p = 0.001$) and were more likely to be smoking at the time of procurement ($p = 0.007$). There were no significant differences in recipient demographics or intraoperative variables between the two groups. In regard to short-term clinical outcomes, the PPCA group demonstrated shorter median time spent on mechanical ventilation ($p < 0.01$), shorter initial hospital stays ($p = 0.05$), lower rates of postoperative tracheostomy ($p < 0.01$), and a lower chance to be on extracorporeal membrane oxygenation for greater than 48 hours ($p = 0.04$). When comparing the survival of the two groups, recipients with PPCA allografts had better survival at 1-year post-transplant ($p = 0.04$), but there was no significant difference in survival at 3-years ($p = 0.97$) and 5-years ($p = 0.64$). Additionally, Kaplan-Meier analysis showed no difference in mortality between the two groups ($p = 0.35$).
Conclusions: PPCA in the donor does not lead to worse clinical outcomes in lung transplant recipients. Select short-term clinical outcomes and 1-year survival were better in recipients of PPCA donor allografts, and long-term outcomes showed no significant difference between the two groups. Based on the results of this study, lung allografts from donors who suffered PPCA should not be regarded as inherently inferior as they can be used to provide equivalent clinical outcomes in recipients when compared to other donor allografts.

Abstract# 1206

Incidence and Risk Factors for Nonmelanoma Skin Cancer in Lung Transplant Recipients

G. Holdren[1], E. Lushin[1], M. Duncan[2], C. Hage[2], *[1]Pharmacy, Indiana University Health, Indianapolis, IN, [2]Pulmonary Critical Care, Indiana University Health, Indianapolis, IN*

Purpose: The purpose of this study is to identify the incidence of nonmelanoma skin cancer (NMSC) post lung transplantation and to examine the relationship between risk factors for NMSC and the time to development of NMSC post lung transplantation.
Methods: A retrospective, single center study of lung transplant recipients transplanted between 2000 and 2019 was conducted to compare patients with a diagnosis of NMSC post transplantation (NMSC group) to those that did not develop NMSC post transplantation (control group). Patients were excluded if <18 years, had a previous lung transplant, or received a multi-organ transplant. Continuous and categorical variables were compared using T-tests and Chi-squared tests.
Results: Of the 654 patients that met inclusion criteria (NMSC group=154), 614 were Caucasian, 332 were male, and the mean age at transplant was 57.7 ± 10.4 years. The most common indications for transplant were COPD/emphysema (n=302), IPF/UIP (n=254), and cystic fibrosis (n=47). The incidence of NMSC post lung transplant was 23.5% and the mean time to development of NMSC was 4.89 ± 3.71 years. Risk factors that correlated with development of NMSC included male gender (OR=1.61, p=0.011), Caucasian race (OR=13.8, p<0.001), rejection treatment with T-cell depleting agents (OR=2.08, p=0.001), and history of NMSC prior to transplant (OR=23.5, p<0.001). Cumulative days of exposure to maintenance immunosuppression and antifungal agents were also different between the NMSC and control groups for azathioprine (932 v. 290, p<0.001), mycophenolate (1625 v. 898, p<0.001), sirolimus (870 v. 272, p<0.001), tacrolimus (2429 v. 1296, p<0.001), and voriconazole (157 v. 88, p<0.001). Linear regression analyses were performed to assess the relationship between cumulative days of immunosuppression and the time to development of NMSC. Cumulative days of tacrolimus (569+0.002*[days], R^2=0.674, p<0.001), azathioprine (1456+0.002*[days], R^2=0.195, p<0.001), mycophenolate (1007+0.002*[days], R^2=0.449, p<0.001), and sirolimus (1507+0.002*[days], R^2=0.178, p<0.001) correlated with a faster onset of NMSC post transplantation.
Conclusions: We identified strong predictors for the development of NMSC in lung transplant recipients, as well as the time to development of NMSC. A risk prediction model for the development of NMSC in lung transplant recipients is currently under development based on this large cohort of patients.

Abstract# 1207

Postoperative Tracheostomy as a Predictor of Poor Clinical Outcomes in Lung Transplantation

E. C. Klipsch, T. J. Hathaway, D. Roe, C. Hage, M. Duncan, R. S. Mangus, *Indiana University School of Medicine, Indianapolis, IN*

Purpose: Tracheostomies are commonly performed postoperatively in lung transplant recipients to provide ventilation for prolonged periods, and with relatively few studies detailing these patients' outcomes and survival as compared to the general recipient population, this study seeks to determine if postoperative tracheostomy is a marker for worse clinical outcomes in lung transplant recipients.
Methods: This is a retrospective analysis of 278 lung transplant recipients at a single center from 2013 to 2018. The original medical records as recorded by the onsite coordinator were reviewed along with records from the United Network of Organ Sharing to determine donor demographics, cause of death, and any evidence of early lung injury. Recipient demographics and clinical outcomes were extracted from hospital records.
Results: Of the 278 patients included in this study, 42 underwent postoperative tracheostomy. Predictors of need for tracheostomy were higher lung allocation scores ($p < 0.001$), recipient hospitalization prior to transplant ($p <0.001$), and higher pre-transplant mean pulmonary artery pressures in recipients ($p = 0.001$). Additionally, patients who required a tracheostomy were more likely to have a delayed surgical closure of the chest ($p < 0.001$) and require over a liter of packed red blood cells intraoperatively ($p < 0.001$). In regard to short-term outcomes, they were more likely to require use of extracorporeal membrane oxygenation for greater than 48 hours ($p < 0.001$), spent longer time on the ventilator ($p < 0.001$), had longer hospital stays

($p < 0.001$), were more likely to require reintubation ($p < 0.001$), and had higher rates of atrial arrhythmias ($p < 0.001$). In comparison to the control group, the tracheostomy group had decreased survival rates at 1-year ($p < 0.001$) and 3-years ($p = 0.01$) but showed no significant difference at 5-years ($p = 0.22$). Kaplan-Meier analysis showed that recipients with postoperative tracheostomies had significantly higher mortality rates as compared to controls ($p = 0.01$).

Conclusions: In this cohort of patients, need for postoperative tracheostomy was associated with more critically-ill patients as well as difficult intraoperative courses. Patients requiring tracheostomy also experienced worse short-term outcomes and decreased survival for the first 3 years after transplant. This data suggests that postoperative tracheostomy could be a predictor of worse clinical outcomes after lung transplantation.

Abstract# 1208

Mortality from Fulminant Myocarditis in Multi-organ Transplant Recipient with Covid-19

K. Mahendraraj, I. Kim, T. Todo, T. Brennan, N. Nissen, K. Kosari, G. Voidonikolas, D. Ramzy, *Transplant Surgery, Cedars-Sinai Medical Center, Los Angeles, CA*

Purpose: Novel coronavirus infection has been rarely described in multi-organ transplantation. This case highlights the poor prognosis associated with cardiac involvement by SARS-Cov-2 in transplantation, despite resolution of respiratory infection.

Methods: Case report from retrospective chart review.

Results: The patient is a 48 year old woman with end stage lung and renal disease. In late 2019, the patient underwent a bilateral lung transplant and simultaneous kidney transplant. Postoperative period was noted for multiple readmissions for post-obstructive pneumonia. By early March 2020 she had made a good functional recovery. In late March the patient's husband, who worked as a ride-share driver, developed fevers and cough but continued working. Four days later, the patient developed fevers and a productive cough. This is considered her first day of COVID-19 symptoms. Subsequent days will be referred to as 'post-symptom days' (PSD#). She presented on PSD#4 with a fever of 102.8 F. The patient's COVID test was positive. During her five-day hospitalization, she remained afebrile, and she was weaned off oxygen. Echocardiogram was normal. She continued to do well clinically and was asymptomatic at discharge, with oxygen saturation of 100% on room air.

Two days later (PSD#10), the patient returned with hypoxia requiring intubation. She rapidly went into complete heart block, requiring CPR and cardioversion. Her previously normal LVEF was now 25%, with global hypokinesis. Acute phase reactant levels were markedly elevated. Lab-work indicated acute cardiac, liver and kidney injury, consistent with COVID-19-induced fulminant myocarditis and cardiogenic shock. CXR showed patchy bilateral infiltrates concerning for superimposed bacterial pneumonia. Through PSD#13, she required maximal doses of vasopressors. On PSD#14, we administered IV tocilizumab. She had mild clinical improvement. On PSD#16, she suddenly decompensated, developing atrial fibrillation. X-rays showed dilated loops of bowel with pneumatosis. An emergent bedside laparotomy was performed. Her entire small bowel and colon was ischemic, with extensive necrosis. Shortly after, the patient developed asystole and was pronounced dead.

Conclusions: Inflammatory or hypoxic disruption of myocardial pericytes in COVID-19 can result in microvascular dysfunction and cardiac ischemia which can precipitate heart failure. In the setting of a cytokine storm, this can lead to profound systemic shock and multisystem organ failure, with potentially fatal consequences in transplant recipients.

Creating a Lung Transplant Program Search Tool Tailored to Patient Characteristics

W. T. McKinney[1], C. R. Schaffhausen[1], M. Bruin[2], S. Chu[2], J. Snyder[3], M. Hertz[4], M. Valapour[5], B. Kasiske[6], A. Israni[1], *[1]Hennepin Healthcare Research Institute, Minneapolis, MN, [2]College of Design, University of Minnesota, Minneapolis, MN, [3]Scientific Registry of Transplant Recipients, Minneapolis, MN, [4]Medical School, University of Minnesota, Minneapolis, MN, [5]Pulmonary Medicine, Cleveland Clinic, Cleveland, OH, [6]Nephrology, Hennepin Healthcare, Minneapolis, MN*

Purpose: Criteria for selecting lung transplant candidates and donors vary between programs and evolve as clinical practice advances. This variation impacts patient outcomes and the experiences of patients in need of lung transplant. Existing public reports, such as the Scientific Registry of Transplant Recipients (SRTR) program-specific reports (PSR) are not easily interpreted by patients and do not offer customization to individual patients. We aimed to evaluate lung transplant patients' feedback on prototypes of an online search tool that provides users with patient-specific information on waitlist and transplant outcomes from SRTR.

Methods: We conducted 3 focus groups and 2 interviews with lung transplant recipients and candidates, respectively (n=22). Participants reviewed printouts of the SRTR PSR and prototypes of a patient-specific search tool to evaluate its efficacy for identifying variations between transplant programs that can improve access and reduce wait times (Figures 1). Participants were also asked to reflect on their own decision making and experiences when selecting a transplant program.

Results: Feedback on prototypes of the patient-specific search was positive and included recommendations for improving the tool's efficacy for decision making. Participants revealed a range of experiences related to healthcare decision making and patient education that bring into relief anxieties about accessing the transplant waitlist (Table 1). Knowledge gaps around candidate acceptance practices and apprehensions about having to relocate for transplant care compounded anxieties around decision making.

Conclusions: Patients value a tool that communicates patient-specific information on program-level variations in waitlist and transplant outcomes and variations in donor acceptance practices. The patient-specific search tool will be available at www.transplantcentersearch.org.

Abstract# 1210

Evaluation of Pepsin in Bronchoalveolar Lavage Fluid Post-lung Transplantation: Implications of Detection

M. T. Olson, C. Rogers, K. McAnally, A. Arjuna, *Norton Thoracic Institute, St. Joseph's Hospital and Medical Center, Phoenix, AZ*

Purpose: This preliminary investigation in three lung transplant recipients aimed to measure pepsin, as a marker of gastric microaspiration, in bronchoalveolar lavage fluid (BAL) fluid, and relate its detection to gastroesophageal reflux disease (GERD) status, acute cellular rejection (ACR) episodes, and trends in pulmonary function.

Methods: We analyzed BAL washings and transbronchial biopsies obtained during post-transplant surveillance bronchoscopies for quantitative pepsin levels and acute rejection episodes, respectively. Gastroesophageal function was evaluated pre-transplant and at 3-months post-transplant. Our preliminary investigation included three bilateral lung transplant recipients with pre-transplant GERD (DeMeester scores ≥14.7): 48-year-old female with scleroderma-related interstitial lung disease (patient A), 76-year-old male with combined pulmonary fibrosis and emphysema (patient B), and 73-year-old male with nonspecific interstitial pneumonia (patient C).

Results: Pre-transplant GERD evaluation revealed esophageal peristalsis, delayed esophageal emptying, and DeMeester score of 50.0 in patient A, and mild

esophageal dysmotility in patients B and C, with DeMeester scores of 32.4 and 17.5, respectively. One-month transbronchial biopsy findings were consistent with mild (A2B0) ACR in patient A, and no ACR in patients B and C. Post-transplant GERD evaluation revealed esophageal aperistalsis and DeMeester score of 86.7 in patient A, hypertensive lower esophageal sphincter with normal motility, but DeMeester score of 27.8 in patient B, and grossly normal esophageal function without GERD in patient C. Six-month transbronchial biopsies did not show ACR in any patients. One-year and 15-month transbronchial biopsies were available for patient C and showed two episodes of mild (A2B0) ACR. Elevated pepsin quantities detected in BAL washings and pulmonary function trends are shown in Figure 1.

Conclusions: These early findings demonstrate the utility of measuring pepsin quantity in BAL fluid post-lung transplant. Its quantity on serial detection in lung transplant recipients may have relation to GERD status, acute rejection episodes, and pulmonary function. It also provides confirmatory evidence of reflux-induced microaspiration.

Abstract# 1211

A Retrospective Analysis of the Safety and Efficacy of Apixaban After Lung Transplant

T. Sam[1], K. Reininger[2], R. Patel[1], C. Naik[1], K. Ausloos[1], R. Rosenblatt[1], T. Grazia[1], I. Lam[3], *[1]Transplant, Baylor University Medical Center, Dallas, TX, [2]Transplant, Hennepin County Medical Center, Minneapolis, MN, [3]Transplant, Sharp Memorial Hospital, San Diego, CA*

Purpose: Atrial arrhythmias and venous thromboembolism (VTE) are common after lung transplant. While direct acting oral anticoagulants (DOACs) have become anticoagulants of choice in atrial arrhythmias and VTE, safety and efficacy have not been established in lung transplant, where drug interactions with DOACs are also often present. This study sought to evaluate outcomes with apixaban use after lung transplant.

Methods: We retrospectively reviewed consecutive adult lung transplant recipients between October 15, 2015 and December 31, 2018. Patients were included if they received apixaban for 30 days or more for VTE or atrial arrhythmias, and had 12 months of documented follow-up from the start of apixaban. The primary outcome was a composite of adverse events defined as major bleeding, clinically relevant non-major bleeding (CRNMB), recurrent or breakthrough VTE, and stroke. Bleeding was classified as major or CRNMB using criteria set by the International Society on Thrombosis and Haemostasis.

Results: Twenty-eight patients received apixaban. Fifteen patients received concomitant CYP3A4 or P-gp inhibitors, and 4 of these patients received strong CYP3A4 inhibitors. Six patients (20%) were started on reduced doses for drug interactions or based on clinical judgement. The primary composite endpoint occurred in two patients (7.1%). One CRNMB event occurred in a patient with a gastrointestinal bleed secondary to gastric ulcer, and another patient developed breakthrough lower extremity DVT on apixaban. Drug interactions were not present in the patient who experienced CRNMB. Dose reduction of the loading dose was observed in the recurrent DVT event. No patient experienced a stroke during the follow-up.

Conclusions: Apixaban appears safe and effective in lung transplant patients. Appropriate dosing and adjusting for interactions are critical for optimal outcomes. Larger studies are warranted to assess long-term outcomes as well as safety and efficacy of alternative DOACs.

Abstract# 1212

Pathology of the Explanted Lungs and Surveillance Allograft Biopsy in 202 Lung Transplant Cases: Single Institution Experience

S. Sathirareuangchai[1], S. Moore[1], Q. Cai[1], L. De Las Casas[1], J. Joerns[2], J. Torrealba[1], *[1]Pathology, University of Texas Southwestern Medical Center, Dallas, TX, [2]Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX*

Purpose: This study correlates lung transplantation outcomes with pathologic diagnoses of explants and surveillance transbronchial allograft biopsies.
Methods: A retrospective IRB approved review of archival material from explanted lung recipients from our Department of Pathology database during the period 2013-2016 was performed. Demographic information, explant diagnoses, relevant clinical history, chronology of significant clinical events, and cause of death were retrieved. The results of surveillance allograft biopsies and serum donor specific antigen (DSA) antibodies were also reviewed. Log rank test was used to determine differences in survival among various groups.

Results: 202 patients with end-stage lung disease underwent lung transplant during the 4-year study period. The most common explant diagnoses were emphysema (n=63, 31.2%), usual interstitial pneumonia (UIP; n=62, 30.7%), and cystic fibrosis (CF; n=22, 11%). Eighty-eight (43.6%) recipients died during the study period. The most common causes of death were chronic lung allograft dysfunction (n=25, 28.4%), malignancy (n=18, 20.5%), and infection (n=17, 19.3%). Three deaths were related to Coronavirus Disease 2019 (COVID-19). The overall survival rates at 3-year and 5-year were **74.3%**, and **62.9%**, respectively. Although overall survival rates did not correlate with explant diagnoses, patients with UIP and non-specific interstitial pneumonia (NSIP) tended to have worse outcomes than those with emphysema and CF, with lower survival rates in the first year post-transplant. Allograft rejection was identified in 139 patients (68.8%). Most cases of rejection showed acute cellular rejection (ACR, n=126), while antibody-mediated rejection (AMR) was seen in 29 patients, and a combination of ACR and AMR was found in 15 patients. Patients with early ACR (≤ 90 days post- transplant, n=80) had a lower overall survival rate compared to those with late ACR (> 90 days post-transplant, n=46) with a median survival of 68 *vs.* 88 months, respectively $p<0.05$ (Figure 1). In addition, patients with AMR alone tended to have lower survival than patients with both ACR and AMR (median survival 48 *vs.* 68 months), but not significant ($p=0.07$).
Conclusions: This study demonstrates chronic obstructive pulmonary disease (COPD) as the most common indication for lung transplantation in our cohort. Early ACR was associated with adverse outcome by having lower overall survival rate.

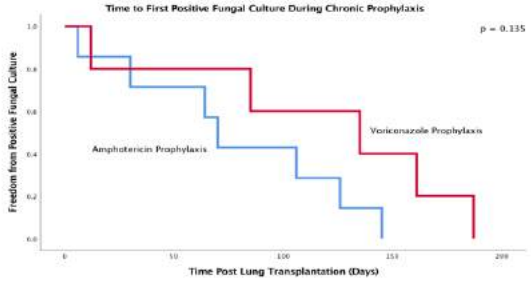
Abstract# 1213

Evaluation of Fungal Prophylaxis Post-Lung Transplantation

I. Shah[1], K. Mohrien[1], C. Rose[2], J. Au[1], *[1]Temple University Hospital, Philadelphia, PA, [2]Temple School of Pharmacy, Philadelphia, PA*

Purpose: Fungal infections are responsible for approximately 15-35% of all infections in lung transplant recipients; 80% of which are due to aspergillus or candida. At our institution, voriconazole and inhaled amphotericin B are used for primary fungal prophylaxis post-lung transplantation for a total duration of six months. The objective of this study was to compare the time to first positive fungal culture in patients receiving voriconazole or inhaled amphotericin B.
Methods: This retrospective, single-center, chart review included adult patients, who received a lung transplant at TUH between January 2012 and June 2019 and continued follow up for at least one-year post-transplantation. The primary endpoint was the time to first positive aspergillus (blood or respiratory) or candida (blood only) culture within six months of lung transplantation. Secondary endpoints included the incidence of positive fungal cultures at one-year and the need for discontinuation of prophylaxis due to adverse events.
Results: Five hundred sixty-eight patients were screened for eligibility, 439 patients were included in the efficacy analysis and 471 patients were included in the safety analysis. Voriconazole was switched to inhaled amphotericin B in 55.9% of patients receiving it for initial prophylaxis and 19.3% of patients receiving it for chronic prophylaxis due to adverse events. The most common reasons for the switch were altered mental status and elevated liver function tests, respectively.

Figure 1: Time to first positive fungal culture at 6 months



Key demographics and secondary endpoints				
Variable	All Patients (n = 439)	Amphotericin (n = 305)	Voriconazole (n = 134)	P Value
Age	64.32 ± 8.93	64.74 ± 9.07	63.35 ± 8.54	0.133
Male	290 (66.1)	205 (67.2)	85 (63.4)	0.441
Double Lung Transplant	163 (37.1)	106 (34.8)	57 (42.5)	0.171
Positive Fungal Culture	29 (6.6)	18 (5.9)	11 (8.2)	0.370
Positive Aspergillus Respiratory Culture	24 (5.5)	13 (4.3)	11 (8.2)	0.094
Positive Candida Blood Culture	5 (1.1)	5 (1.6)	0 (0)	0.329

Conclusions: Voriconazole and inhaled amphotericin B are both efficacious for fungal prophylaxis post-lung transplantation. There was no difference in the incidence of positive aspergillus cultures between prophylactic regimens. However, all five cases of candida-positive blood cultures were observed in patients receiving inhaled amphotericin B. The small number of positive cultures limit the ability to draw definitive conclusions. A significant number of patients receiving voriconazole required a change in prophylaxis due to adverse events.

Abstract# 1214

Tacrolimus Dose Requirements in Lung Transplant Recipients on Systemic Azole Antifungals: The Influence of Race and Transplant Indication

K. S. Walter[1], T. Wert[1], R. Coakley[2], L. J. Lobo[2], R. A. Evans[1], *[1]Department of Pharmacy, University of North Carolina, Chapel Hill, NC, [2]Department of Medicine, University of North Carolina, Chapel Hill, NC*

Purpose: CYP3A5 polymorphisms, drug interactions, and alterations in gastric absorption impact tacrolimus metabolism. This is important for those at higher risk of expressing these factors, such as African American (AA) and cystic fibrosis (CF) patients. We sought to assess the effect of race and transplant indication on tacrolimus dose requirements (TDRs) and transplant outcomes in lung transplant recipients (LTRs) initiated on a fixed tacrolimus dose and antifungal prophylaxis with a systemic azole after transplant.

Methods: All adult LTRs transplanted from 1/2015-10/2019 initiated on an equivalent tacrolimus dose posttransplant were included and stratified by race (AA or non-AA) and transplant indication (CF or non-CF). TDRs, tacrolimus levels, tacrolimus time in therapeutic range (TTR), systemic azole use, biopsy proven acute rejection (BPAR), and patient/graft survival for the first year posttransplant were evaluated.
Results: 68 LTRs were included (10 AA, 16 CF); approximately 90% were on a systemic azole at 1 and 3 months posttransplant. CF LTRs were significantly younger (32 vs 59 years) and had a mean lower body weight (53.4 vs 81.1 kg) at baseline compared to non-CF LTRs. In AAs, TDRs were significantly higher throughout the first year posttransplant, while in CF LTRs, TDRs were only significantly higher throughout the first 3 months posttransplant (Figures 1, 2). There was no difference in time to first therapeutic level or number of dose adjustments to achieve this level between groups. The majority of LTRs did not have a therapeutic tacrolimus level at discharge (55% AA vs 41% non-AA, p=0.1; 63% CF vs 73% non-CF, p=0.4). Tacrolimus TTR was similar between groups (55% AA vs 41% non-AA, p=0.1; 34% CF vs 45% non-CF, p=0.2). No difference in BPAR or patient/graft survival within 12 months was observed.
Conclusions: While both AA and CF LTRs had significantly higher TDRs to maintain similar trough levels, this did not influence transplantation outcomes. Further research is needed to determine the optimal dosing strategy in these patient populations immediately posttransplant.

Abstract# 1215

Bilateral Lung Transplantation for Destroyed Lungs with Asymmetric Thorax

B. Yue, J. Chen, *Wuxi People's Hospital Affiliated to Nanjing Medical University, Wuxi, China*

Purpose: Destroyed lungs can cause mediastinal displacement, asymmetric chest deformity, and high risk and difficulty of surgery. Until now, there are few reports about bilateral lung transplantation for destroyed lungs with asymmetric thorax. In this paper, we report two methods of bilateral lung transplantation for destroyed lungs with asymmetric thorax and introduce our clinical experience.
Methods: A total of six patients with destroyed lungs from 2005-2020 were included in the study. Six candidates received bilateral LT in this period of time at Wuxi Center. Clinical data of the three patients were collected to investigate the safety and feasibility of the surgery.
Results: Three patients used the anterolateral incision in the lateral position without transecting the sternum while three patients used the clam-shell incision in the supine position with transecting the sternum. Only one patient in the lateral position group was assisted by V-A ECMO during the operation; three patients in the lateral position group underwent size-matched lung transplantation. The right upper lobe, right lower lobe, and left upper lobe were removed respectively. In the supine position group, only one patient underwent size-matched lung transplantation, with the right middle lobe removing. For the other two patients, we separated mediastinal adhesions to promote mediastinal reposition. All patients were successfully transferred to ICU for monitoring and treatment.Patients in the lateral position group had more blood loss, operation time, and postoperative hospital stay compared to the supine position group. However, there was no significant statistical difference. One month after the operation, CT illustrated that the donor's lung was well expanded, and the mediastinum was reset.
Conclusions: It is safe and feasible with sufficient preoperative preparation and evaluation for patients with destroyed lungs. The surgical method in the supine position can restore the mediastinum by loosening the mediastinal adhesions, contributing to preserving the lung function of the donor's lung to the greatest extent. The surgical method in the lateral position has a better field of vision and is easier to remove the destroyed lung, especially for patients with old tuberculosis.

Abstract# LB 89

Incidentally Detected Malignancies in Lung Explants: Single Center Case Series

D. Razia, A. Arjuna, L. Schaheen, J. Huang, M. Smith, R. Bremner, R. Walia, *Thoracic Surgery and Lung Transplantation, Norton Thoracic Institute, St. Joseph's Hospital and Medical Center, Phoenix, AZ*

Purpose: Thoracic malignancies are difficult to prospectively diagnose in patients with end-stage lung disease due to complex radiologic features. We present a series of lung transplant (LTx) recipients with incidentally diagnosed malignancies in native lung explants.
Methods: For this retrospective series, we reviewed our LTx registry over 10 years (2011-2020) for malignancy on the lung explant. Histopathology, computed tomography (CT), and positron emission tomography (PET) scans were recorded. Before LTx, a new or expanding pulmonary nodule (PN) was defined as a CT correlative lesion. Endpoints were survival, acute cellular rejection (ACR), and antibody-mediated rejection (AMR).
Results: Of 855 LTx recipients during the study period, 1.3% (n=11) had an explant malignancy. The median age was 68 years, and 55% (n=6) were ex-smokers (median, 25 pack-years). A CT correlative lesion was present in 3 patients; PET demonstrated a metabolically inactive PN in 2 of the patients, and a biopsy in the third suggested coccidiomycosis. The median (range) time between CT and LTx was 58 (16-414) days. All LTx were bilateral. The predominant explant histology was adenocarcinoma (AC; Table 1). The median (range) tumor size was 2.7 (0.4-19)

cm. Nodal involvement was seen in 36% (N1 in 3 patients and N2 in 1). Mycophenolate mofetil was stepped down in all patients, and everolimus was used in 18% (n=2) of patients. Cisplatin and pemetrexed chemotherapy was used in 2 patients, and palliative radiation in 2. ACR was present in 27% (n=3) of patients and AMR was treated in 18% (n=2). Overall, 55% (n=6) of patients were alive, 45% (n=5) of whom were cancer-free (CF). Mean survival was 26±25 months.

Patient	Lung disease	Explant histology	Stage	Alive	Survival (mo)	Outcome/ cause of death
1	COPD	Invasive AC	IIA	No	48	M
2	COPD	AC (acinar)	IB	Yes	86	CF, ACR
3	COPD	Invasive AC (papillary)	IB	Yes	24	CF
4	COPD	Keratinizing SCC	IA1	Yes	5	CF
5	IPF	AC	IA1	No	7	Failure to thrive
6	IPF	AC (papillary)	IIB	No	48	M, ACR
7	IPF	Invasive AC (lepidic), in AC in situ	IIIA	No	5	M
8	IPF	Follicular lymphoma	Low grade	Yes	31	CF
9	IPF	Invasive nonmucinous AC (lepidic)	IIB	Yes	9	CF
10	CPFE	AC (acinar, micro-papillary)	IIIB	Yes	13	M, AMR
11	CPFE	Invasive AC (acinar, lepidic)	IIIA	No	12	M, ACR, AMR

Conclusions: Explanted native lungs can have incidentally detected primary malignancy. Pneumonectomy was curative in squamous cell carcinoma (SCC) and lymphoproliferative disorders. For AC, metastases (M) and allograft rejection from changes in immunosuppression were major causes of a guarded prognosis. Recipients with explant cancers ≥ stage III had poor short-term survival.

Abstract# 1246

Use of Immune Checkpoint Inhibitors in Solid Organ Transplant Recipients: A Scoping Review

A. G. Anderson, M. Eubank, K. Murray, *University of Missouri, Columbia, MO*

Purpose: Immune checkpoint inhibitors (ICI) are an emerging treatment for numerous advanced diseases, but their safety and efficacy in immunosuppressed transplant patients is not known. This study undertakes a scoping review of research on ICI use in solid organ transplant (SOT) recipients to determine: 1) What is the effect of ICI on SOT recipients?; 2) What factors influence the effect of ICI on SOT recipients?

Methods: Data Sources: Searches of PubMed, Scopus and MEDLINE were performed with language restrictions on September 1, 2020. **Study Selection**: Any studies that reported the use of ICI in patients with a history of SOT were included irrespective of study design. **Data Extraction**: Three reviewers independently screened citations and performed data abstractions. A variety of variables were extracted from each publication. **Data Synthesis**: Of the total 549 screened articles, 50 articles met inclusion criteria with a sum of 101 cases of ICI use in patients with a history of SOT.

Results: Graft rejection occurred in 42% (n=42) of the cases. Kidneys were the most commonly rejected organ (n=28) with PD-1 inhibitors being the often-implicated etiology (n=32). Nearly 100% of the cases of graft rejection transpired within 2 months of ICI initiation. Patients on steroid monotherapy had higher rejection rates (72%, n=13) versus those on a steroid plus one or more immunosuppressive agents. In cases where graft preservation was pursued, salvage occurred 33% of the time (n=9). Regardless of graft outcomes, patient outcomes were overall poor due to advanced disease. In cases where patient outcome was reported, 71% (n=39) died directly from disease progression.

Conclusions: ICI offer a promising therapeutic alternative to traditional chemoradiation for patients with advanced malignancies. However, their use in patients with a history of SOT poses a significant risk to the transplanted organ and cancer outcomes are worse in patients with SOT. Future studies are needed to delineate the risk and benefit more clearly.

Abstract# 1247

Pd-1 Inhibitor Treatment in Solid Organ Transplant Patients with Metastatic Cancer

C. Chung[1], H. Ko[1], H. Kim[1], K. Choi[1], A. Han[1], S. Min[1], H. Kang[2], J. Ha[1], *[1]Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic of, [2]Department of Pediatrics, Seoul National University College of Medicine, Seoul, Korea, Republic of*

Purpose: Solid organ transplant patients due to chronic immunosuppression have an increased risk of de novo cancer. Immune checkpoint inhibitors have been recently developed to treat cancer, however, solid organ transplant recipients with cancer have been excluded from clinical trials due to risk of rejection and graft failure. The purpose of our study was to evaluate the outcomes of immune checkpoint inhibitor therapy in solid organ transplant patients with metastatic cancer

Methods: Solid organ transplant patients with metastatic cancer who underwent immune checkpoint inhibitor treatment until 2020 at Seoul National University hospital were retrospectively reviewed. We evaluated the tumor response, rejection, graft failure and overall survival after PD-1 treatment, either nivolumab or pembrolizumab.

Results: Total of six solid organ transplant recipients, 2 kidney and 4 liver transplant, with metastatic cancer who received PD-1 inhibitor treatment were included in the study. The type of primary cancer consisted of 2 hepatocellular carcinomas, 2 skin cancers and 2 lung cancers. 4 patients were diagnosed with cancer more than 10 years after transplantation (124.30-288.63 months) and the other two patients at 7.50 and 17.33 months. There was an addition of mTOR inhibitor after cancer diagnosis for 3 patients, however, there was no change in the immunosuppressive regimen after PD-1 inhibitor treatment for all six patients. The median overall survival was 9.18 (2.73-16.80) months since the start of PD-1 inhibitor treatment. There was no rejection or graft failure. Only 2 out of the 6 patients with stable disease continued more than 4 cycles and eventually all six patients showed progression of disease. There were two deaths related to infections such as atypical pneumonia and sepsis due to urinary tract infection.

Conclusions: Solid organ transplant recipients had no rejections or graft loss after PD-1 inhibitor treatment for metastatic cancer. Further multicenter retrospective studies are needed to evaluate the efficacy and rejection risk of PD-1 treatment in transplant population.

Abstract# 1248

Cancer-Specific Mortality in Solid Organ Transplant Recipients with a Prior Cancer Diagnosis

E. Engels[1], G. Haber[1], A. Hart[2], C. Lynch[3], J. Li[4], K. Pawlish[4], B. Qiao[5], K. Yu[1], R. Pfeiffer[1], *[1]Natl Cancer Inst, Bethesda, MD, [2]Univ of Minnesota, Minneapolis, MN, [3]Univ of Iowa, Iowa City, IA, [4]New Jersey Dept of Health, Trenton, NJ, [5]New York State Dept of Health, Albany, NY*

Purpose: A history of cancer is increasingly common among solid organ transplant candidates, and transplant-associated immunosuppression may increase recurrence risk. We assessed whether transplantation was associated with an elevated mortality among cancer patients.

Methods: Using linked data from the US transplant registry and 13 cancer registries, we compared overall and cancer-specific mortality among cancer patients with vs. without a subsequent transplant. We used Cox regression in cohort and matched control analyses, controlling for demographic factors and cancer stage.

Results: The study included 10,524,326 cancer patients with 17 cancer types; 5425 (0.05%) subsequently underwent transplantation. The median time from cancer diagnosis to transplantation was 4.17 years. Transplantation was associated with elevated overall mortality for most cancers, especially for cervical, testicular, and thyroid cancers (adjusted hazard ratios [aHRs] 3.43-4.88). In contrast, as shown in the table for selected cancer sites, transplantation was not associated with elevated cancer-specific mortality for any cancer site, and we observed inverse associations for patients with breast cancer (aHRs 0.65-0.67), non-Hodgkin lymphoma (0.50-0.51), and myeloma (0.39-0.42).

Conclusions: Among US cancer patients, an increase in overall mortality associated with transplantation is due to adverse effects of end-stage organ disease and transplant-related medical complications. However, there was no elevation in cancer-specific mortality, likely reflecting careful candidate selection. These results support current practices involving wait times and thorough evaluation of potential transplant candidates with previous cancer diagnoses.

Abstract# 1249

Review of Outcomes After Diagnosis of Malignancy in Kidney Transplant Patients: Unos Database

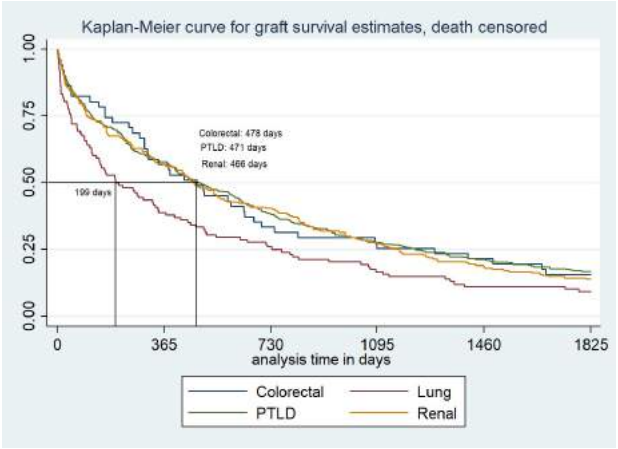
H. Patel[1], N. Agrawal[1], R. Gupta[1], P. Geetha[2], A. Abdul Razzack[3], F. Cardarelli[1], *[1]Transplant Nephrology, Beth Israel Deaconess Medical Center, Boston, MA, [2]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA, [3]Medicine, Dr. NTR University of Health Sciences, Vijaywada, India*

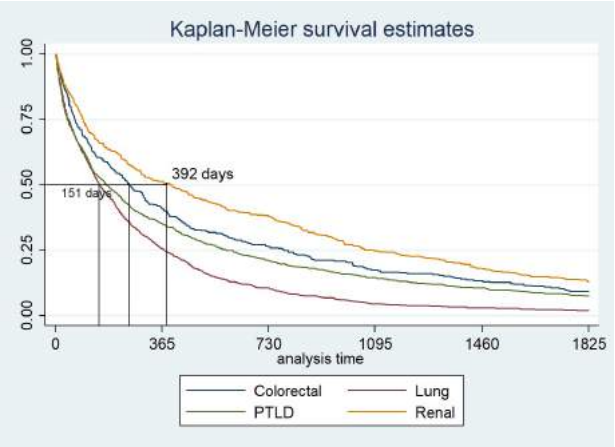
Purpose: Malignancy is the third major cause of death among transplant recipients. Among the transplant recipients, Patient and kidney transplant outcomes after the diagnosis of malignancy are not well described. With this study we review incidences and outcomes of Colorectal, Lung, PTLD, and Renal malignancy after transplant.

Methods: It is a retrospective study of patients of who received transplant from January 2000 to December 2018 using UNOS/OPTN database. Incidence of each malignancy have been measured at 5 years and 10 years of transplant. Kaplan Meier curve was used for time to event analysis (graft and Patient outcomes). Additionally, we sought to identify the causes of graft failure among these recipients.

Results: Total 12,764 (5.5%) of patients have suffered malignancy (non-squamous/basal cell skin carcinoma) after transplant. During first 5 years of transplant, Incidence of Colorectal, Lung, PTLD, and Renal malignancies were 2.99, 9.21, 15.61 and 8.55 per 10,000 person years, respectively. Rate of graft failure was 10.3%, 7.6%, 19.9%, and 18.8% respectively among these patients.

Conclusions: In this study, kidney transplant recipients who are diagnosed with lung malignancy have the lowest patient and graft survival, compared to PTLD, colorectal and renal malignancy. PTLD has the highest incidence rate in the first 5 years of transplant; however, between 5-10 years from transplant lung malignancy has the highest incidence followed by PTLD, renal and colorectal malignancies. The most common cause of graft failure in this patient population is chronic rejection, followed by malignancy complications and acute rejection.





Graft and Patient survival rate and time after malignancy				
Malignancy	Death censored graft failure	Diagnosis to graft survival time (days)	Total number of deaths	Time from Diagnosis to death (days)
Colorectal	**51 [10.3%]**	**478 [163 – 1292]**	**304/494 [61.5%]**	**254 [68 – 781]**
Lung	**108 [7.6%]**	**199 [45 – 733]**	**1190/1416 [84%]**	**151 [45 – 373]**
PTLD#	**386 [19.9%]**	**471 [118 – 1226]**	**950/1936 [49.1%]**	**175 [41 – 585]**
Renal	**210 [18.8%]**	**466 [100 - 1169]**	**396/1115 [35.5%]**	**392 [95 – 1089]**

Deceased Donor Management and Intervention Research

Abstract# 1250

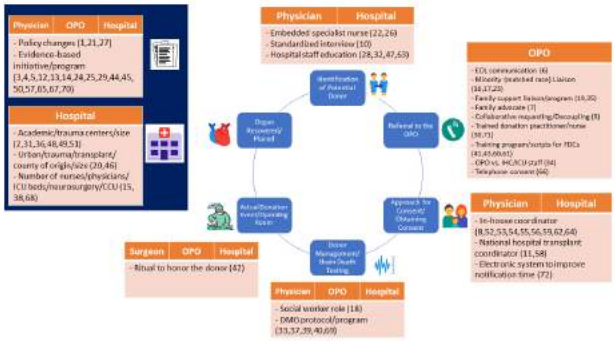
Hospital-Level Metrics and Interventions to Increase Deceased Organ Donation: A Systematic Review

M. Castillo-Angeles[1], G. Li[2], P. Bain[3], A. Salim[1], J. T. Adler[1], *[1]Surgery, Brigham and Women's Hospital, Boston, MA, [2]Brandeis University, Waltham, MA, [3]Harvard Medical School, Boston, MA*

Purpose: The shortage of transplantable organs available for the ever-growing transplant waiting list is well-described. Efforts to ameliorate this have predominantly focused on improving processes and interventions at multiple levels in the organ donation process, but no comprehensive review of hospital-level factors exists. We undertook a systematic review of the literature to better understand what is known and what is not known about hospital-level factors associated with successful organ donation.

Methods: We searched four electronic databases (PubMed, Embase, CINAHL, Web of Science, Health Business Elite, and Google scholar) and conference abstracts for articles on any hospital-level factors associated with the final outcome of organ donation (PROSPERO CRD42020187080). Editorials, letters to the editor, and reviews without original data were excluded. Our main outcomes were conversion rate, donation rate, number of organs recovered, number of donors, and consent rate.

Results: Our search yielded 2,203 studies, and after a thorough assessment, 72 articles were included in this systematic review. Studies were thematically categorized into 1) Hospital-level interventions associated with metrics of organ donation; these included patient- and family-centric measures (i.e. standardized interviews, collaborative requesting and decoupling, and dedicated in-house coordinators), and donor management goals that significantly increased conversion rates by up to 64%; 2) Hospital-level multi-stage programs/policies; which increased consent rates between 30 and 50%; and 3) Hospital characteristics and qualities; being an academic center, trauma center and larger hospital correlated with higher consent and conversion rates. Figure shows the contribution of these studies at each step in the donation process.



Conclusions: There is a lack of well-designed studies on hospital-level factors and interventions associated with organ donation. The use of thoughtful, patient- and family-centric approaches to consent generally is associated with more organ donors. Future work can build on what is known about the hospital role in organ donation to first collaborate with OPOs, and then to use this knowledge and collaboration to improve OPO performance.

Abstract# 1251

Public Perceptions of Presumed Consent for Organ Donation in Canada: A Qualitative Descriptive Study of Public Comments from News Articles

D. E. Fox[1], M. Donald[2], C. Chong[1], R. R. Quinn[3], P. E. Ronksley[1], M. J. Elliott[3], N. N. Lam[3], *[1]The Department of Community Health Sciences, The University of Calgary, Calgary, AB, Canada, [2]Cumming School of Medicine, The University of Calgary, Calgary, AB, Canada, [3]The Cumming School of Medicine and Department of Community Health Sciences, The University of Calgary, Calgary, AB, Canada*

Purpose: In 2019, two Canadian provinces (Alberta and Nova Scotia) became the first jurisdictions in North America to pass presumed consent legislation to increase deceased donor organ transplantation. Under this law, adults will be presumed to consent to organ donation unless they register an opt-out decision. Public trust and support for the policy is critical to its success and fears and misconceptions need to be identified and addressed.

Methods: We performed a qualitative descriptive study to explore public perceptions and perceived implications of presumed consent for organ donation in Canada. We extracted public comments from online articles published by 4 major Canadian news outlets about the presumed consent policy from January 2019 to July 2020. Articles were excluded if they: 1) were not in the English language, 2) had no comments, or 3) did not focus primarily on presumed consent. Comments linked to the articles were imported into NVivo. Conventional content analysis (i.e., coding and grouping similar concepts and developing themes) was completed independently by two authors.

Results: We identified 180 news articles; 36 were eligible for study inclusion and contained a total of 4,357 comments for data analysis. Three primary themes emerged: polarized positions on the bill, perceived implications of the bill, and questions or concerns to address. The majority of commenters appeared to be either for or against the bill, with few people reporting neutral views. This resulted in tensions between the two sides. The perceived positive implications of the bill included: a) it aligned with the views of the majority of Canadians, b) it had lifesaving and financial benefits, and c) it was a timely and sensible solution. The perceived negative implications included the bill being: a) a violation of rights, b) having the potential for abuse, and c) it being a slippery slope (e.g. it could lead to a monetized organ trade). Improving government transparency and communication, clarifying questions and concerns, and providing evidence for the bill were identified as key concerns that need to be addressed prior to implementation.

Conclusions: Public perceptions of the presumed consent bill for organ donation in Canada are influenced by various factors. If the presumed consent laws are meant to increase organ donation and transplantation, public education and support will be important to ensure successful implementation.

Abstract# 1252

Donor CPR and Solid Organ Transplantation

E. Larsen[1], K. Cardoza[2], K. Robichaux[3], A. Kumar[1], V. Bowers[4], J. Buggs[4], *[1]Morsani College of Medicine, University of South Florida, Tampa, FL, [2]Honors College, University of Tampa, Tampa, FL, [3]Honors College, University of South Florida, Tampa, FL, [4]Transplant Surgery, Tampa General Hospital, Tampa, FL*

Purpose: In 2010, the American Heart Association and Emergency Cardiac Care (AHA ECC) set a 10-year impact goal of doubling cardiac arrest survival by 2020. The intention of cardiopulmonary resuscitation is always to save the life of a patient; however, some studies suggest donor CPR may improve outcomes in recipient graft survival. The purpose of this study was to determine if the number of organ donors receiving CPR would correlate with the efforts of the AHS ECC impact goal of doubling cardiac arrest survival from 2010 to 2020.

Methods: We conducted a retrospective study of the CPR status of deceased organ donors from January 2010 to December 2019. Deidentified publicly available data from the United Network for Organ Sharing (UNOS) was utilized for the analysis. Patients were grouped by donation year. A sub-analysis was performed on the recipients of kidneys from donors who received CPR during our study period.

Results: There were N=90,689 donors in our 10-year study. Figure 1 demonstrates the increase in donors who received CPR from 35% (2,689/7,765) in 2010 to 55% (6,361/11,560) in 2019, (p=0.014) We then analyzed the 47,029 organ donors who received CPR with kidneys utilized for transplantation. Figure 2 demonstrates a 2.4-fold increase in the number of females who received a kidney transplant from a donor who received CPR in 2010 (1,609) vs. 2019 (3798). There was a 2.5-fold increase for male patients who received a kidney transplant from a donor who received CPR in 2010 (2354) vs. 2019 (5,821), p<0.001. In Figure 3 we analyzed the organ donors who received CPR by race/ethnicity and found that the rate of CPR more than doubled in all ethnic groups over the course of the study (p<0.001).

Conclusions: In conclusion, the number of organs from donors who received CPR more than doubled over the past decade correlating with the goal of the AHA ECC efforts to double the survival of cardiac arrest. Lives were saved because more people received successful CPR and lives were saved because more organs were transplanted from donors who received CPR for males and females and across all ethnic groups.

Abstract# 1253

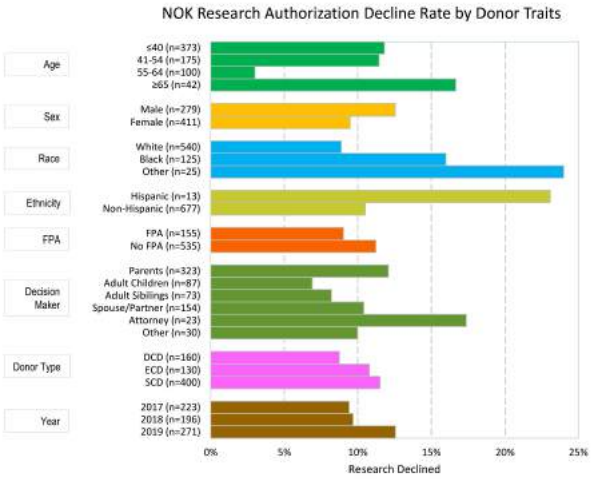
Variation in Next of Kin Authorization for Research in Deceased Donor Organ Transplantation: Experience at One Organ Procurement Organization

K. L. Lentine[1], C. Jones[1], W. Cheungpasitporn[2], R. Rothweiler[3], H. Xiao[1], M. Ortigosa-Goggins[4], G. Marklin[3], R. B. Mannon[5], *[1]Saint Louis University, St. Louis, MO, [2]Mayo Clinic, Rochester, MN, [3]Mid-America Transplant, St. Louis, MO, [4]University of Miami, Miami, FL, [5]University of Nebraska, Omaha, NE*

Purpose: Research related to deceased donor interventions seeks to address diverse questions to improve the use and outcomes of organ gifts for transplantation. Consent for deceased donor research is obtained from the next of kin (NOK) authorizing donation or through first-person authorization (FPA), but to date, there is limited information on patterns of research authorization or how decline rates may impact access to new information for certain groups.

Methods: We performed a retrospective chart review of all deceased organ donors from 1/2017-12/2019 at a large Midwestern organ procurement organization. We determined FPA authorization status, NOK relationship, and final research authorization using the Critical Organ documents and FPA registration records. Multivariable logistic regression analysis was used to assess the association between donor factors and research authorization (adjusted odds ratio, $_{95\%\ LCL}$ aOR $_{95\%\ UCL}$).

Results: Medical records for 688 deceased donors in the study period were reviewed. Of these, 659 (95.5%) had an organ recovered for transplant. Overall, research authorization was provided in 89.2% of donations and declined in 10.8%. Compared to white donors, research decline was higher for Black (16.0% vs 8.9%; aOR, $_{1.05}1.90_{3.43,}$ p=0.05) and other non-white donors (24.0% vs 8.9%; aOR, $_{1.21}3.31_{9.06,}$ p=0.05). Unadjusted research decline was higher for Hispanic donors (23.1% vs 10.5%), but decline was not significantly different with adjustment. Compared to donors age <40, research decline was lower for donors aged 55-64 (3.0% vs 11.8%; aOR, $_{0.07}0.24_{0.84,}$ p=0.05), but higher for donors age 65 and older (16.7% vs 11.8%; aOR, $_{0.95}3.61_{13.79,}$ p=0.05). Ultimate research decline trended lower when donor had provided FPA (9.0% vs 11.2%; aOR, $_{0.24}0.51_{1.08,}$ p=0.05). There was no significant association of research authorization with NOK relationship to donor, donor sex, donor type, or year of donation.



Conclusions: Deceased donor research authorization decline is higher for Black, other non-white donors, and donors older than age 65. These findings may inform educational interventions for both staff and families to improve research authorization rates and increase opportunities to provide science for vulnerable groups.

Abstract# 1254

Intensivist-Performed Transesophageal Echocardiography as a Screen for Organ Donation: A Four-Year, Single-Center Experience

K. M. Madden[1], T. C. Wray[2], K. Rainbird[1], I. Tawil[2], T. Dettmer[2], K. Azevedo[2], R. Venkataramani[3], J. Marinaro[2], *[1]New Mexico Donor Services, Albuquerque, NM, [2]Emergency Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, [3]Anesthesiology, University of New Mexico Health Sciences Center, Albuquerque, NM*

Purpose: Echocardiography is required for deceased heart donation, and transthoracic echocardiography is the traditional practice. At our institution, intensivists perform transesophageal echocardiography (TEE) and since 2016, intensivist TEE has been the primary evaluation method in brain dead (BD) heart donation. We aimed to determine our institution's potential donor heart transplant outcomes after intensivist-performed TEE.

Methods: A retrospective review of eligible BD donors with heart donation potential who underwent TEE was performed to evaluate the TEE interpretation, if the heart was allocated, and if the heart was ultimately transplanted. We also evaluated likelihood of transplant if a repeat TEE was performed.

Results: From 01/01/2016 to 11/09/2020, 74 TEEs were performed on 62 eligible BD donors with heart donation potential. 48 (77%) hearts were allocated, of which 41 had TEEs read as normal. 29 (60%) were ultimately transplanted. Of the 19 hearts allocated but not transplanted, 11 (58%) were read by the intensivist as normal. Table 1 lists reasons eligible donor hearts with normal TEEs were not transplanted. Of the 12 donors requiring a second TEE due to reduced systolic function, the heart was not allocated for 1 (8%). Of the remaining 11, 7 were ultimately transplanted (64%).

Conclusions: Intensivist-performed TEE at our institution resulted in the majority of donor hearts evaluated ultimately being transplanted over the four years studied. Future studies will compare intensivist-evaluated donor heart transplant outcomes with those of the prior transthoracic echocardiography driven era, as well as further examine the optimal time for the first TEE, or the repeat TEE, based on the data we have gathered.

Table 1: Donor Hearts with Normal TEE Not Transplanted (n=11)

Reason	Number of Donor Hearts (%)
List ran, no potential recipient identified	4 (36%)
Significant coronary artery disease on cardiac catheterization	3 (27%)
New vasopressor requirement prior to procurement	2 (18%)
Donor/recipient size mismatch noted in OR	1 (9%)
Development of new right ventricular dysfunction prior to OR	1 (9%)

All Organs

Non-Organ Specific: Organ Preservation/Ischemia Reperfusion Injury

Abstract# 1255

Ex Situ Heart Perfusion and Standard of Care Cold Storage Differentially Affect the Ischemic Secretome of Donor Hearts in Perfusates but Not the Reperfusion Response in Recipient Plasma

E. Chichelnitskiy[1], B. Wiegmann[2], N. Ledwoch[1], F. Ius[2], F. Wandrer[1], J. Kühne[1], K. Beushausen[1], J. Keil[1], S. V. Rojas[2], W. Sommer[2], C. Kühn[2], I. Tudorache[2], M. Avsar[2], A. Haverich[2], G. Warnecke[2], C. S. Falk[1], *[1]MHH, Institute of Transplant Immunology, Hannover, Germany, [2]MHH, Department for Cardiothoracic, Transplantation and Vascular Surgery, Hannover, Germany*

Purpose: Various allograft preservation procedures influence the donor organ status that may be reflected by the cytokine/chemokine microenvironment in heart transplant (HTx) recipients. In addition, the microenvironment in perfusion solutions may be informative in terms of organ function. Therefore, we aimed to compare the secretomes in recipient plasma and perfusates of two cohorts of HTx patients whose hearts were either preserved using *ex situ* heart perfusion (ESHP) or standard of care (SOC) cold static preservation in order to identify potential biomarker candidates for heart preservation.

Methods: Using multiplex techniques, we measured 50 cytokines/chemokines, growth and adhesion factors in recipient plasma before (pre), after (T0), 24 h and 3 weeks after HTx. Donor hearts were preserved either by ESHP (n=30) or SOC (n=22) procedures.
Results: Using unsupervised cluster analyses, the top 10 plasma cytokines and chemokines were identified, clearly separating T0 from other time points after HTx, reflecting a reperfusion injury-specific pattern. Surprisingly, ESHP or SOC heart preservation did not have a significant impact on these inflammatory plasma profiles at T0, T24 or 3 wks. The two strongest discriminators separating T0 from other time points i.e. IFN-γ, SCGF-β (all $p \leq 0.05$) were detected in both ESHP and SOC recipients at comparable concentrations. In contrast, the preservation method clearly affected the cytokine/chemokine profile in perfusates highlighted by higher concentrations of IL-6, IFN-γ, CXCL10, TNF-α, IL-10, IL-1RA, CXCL12, PDGF, G-CSF (all $p \leq 0.05$) in ESHP compared to SOC samples.
Conclusions: Although ESHP or SOC preservation did not affect the reperfusion response in plasma at T0 after HTx, normothermic oxygenated preservation of donor hearts was accompanied by secretion of pro- and anti-inflammatory cytokines, chemokines that may affect long-term functionality and longevity of the graft. With a better understanding of molecular changes during ESHP, we expect to identify biomarker candidates for improved organ function pre HTx.

Abstract# 1256

Combined Liver and Lung Transplantation with Extended Normothermic Liver Preservation Using Transmedics Organ Care System (OCS)™ Liver: A Single Center Experience

J. Konel[1], M. Shamaa[2], O. Shamaa[2], A. Elsabbagh[2], T. Kitajima[2], T. Ivanics[2], K. Delvecchio[2], A. Mohamed[2], S. Yeddula[2], K. Collins[2], A. Yoshida[2], M. Abouljoud[2], S. Nagai[2], M. Rizzari[2], *[1]Wayne State University School of Medicine, Detroit, MI, [2]Henry Ford Transplant Institute, Detroit, MI*

Purpose: Combined liver-lung transplantation (CLLT) is indicated in patients who cannot survive single-organ transplantation alone. Ex-situ normothermic machine perfusion (NMP) has been used to increase the pool of suboptimal donors and has been previously used for extended normothermic lung preservation in CLLT. We aim to describe our single-center experience using the 'Transmedics Organ Care System (OCS) ™ liver' for extended normothermic liver preservation in CLLT.
Methods: Medical records were queried for patients at our center that underwent CLLT from 2015-2020.
Results: [Values shown are represented as mean (standard deviation, range)]: Four CLLTs were performed from 2015 to 2020 including 3 male and 1 female recipients, age 50 (±13.7, 31-61) years (Table 1). Indications for lung transplantation include: (1) cystic fibrosis (CF), (1) severe bronchiectasis, and (2) interstitial pulmonary fibrosis. Indications for liver transplantation include: (1) biliary cirrhosis secondary to CF, (1) cirrhosis secondary to autoimmune hepatitis, (1) alcoholic cirrhosis, and (1) cryptogenic cirrhosis. The lung was transplanted first for all patients. Recipient characteristics at transplant: Mean forced expiratory volume in 1 second (FEV1) was 51% (±22, 29-78) and Model for End-Stage Liver Disease was 12 (±3.7, 8-16). The livers were donated after brain death with donor age of 34 (±9.4, 25-46) years and cold ischemia time 566 (±38, 545-623) minutes. Ex-vivo pump time for the livers was 411 (±38, 364-456) minutes (Table 2). Mean hospital stay was 34 days (±18, 14-161). Over a median follow-up of 201 days, patient and graft survival remain at 100%, though 50% of liver grafts had biopsy-proven acute cellular rejection.
Conclusions: CLLT is a viable treatment option for patients with severe two-organ failure. Normothermic extended liver preservation is a safe method to prolong perfusion time and preserve the liver during combined liver and lung transplantation.

Abstract# 1257

Dual Lactate Clearance in the Liver Viability Assessment During Normothermic Machine Perfusion

M. Xu[1], F. Zhou[1], O. Ahmed[1], J. Shin[1], Y. Zhu[1], G. Upadhya[1], K. Byrnes[2], B. Wong[1], J. Kim[1], Y. Lin[1], W. Chapman[1], *[1]Department of Surgery, Washington University, St. Louis, MO, [2]Department of Pathology and Immunology, Washington University, St. Louis, MO*

Purpose: Liver normothermic machine perfusion (NMP) has been increasingly performed as a tool of organ preservation and to evaluate donor function. The perfusate lactate clearance (LC) is considered as one of the useful indicators of liver viability assessment during NMP. However, the applicable scope and potential mechanisms of LC remain poorly defined.
Methods: We studied the extracellular signal-regulated kinases (pERK1/2) pathway, lactate dehydrogenase A (LDHA), ischemic time, perfusate and bile chemistry, steatosis, hepatic glycogen, inflammatory cell infiltration, necrosis, and apoptosis of the OrganOx Metra device-perfused discarded human livers with successful lactate clearance (sLC, n=5) compared with non-sLC (nLC, n=5) in the perfusate (<2.2mmol/L at 2hr NMP).
Results: We found that the expression of LDHA was significantly higher in the livers with sLC than in the livers without at 2hr NMP ($p=0.031$). In contrast, the pERK1/2 level was substantially higher in the nLC livers than in the sLC livers at 2hr and 6hr NMP (Fig.A, $p=0.035$ and 0.006, respectively). Immunostaining showed that up-regulation of pERK1/2 was in both the hepatocytes and cholangiocytes in the nLC livers (Fig.B). We also found that sLC was associated with a marginally higher glycogen restoration than nLC at 2hr NMP ($p=0.065$). Furthermore, bile

lactate levels in sLC livers were cleared into the normal range at 6hr NMP, but the bile lactate levels were inconsistent in the livers with nLC. H&E staining suggested that the necrosis scores were higher in the nLC than in the sLC livers at 0hr and 6hr NMP (p=0.047 and 0.053, respectively).

Conclusions: The dual lactate clearance in the perfusate and bile can be helpful in evaluating the hypoxic injury of hepatocytes and cholangiocytes following the NMP of discarded human livers.

Abstract# 1258

Intravenous Immunoglobulin Protects Liver Allograft from Ischemia Reperfusion Injury in Human Liver Transplantation

S. Yokota, J. C. Alonso-Escalante, R. P. Tindall, K. R. Tabar, L. Machado, T. Uemura, N. L. Thai, *Department of Surgery, Allegheny General Hospital, Pittsburgh, PA*

Purpose: Ischemia/reperfusion (I/R) injury following prolonged cold storage has a significant impact on early and late human liver transplantation (LTx) outcomes. Prevention of I/R injury would improve the outcome of LTx and potentially expand the limited donor pool by allowing the wider use of marginal organs. Intravenous immunoglobulin (IVIG) has immunomodulatory effects and has been shown to decrease rate of acute rejection in LTx recipients. However, the role of IVIG in prevention of I/R injury is unclear. The aim of this study is to examine if intraoperative IVIG administration would be protective against I/R injury after adult LTx.

Methods: We conducted a retrospective study of deceased donor LTx recipients between 2017-2018 at our center. We compared recipients who received a dose of IVIG intraoperatively (IVIG group, median dose 500mg/kg, n=35) with recipients who did not (control group, n=34). We used the United Network of Organ Sharing data to obtain donor characteristic (age, gender, donation after circulatory death, serum ALT before donor surgery) and conducted chart review of recipients' characteristic data (age, gender, Model for End-Stage Liver Disease Score, indication for LTx), intraoperative variables, postoperative data (serum transaminases, acute rejections, graft survival, patient survival) to compare clinical outcomes between the two groups.

Results: Donor and recipient characteristics were similar between control and IVIG group. Operative time (402 minutes vs 386 minutes), estimated blood loss (2000ml vs 2525ml), units of transfusion (8 units vs 9 units), cold ischemia time (302 minutes vs 286 minutes), and warm ischemia time (31 minutes vs 31 minutes) were not statistically different (all expressed as median, p>0.05). There were no significant differences in intraoperative hemodynamic parameters (mean arterial, pulmonary artery, and central venous pressures) between the two group (p>0.05). Control group had significantly higher level of ALT at 3 hour (390±43 vs 257±28 U/L, p=0.007), 10 hours (359±50 vs 247±36 U/L, p=0.02), and AST at 3 hour (729±96 vs 451±39 U/L, p=0.005) after reperfusion compared to IVIG group; IVIG group had >30% reduction in I/R injury. There was no significant difference in the rate of acute rejection (p=0.47) and recipients` survival (p=0.25, Log rank).

Conclusions: These novel data indicate that intraoperative IVIG administration may be protective against I/R injury after LTx. The result of this study would serve as a foundation for future prospective studies to determine the effect of IVIG in prevention of I/R injury after LTx.

Abstract# 1259

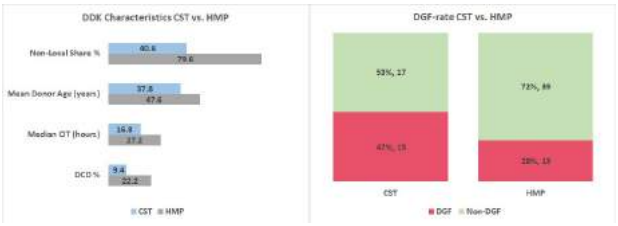
Mitigating the Adverse Impact of Broader Kidney Sharing with Hospital-based Machine Perfusion

Y. Yushkov, B. R. Schleich, T. Carrea, V. Wadhera, M. J. Goldstein, *Hackensack University Medical Center, Hackensack, NJ*

Purpose: The new UNOS kidney allocation changes effective December 2020 will be removing the geographic limits of donation service areas (DSA) and UNOS regions favoring a zone of 250 nautical miles (NM) from the donor hospital. Transplant centers with low waiting times will have access to fewer deceased donor kidneys (DDK) compared to transplant centers in neighboring DSAs with longer waiting times. This change will dramatically reduce locally allocated organs and broaden the sharing distance of lifesaving DDKs for our patients. In order to mitigate the risk of prolonged cold ischemic time (CIT) and to increase utilization of nationally shared kidneys, our center created a hospital-based machine preservation center utilizing hypothermic machine perfusion (HMP) in January of 2020. Implementation of HMP allowed improved evaluation of organs with higher KDPI and increased acceptance of kidneys with longer CIT. It is likely that organ procurement organizations might be less inclined to provide HMP with broader sharing of kidneys, making hospital access to HMP more vital. To our knowledge, only five centers in the US utilize hospital-based HMP.

Methods: A retrospective study compared characteristics and immediate outcomes of two groups of DDKs transplanted between January through October 2020: DDKs preserved with cold storage technique (CST) (N=32), and DDKs preserved using HMP (N=66). After organ evaluation on HMP, due to the higher machine-measured renal resistance and biopsy results, 12 (18.18%) kidneys were discarded and excluded from the study leaving this cohort with 54 kidneys.

Results: Despite having a higher non-local share, a higher mean donor age, a higher median cold ischemic time (CIT), and a higher DCD rate), patients that received HMP kidneys have a significantly lower delayed graft function (DGF) and shorter median length of stay (LOS) compared to patients that received DDKs preserved with CST (p<0.01). No kidney in either cohort had primary non-function.



Conclusions: HMP allowed us to get better access to non-local DDKs as it expanded our ability to evaluate nationally allocated kidneys that were locally declined, improved organ flush characteristics, alleviated risk of prolonged CIT while optimizing kidney function, and improved organ utilization. Other benefits included reduced hospital costs due to reduced LOS and DGF as well as transplanting patients faster and thus decreasing waitlist mortality and disease progression.

Abstract# 1260

Removal of Race Factor in Egfr Decreases Disparities in Preemptive Listing for Kidney Transplantation

Y. Al-Salmay, N. Jandovitz, M. Abate, A. Baez, E. Molmenti, A. Fahmy, N. Breslin, L. Teperman, V. Nair, *Organ Transplantation, Northwell Health, Manhasset, NY*

Purpose: GFR < 20 is required for kidney transplant listing. The Chronic Kidney Disease-Epidemiology Collaboration (CKD-EPI) and the Modification of Diet in Renal Disease (MDRD) equations for estimating GFR incorporate serum creatinine, age, sex and a correction factor for Black race. The aim of this study was to investigate whether eGFR equations contribute to disparities in preemptive listing of black patients.

Methods: We identified all patients added to our kidney transplant waiting list since 2008. GFR at the time of listing was obtained for patients listed preemptively. MDRD equation was used to calculate eGFR until February 2015 then CKD-EPI.

GFR for non-Black patients was modified using the Black race correction factor (1.212 for MDRD, 1.159 for CKD-EPI). The number of patients listed before and after modification was compared in every race/ethnic group.

Results: Among 410 patients on the waiting list, 166 (41%) patients were pre-emptively listed. Black patients made up 36% of the waitlist of whom 29% were preemptively listed. White patients made up 24% of the waitlist of whom 62% were preemptively listed (Table 1).After eGFR modification, a total of 35 patients had an eGFR >20 ml/min and would not qualify for preemptive listing. All non-Black races saw a decrease in preemptive listing.After adjusting for age and gender, White patients had a 4-fold increase in odds of preemptive listing, compared to Black ($p<0.001$). There was a trend towards increased odds of preemptive listing for Asians compared to Black (OR 1.65, p value 0.068). After modification of GFR the OR between White race and preemptive listing decreased to 2.9 ($p<0.001$), and the trend towards higher preemptive listing in Asians disappeared.

Conclusions: Our observations suggest the magnitude of racial disparity in pre-emptive listing would be reduced if race-based calculation of eGFR was removed.

Table 1: Racial distribution of patients on the preemptive kidney transplant waitlist

	Total Waitlist n=410	Listed Pre-emptive n=166			Listed Pre-emptive after eGFR modification n=131		
Race	n (%)	n (%)	Odds Ratio	p-value	n (%)	Odds Ratio	p-value
Black	147 (36)	42 (29)	ref		42 (29)	ref	
White	100 (24)	62 (62)	4.08	<0.001	44 (54)	2.89	<0.001
Asian	98 (24)	39 (39)	1.65	0.07	29 (33)	1.22	0.49
Hispanic	65 (16)	23 (35)	1.37	0.32	16 (27)	2.89	0.93

Abstract# 1261

Impact of Bacterial Infection on HLA Allosensitization Among Kidney Recipients on the Waitlist

D. P. Cina[1], K. R. Sherwood[2], S. Dobrer[2], J. Wong[3], F. Fenninger[2], M. Kadatz[4], P. Keown[4], J. Lan[4], *[1]Department of Urologic Sciences, University of British Columbia, Vancouver, BC, Canada, [2]University of British Columbia, Vancouver, BC, Canada, [3]Department of Laboratory Medicine, Vancouver General Hospital, Vancouver, BC, Canada, [4]Department of Nephrology, University of British Columbia, Vancouver, BC, Canada*

Purpose: The clinical relevance of HLA allosensitization associated with bacterial infection remains poorly defined. The primary objective of this study is to determine the incidence, characteristics, and clinical relevance of post-infectious de novo HLA antibodies (dnHLA) in a cohort of kidney candidates.

Methods: This retrospective study includes adult kidney patients on the waitlist who (1) had a documented bacterial infection; (2) received a HLA antibody assessment via single-antigen bead (SAB) testing pre- and post-infection; (3) had no other sensitizing events between pre- and post-infectious SAB tests. Epitope analysis was performed using HLA Matchmaker v02. Pathogenic epitopes were identified using IEDB.org.

Results: Overall, n=9/30 (30%) developed dnHLA Ab with an average rise in cPRA of 53.2±39.8% (Fig 1). The most common route of infection was PD peritonitis (5/9), with Enterococcus being the most commonly cultured organism. The majority of antibodies were class I, but class II antibodies had a higher median MFI compared with class I (p=?) (Fig 2). In contrast, among patients with pre-existing antibodies only class I antibodies showed an increase in MFI post-infection but not class II. There were no clear cross-reactivity patterns to the dnHLA Ab that formed post-infection. Due to limited data in IEDB, epitopes could not be matched to any of the infectious pathogens.

Conclusions: In this small but well-characterized cohort of waitlisted kidney transplant patients, a significant proportion of patients developed dnHLA Ab after bacterial infection with a concomitant rise in cPRA that could diminish access to transplant. The lack of cross-reactive patterns to these dnHLA Ab indicate they are less likely to be antigen-specific. The MFI strength of these antibodies permit surrogate crossmatches/absorption studies to further evaluate their clinical relevance.

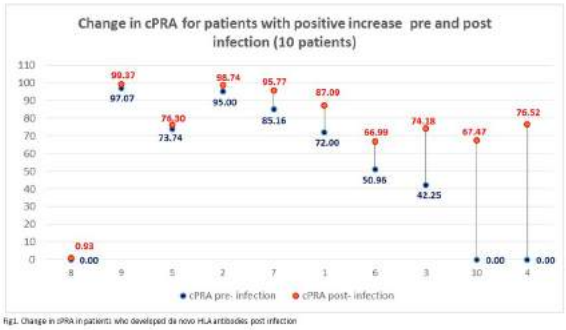

Fig1. Change in cPRA in patients who developed de novo HLA antibodies post infection

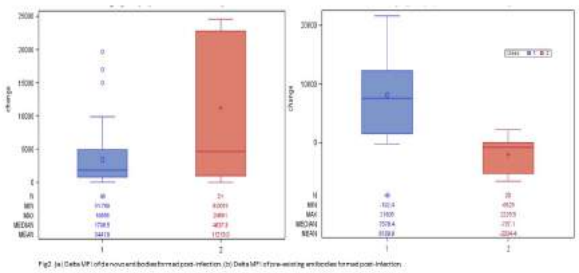

Fig2. (a) Delta MFI of de novo antibodies formed post-infection. (b) Delta MFI of pre-existing antibodies formed post-infection.

Abstract# 1262

Solid Organ Transplant Telehealth Utilization Significantly Increased During the Covid-19 Pandemic: Experience at a Single, Large Volume Center

R. Forbes, K. Kumm, H. O'Dell, K. Smith, L. Smith, A. Dreher, H. Schaefer, B. Concepcion, *Vanderbilt University Medical Center, Nashville, TN*

Purpose: During the COVID-19 pandemic, telehealth utilization has allowed for the delivery of healthcare while protecting patients, caregivers, healthcare workers, and the community from exposure. We examined the effect of the COVID-19 pandemic on utilization of telehealth in the care of all solid organ transplant patients in all phases of transplant care at our center.

Methods: All patients seen at Vanderbilt University Medical Center for solid organ transplant during any phase of care (referral, evaluation, waitlist, or post-transplantation) from July 1, 2019 through October 31, 2020 were included in this retrospective analysis. Patients seen from July 1, 2019 through February 29, 2020 were identified as a Pre-COVID-19 era cohort. Patients seen from March 1, 2020 through October 31, 2020 were the COVID-19 era cohort. Pretransplant phases of care included referral, evaluation and waitlist; those transplanted were considered posttransplant. Telehealth visits included telemedicine, defined as those conducted by face-to-face (F2F) videoconferencing, and telephone.

Results: Total visit number for all solid organs (kidney, liver, heart, lung, and pancreas) were similar between eras (12585 vs. 13677) [Figure]. There was a significant increase in the use of telehealth in the COVID-19 era for all organ types with the pre-era ranging from 1.2-4.3% while post ranged from 22.4-45.6% [Table]. Telemedicine was not used during the pre-COVID-19 era and its use increased to 17.5-23.7% of all visits by organ type during the COVID-era.

Conclusions: The COVID-19 pandemic has accelerated the use of telehealth in all phases and types of solid organ transplantation. The use of telemedicine although increased represents a minority of total visits and the increased use of telephone visits suggest barriers may remain to more widespread adoption of F2F technology that warrant further investigation.

Abstract# 1263

Racial/ethnic and Sex Disparities in Renal Transplant Waitlisting Accounting for Pre-Waitlist Mortality

R. Hamoda[1], R. Patzer[2], M. Saunders[1], *[1]University of Chicago, Chicago, IL, [2]Emory University, Atlanta, GA*

Purpose: The purpose of this study was to assess racial/ethnic and sex differences in access to the renal transplant deceased donor waiting list among incident dialysis patients, accounting for pre-waitlisting mortality as a competing risk.
Methods: After excluding prior renal transplant recipients (n=1,291) and pre-emptive transplants (n=522), we identified a retrospective cohort of all incident adult dialysis patients from January 1, 2015 - December 31, 2016 and followed this cohort through December 31, 2018 via the United States (US) Renal Data System. We used adjusted Fine Gray sub-distribution hazards regression with median imputation to assess racial/ethnic and sex differences in waitlisting accounting for pre-waitlist mortality as a competing risk and adjusting for demographic, clinical and socioeconomic factors.
Results: Among 129,910 US incident dialysis patients, 16.2% (n=20,993) were waitlisted and 26.8% (n=34,814) died before waitlisting. White men (n=42,150, 32.4%) and white women (n=28,293, 21.8%) represented the largest demographic groups among incident dialysis patients, followed by Black men (n=18,200, 14.0%) and Black women (n=15,612, 12.0%). The proportion of waitlisting within each group was highest among Asian men (33.1%) and white men (30.0%), while Black women (17.0%) and white women (14.6%) had the lowest waitlisting proportion. The proportion of pre-waitlisting deaths within each group was highest among white women (58.0%), white men (58.0%), and black women (51.7%), and lowest among Asian males (38.9%). In adjusted analyses accounting for pre-waitlist mortality, Black women (hazard ratio (HR): 0.73, 95% confidence interval (CI): 0.70, 0.77), Black men (HR: 0.82, 95% CI: 0.78, 0.86), white women (HR: 0.86, 95% CI: 0.82, 0.89), and Hispanic women (HR: 0.91, 95% CI: 0.86, 0.96) experienced reduced likelihood of waitlisting compared to white men. (Figure 1).
Conclusions: Racial/ethnic and sex disparities in access to waitlisting for renal transplantation remain after accounting for pre-waitlisting mortality, particularly among female and Black dialysis patients. Notably, Black women appear to experience a compounded disadvantage in access to waitlisting compared to their white female and Black male counterparts. Future work should intervene on improving early access to transplant education, referral, and medical evaluation for these demographic groups.

Abstract# 1264

Are Liver Transplant Center Websites Accessible to All?

C. E. Jacobson[1], R. Olmeda Barrientos[2], M. A. Anderson[3], M. J. Englesbe[3], S. A. Waits[3], V. S. Valbuena[3], *[1]University of Michigan Medical School, Ann Arbor, MI, [2]University Of California – Riverside, School of Medicine, Riverside, CA, [3]Department of Surgery, University of Michigan Health System, Ann Arbor, MI*

Purpose: Ensuring equitable access to transplant center information is an important step in combating health disparities in liver transplantation. This study aimed to assess liver transplant center website readability to determine whether their content was accessible to all patients.
Methods: US liver transplant centers (n=145) were screened by 2019 transplant volume, and the top 14 centers were selected for initial evaluation. The content of each center's liver transplant website was evaluated for readability ease and the education level required to understand the material presented. We used five validated readability tests: New Dale-Chall, Flesch-Kincaid, Flesch Reading Ease, Fry, and Simple Measure of Gobbledygook (SMOG).
Results: The average education level required to comprehend the patient-facing information in this selection of liver transplant center websites was a college undergraduate education. This measure ranged from high school sophomore to doctorate level. On a readability scale of 0-100 (0= most difficult to read, 100= easiest to read), the average website readability ease was 35. Comparable readability and grade-level results were obtained with the additional readability tests performed.
Conclusions: The patient information provided by 14 high volume liver transplant center websites was difficult to read and required an educational level far above the average U.S. national literacy level of 6th-8th grade. We plan to assess the remaining 126 liver transplant center websites and analyze how well they reflect the demographics in their regions based on educational level, race, and alternative languages to English.

Regional Impact of Covid-19 on Kidney Transplant in the Southeast

C. Jay[1], B. Sharda[1], R. Helmick[2], R. Forbes[3], V. Casingal[4], R. Stratta[1], *[1]Wake Forest Baptist Health, Division of Abdominal Organ Transplantation, Winston-Salem, NC, [2]University of Tennessee Health Science Center, James Eason Transplant Institute, Memphis, TN, [3]Vanderbilt University Medical Center, Division of Kidney and Pancreas Transplantation, Nashville, TN, [4]Atrium Health, Division of Transplant Surgery, Charlotte, NC*

Purpose: Despite categorization of kidney transplantation as Tier 3b with guidelines against postponing, the impact of the COVID-19 pandemic has been profound but geographically diverse. We examined the variable impact of the pandemic on local waitlist, mortality, and transplant rates in the Southeast and the potential relationship with local disease burden.

Methods: Using SRTR data, we analyzed changes pre- and post-COVID by individual donation service area (DSA) in the Southeast, and compared this with state COVID case rates and deaths per 100,000 population according to CDC data.

Results: The highest COVID case rates occurred in TN while death rates were highest in MS [Table 1]. The largest declines in new kidney listings post-COVID occurred in ALOB and TNMS (both 38%) with MSOP having the smallest decline (9%) despite a high COVID case rate; SCOP had an increase (14%). Waitlist mortality varied greatly from a high of 80% in NCCM to a 19% decrease in TNMS. Transplant rates decreased in most DSAs, but great variation occurred from a 44% decline in NCCM to a 38% increase in TNMS.

Conclusions: There was large variability in new kidney listing, transplant rates, and waitlist mortality according to DSA in the Southeast. These changes did not directly correlate with COVID case and death rates. These findings suggest a complex interplay between population health disparities, racial demographics and urban vs rural local populations.

Table 1: COVID and kidney waitlist, transplant, & mortality rates in the Southeast U.S. according to donation service area

Donation Service Area	COVID case rate*	COVID deaths*	Change in new kidney listings†	Change in waitlist mortality rate†	Change in waitlist mortality rate†
TNMS (western TN)	4,738	59	↓ 38%	↓ 19%	↑ 38%
TNDS (central/eastern TN)	4,738	59	↓ 31%	↑ 28%	↑ 0.2%
NCCM (western NC)	3,058	46	↓ 20%	↑ 80%	↓ 44%
NCNC(central/eastern NC)	3,058	46	↓ 13%	↑ 16%	↓ 5%
SCOP	3,892	81	↑ 14%	↑ 64%	↑ 29%
MSOP	4,600	120	↓ 9%	↑ 78%	↓ 20%
ALOB	4,518	67	↓ 38%	↑ 4%	↑13%
GALL	4,093	85	↓ 15%	↑ 9%	↓9%

Abstract# 1266

Black Transplant Recipients Reside in the Most Socially Vulnerable Communities

A. C. Killian[1], M. C. McLeod[1], B. Shelton[1], R. D. Reed[1], P. MacLennan[1], H. Qu[1], B. J. Orandi[1], D. Sawinski[2], J. E. Locke[1], *[1]University of Alabama at Birmingham Hospital, Birmingham, AL, [2]Hospital of the University of Pennsylvania, Philadelphia, PA*

Purpose: Racial and socioeconomic disparities in post-transplant outcomes have been described for all solid organ recipients. While the importance of the social determinants of health on transplant outcomes is increasingly recognized, community-level vulnerability among transplant populations is not well understood. The purpose of this study was to describe and compare comprehensive social vulnerability profiles among solid organ transplants recipients.

Methods: The Scientific Registry of Transplant Recipients was utilized to identify adult, deceased donor transplant recipients of either kidney, liver, heart, or lung only between 1/1/2018-12/31/2018. Using the Centers for Disease Control and Prevention's 2018 Social Vulnerability Index (SVI), community-level social vulnerability was defined as the median SVI among census-tracts included in each recipient's zip code. Analysis of covariance (ANCOVA) was performed to determine if SVI differed among transplant types by race, controlling for patient-level characteristics. Tukey-Kramer adjustment for multiple comparisons was used to determine significant differences between transplant types.

Results: 24,566 solid organ transplant recipients were included, of which 54%, 26%, 11%, and 10% received kidney, liver, heart or lung transplant, respectively. SVI varied significantly among the different organ types ($F=194.75$, $p<.0001$). Kidney recipients were found to have significantly higher SVI (e.g. greater social vulnerability; adjusted mean SVI=0.52) compared to liver (adjusted mean SVI=0.47, $p<.0001$), heart (adjusted mean SVI=0.44, $p<.0001$), or lung recipients (adjusted mean SVI=0.44, $p<.0001$). Moreover, black recipients (adjusted mean SVI=0.52) of any organ type had higher SVI in comparison to white (adjusted mean SVI=0.42, $p<.0001$) or other race counterparts (adjusted mean SVI=0.45, $p<.0001$; Figure 1).

Conclusions: Kidney transplant recipients lived in communities with significantly greater social vulnerability compared to other solid organ transplant recipients, while black transplant recipients lived in the most socially vulnerable communities, regardless of transplant type. These data motivate further investigation to understand the interplay between recipients' environments and post-transplant outcomes among all solid organ transplants.

Abstract# 1267

Healthcare Disparities Amongst Dialysis Patients in North Carolina: Decreased Access to Transplant in Lowest Health Rank Counties

D. Leto[1], W. Irish[2], C. Haisch[2], B. Tuttle[2], D. Leeser[2], *[1]Cape Fear Valley Medical Center, Fayetteville, NC, [2]East Carolina University, Greenville, NC*

Purpose: This study measured healthcare disparities amongst the counties in North Carolina with the best compared with counties with the worst healthcare outcomes, specifically the opportunity for dialysis patients in less healthy counties to receive a kidney transplantation compared to patients in healthier counties.

Methods: This is a cross-sectional study, utilizing publicly available data from the Health Cost and Utilization Project State Inpatient Database from 2016. Kidney transplant procedures were identified using the diagnosis-related group code 652 and summarized by County. The number patients on dialysis by county was obtained from the North Carolina Division of Health Service Regulation semiannual dialysis report. Utilizing the Robert Wood Johnson Foundation County Health Rankings, we calculated the prevalence of kidney transplantation (KTx) amongst dialysis patients in the top five healthy verses the bottom five unhealthy rank counties. The proportional surgical ratio (PSR), a measure of surgical disparity, was calculated by dividing the observed number of KTx in the 5 lowest rank healthy counties (LRC) by the expected number of KTx using the 5 healthiest counties (HRC) as the standardized reference. Ninety-five percent confidence interval (CI) for the PSR was calculated using Byar approximation.

Results: In 2016 approximately 1.9 million adults lived in the HRC while approximately 246,854 lived in the LRC. Residents in the LRC are typically older, have less education, have lower income, are more likely uninsured and have higher rates of pre-existing conditions compared to residents in the HRC (Table 1). A total of 1,068 individuals in the 5 LRC were on dialysis (4.3 per 1000 population) compared to 3,264 in the 5 HRC (2.1 per 1000 population, $p<0.0001$). A total of 125 KTx were performed, 19 in the 5 LRC and 106 in the 5 HRC. The rate of KTx in HRC was 32.5 verses 17.9 per 1,000 dialysis-population in the LRC. Using HRC as the reference, the PSR for LRC is 0.55 (95% CI of 0.33, 0.85).

Conclusions: Within North Carolina, the prevalence of dialysis dependent renal failure is nearly 2.5 times higher in LRC areas while the rate of kidney transplantation is 45% lower.

Table 1: Summary of Characteristics of the Lowest and Highest Ranked Health Outcome Counties in North Carolina.

Variable	Lowest Rank Healthy Counties (LRC)	Highest Rank Healthy Counties (HRC)	P value
Mean (SD)	N=5	N=5	
Population, 2016	246,854	1,864,588	
Percent African American	39.1 (12.3)	17.4 (8.4)	0.012
Percent Age 65 or over	16.3 (2.0)	11.5 (2.0)	0.005
Median Household Income	$32,560 ($1,553)	$62,483 ($3,188)	<.001
Uninsured Adults[a]	25.2 (4.3)	19.6 (2.1)	0.034
Percent Adult Obesity[b]	36.6 (3.4)	25.4 (4.6)	0.002
Prevalence Diabetes	15.1 (1.0)	8.7 (0.6)	<.001
Percent Some College[c]	49.3 (5.1)	74.9 (5.4)	<.001

a. Percentage of people under age 65 without insurance
b. Percentage of adults that report Body mass index (BMI) ≥ 30 kg/m²
c. Percentage of adults age 25-44 with some post-secondary education

Abstract# 1268

Knowledge and Attitudes Towards Organ Donation Among Asian Americans in Queens

M. T. Li, G. C. Hillyer, D. W. Kim, K. L. King, S. A. Husain, S. Mohan, *Columbia University, New York, NY*

Purpose: Asian Americans have the lowest organ donation registration rates in the United States (U.S.). We attempted to identify organ donation barriers among Chinese and Korean Americans by assessing their knowledge and attitudes toward organ donation.
Methods: A questionnaire assessing organ donation knowledge and awareness, religious, cultural, and social attitudes toward organ donation was distributed to Chinese and Korean American college students and the general public (18+ years) in Queens, New York between March and November 2019.
Results: Among the 514 participants, 371 (72%) were of Chinese descent and 132 (26%) were of Korean descent and 11 (2.1%) were mixed. The majority of participants were female (n=290, 56%) and born outside of the U.S. (n=321, 62%) living in the U.S. for an average of 13.8 years. Organ donation was recognized as a noble act by the majority (n=482, 94%) of the respondents, but only a minority (n=97, 19%) of the respondents were registered donors. Notably, most (n=266, 64%) of the non-registered respondents expressed willingness to register as an organ donor. Expressed willingness to donate coupled with a low median knowledge score (41%), indicated an opportunity to improve knowledge and awareness about organ donation in this population. The registered respondents had a significantly higher knowledge score (p<0.0001), more positive attitudes (p=0.0008) towards organ donation, and higher altruistic measures (p=0.032) than non-registered respondents. Factors including English language proficiency and greater level of U.S. acculturation (p=0.0038), prior familial discussions about donation (p<0.0001) and blood donation (p=0.002), and personal experience such as knowing other organ donor registrants (p<0.0001) were also associated with donor registration status. Combined measures of religious/spiritual beliefs (p=0.445) were not associated with registration status.
Conclusions: The survey identified a knowledge deficit regarding organ donation among Asian Americans and the need to adopt culturally sensitive strategies such as stimulating family discussions about organ donation and providing educational material that is preferably in their native language.

Abstract# 1269

Patient Perspective of the Implementation of Virtual Medicine in a Post-kidney Transplant Clinic

S. Mann[1], M. Kadatz[1], J. Lan[1], O. Johnston[1], C. Luo[2], *[1]Medicine, Division of Nephrology, University of British Columbia, Vancouver, BC, Canada, [2]Pharmaceutical Sciences, Vancouver General Hospital, Vancouver, BC, Canada*

Purpose: COVID-19 dramatically altered the model of health care delivery for transplant recipients, necessitating the routine use of virtual medicine. This resulted in consequences for patients and providers, with potential changes on the quality and cost of care. In this study, we present survey results examining the patient perspective of virtual follow-up care in a post-kidney transplant clinic across a large geographic area in Canada.
Methods: Kidney transplant recipients followed in a multidisciplinary, post-transplant clinic in Vancouver, Canada were surveyed from April 21, 2020 - June 6, 2020, 4 weeks after the implementation of virtual medicine follow up. The survey included questions on the quality of instructions, ease of connection, quality of interaction with care provider, impact on their experience of care as well as time and cost required to attend clinic.
Results: 46% of the 169 respondents were between the age of 40 and 59, while 34% were over the age of 60. 38% were within the first year following kidney transplant. The majority were satisfied with the virtual follow up model and thought the quality of the care was improved (Fig 1). 70% of respondents reported a transit time of more than 30 minutes to attend clinic, and 34% reported costs of > $30 per visit prior to the implementation of virtual medicine (Fig 2).
Conclusions: Kidney transplant recipients were satisfied with the quality of care provided using a virtual medicine platform in this survey. The use of virtual medicine to provide care for patients decreased personal resources required to attend virtual clinics. Further study is required to determine if virtual medicine is an equally effective follow up modality in this patient population.

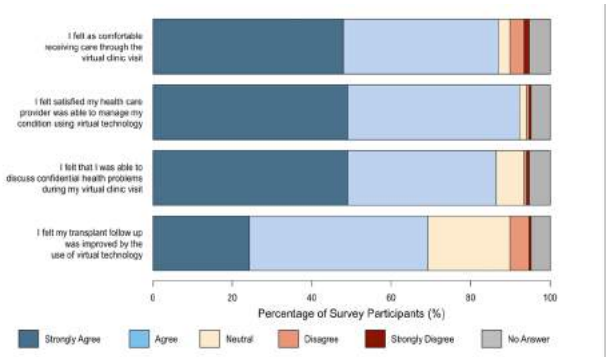

Figure 1: Results of survey describing participants perception of the impact of virtual medicine on the care they received in the post-kidney transplant clinic.

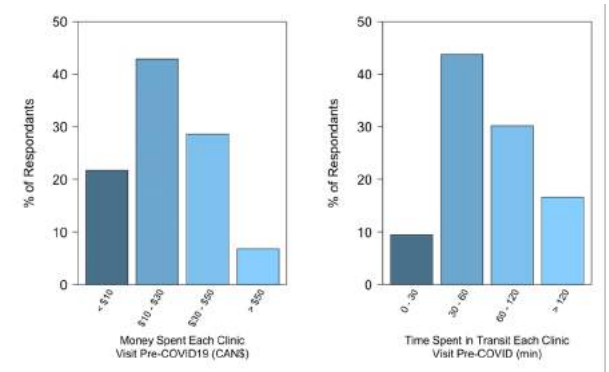

Figure 2: Results of survey describing the time and financial requirements to attend in-person post-kidney transplant clinic visits for before to the implementation of virtual health follow-up pre-COVID-19.

Abstract# 1270

Creating a Culturally Sensitive Report Card for African American Kidney Transplant Candidates: Preliminary Results from Pilot Interviews and Focus Groups

W. T. McKinney[1], M. Bruin[2], B. Kasiske[3], A. Matas[4], A. K. Israni[3], *[1]Hennepin Healthcare Research Institute, Minneapolis, MN, [2]College of Design, University of Minnesota, Minneapolis, MN, [3]Nephrology, Hennepin Healthcare, Minneapolis, MN, [4]Department of Surgery, University of Minnesota, Minneapolis, MN*

Purpose: Racial disparities in kidney transplantation continue to negatively impact African American (AA) patients despite changes to deceased donor allocation practices. AA patients are overrepresented on the waitlist for kidney transplant, face longer wait times, and worse post-transplant outcomes when compared to other communities. Today, AA patients are often unaware of how transplant programs differ and how patient-characteristics influence access to transplant. We aim to evaluate the utility of the patient-specific search of Scientific Registry of Transplant Recipients (SRTR) reports for AA patients, develop a mockup of a culturally sensitive report card, and assess effects the report card has on decision making.

Methods: Pilot interviews and focus groups with AA kidney transplant candidates were structured to collect feedback on the patient-specific search and to inform the development of the culturally sensitive report card (Figure 1). Discussions encouraged participants to consider how the patient-specific search can better serve AA candidates and how to disseminate the tool most effectively to AA patients and stakeholders.

Results: Participant feedback on the patient-specific search was largely positive. Multiple participants indicated that the patient-specific search effectively communicated variations between transplant programs and provided needed information on the availability of specific donor options. At the same time, participants reported that the addition of narratives from AA patients and information on racial disparities would improve the tool's sensitivity to their health needs. Additional themes related to limitations in existing patient education and support practices emerged alongside reflections on the tool and emphasize the potential benefit of improving the accessibility and use of patient-specific tools in consultation with providers and for personal use (Table 1).

Conclusions: Preliminary feedback from pilot interviews identified multiple suggestions for how to improve the accessibility and cultural sensitivity of the patient-specific search. Mock-ups incorporating these suggestions will be evaluated by patients and family members in future focus groups.

Abstract# 1271

Providing Equitable Access: Language and Literacy Levels of Kidney Transplant Center Websites

R. Olmeda Barrientos[1], C. E. Jacobson[2], V. S. Valbuena[3], M. S. Anderson[3], M. J. Englesbe[3], S. A. Waits[3], J. R. Santos-Parker[2], *[1]University Of California – Riverside, School of Medicine, Riverside, CA, [2]University of Michigan Medical School, Ann Arbor, MI, [3]Department of Surgery, University of Michigan Health System, Ann Arbor, MI*

Purpose: Health disparities exist for access to kidney transplantation. Accessibility of patient-facing transplant center resources can contribute to these disparities. Patients interact with transplant centers through multiple interfaces, with online websites being a frequently used resource. It is unknown if these websites provide equitable access to transplant center information. This study aimed to assess kidney transplant center website language and literacy levels.

Methods: US kidney transplant center websites were evaluated for language accessibility. The readability and grade level of each website's content was assessed using the following validated tests: New Dale-Chall, Flesch-Kincaid, Flesch Reading Ease, Fry, and Simple Measure of Gobbledygook (SMOG).

Results: 227 kidney transplant centers' websites were identified. 17% (38/227) provided alternative language resources. Region 4 (OK, TX) and 5 (AZ, CA, NV, NM, UT) provided the most resources (14/57), whereas region 8 (CO, IA, KS, MO, NE, WY) and 10 (IN, MI, OH) did not provide any (0/34). The average readability ease for all websites via the Flesch Reading Ease test was 38±12, ranging from 1 to 69 (0= most difficult to read, 100= easiest to read). The average grade level of reading required to understand online patient information across all kidney transplant websites was college-level education, despite the national U.S. literacy level being between 6th and 8th grade. These results were concordant across the additional tests performed.

Conclusions: Less than 20% of kidney transplant center websites provided alternative language resources, which did not reflect their respective state demographics. Websites' literacy levels are well above the national reading average. We hope to provide recommendations and guidelines to improve transplant center accessibility to patients who are non-English speaking or reading below the national literacy level.

Abstract# 1272

Gray on the Border: A Closer Look at the Gap in Access to Kidney Transplantation for Hispanic Americans

A. Padilla, M. Mujtaba, R. Samper-Ternent, S. Al Snih, N. Perez, J. Fair, R. Kulkarni, E. Polychronopoulou, M. Kueht, *University of Texas Medical Branch, Galveston, TX*

Purpose: Hispanic Americans have disproportionately reduced access to kidney transplantation that is significantly affected by longstanding cultural and geographical disparities. These disparities are multifactorial and include long distances to transplant centers and delayed referral to transplant. To mitigate this lack of access, our center operates multiple clinics across the state including in the Rio Grande Valley (RGV), a region near the Texas-Mexico border.

Methods: The study group comprised all patients evaluated for kidney transplantation between Jan 2015 and Aug 2020 at our institution. Socio-demographic characteristics, comorbidities, and time interval between declaration of ESRD and evaluation were compiled. These data were compared by race/ethnicity and between two clinical sites operated by our institution separated by over 390 miles with distinct population demographics: RGV (border) and MC (main-campus, inland). The proportion of life spent with ESRD prior to evaluation was also calculated.

Results: 2,156 patients were evaluated for kidney transplantation during the study period (RGV: 441, MC: 1723). Four percent of patients at both sites had spent at least 20% of their lives with ESRD prior to evaluation for transplant. A greater proportion of patients at RGV were Hispanic (93% vs 38%, $p<0.01$). Across both sites, Hispanic patients were significantly younger at the time of evaluation (51 vs 56 yrs, $p<0.01$). Time with ESRD at time of evaluation was significantly longer at RGV (3.3 vs 2.7 yrs, $p<0.01$). The proportion of life spent with ESRD prior to evaluation was significantly longer at RGV than MC (6.9 vs 5.7%, $p<0.01$).

Conclusions: Previous analyses of access to transplantation have focused on waitlist and transplant characteristics. This study demonstrated significant differences between both clinics at the beginning of the transplant process, the evaluation. These data support the need for continued efforts to create and maintain access to transplantation in at-risk socio-cultural groups such as Hispanic-Americans.

Abstract# 1273

Racial Differences in Tacrolimus Xr Dosing in De Novo Kidney Transplant Recipients

N. Patel, T. Carcella, F. Bartlett, V. Rohan, D. Taber, *Medical University of South Carolina, Charleston, SC*

Purpose: In May of 2020, our center was challenged with a nationwide shortage of tacrolimus IR, warranting implementation of a new de novo tacrolimus XR protocol. The purpose of this study is to assess two different dosing strategies of Tacrolimus XR in African American (AA) and non-AA de novo kidney transplant recipients.

Methods: This retrospective study includes adult kidney transplant recipients between May 2020 and Sept 2020.The study population was divided into two groups across two different dosing strategies:non-AA and AA and then further stratified based on initial dosing.The initial dosing strategy was to give all patients between 0.12mg/kg and 0.17mg/kg, regardless of race; the second strategy was to give 0.12 mg/kg to non-AAs and 0.15mg/kg to AAs. The primary endpoint was days to a therapeutic tac trough (>7 ng/ml).Other endpoints included dose at steady state (SS), number of doses held, dose at POD 30,time in therapeutic range (TTR) in the first month and adverse effects.

Results: A total of 122 patients were included. There was a statistically higher number of DDKT and DCD in the AA cohort. They also had a significantly higher EPTS score, HLA mismatches, longer time on dialysis, and were more likely to get induction with ATG. In initial analysis, there was a significant interaction between race and dosing strategy for the outcome of time to therapeutic level. During the initial dosing strategy, AA had a significantly longer time to achieving a therapeutic trough (6.2 vs. 4.4 days, P value 0.03). The non-AA group experienced a higher incidence of neurotoxicity compared to the AA group. After the dosing strategy was changed for AA recipients, the time to a therapeutic level decreased to 4 days with no significance between groups. The incidence of neurotoxicity continued to be higher in the non-AA group. The remining results are shown in table 1 and 2.

Conclusions: The results demonstrate that AAs can achieve a similar time to therapeutic tac trough concentrations with tacrolimus XR, as compared to non-AAs, using a race stratified dosing strategy.Future analyses are underway to assess the impact of CYP 3A5 genotype on dose requirements and time to achieve therapeutic levels.

Table 1: Outcomes Pre-dose change (Cohort 1)

	AA (N=57)	Non-AA (N=27)	P-value
Initial mg/kg dose, mean ± SD	0.14 ± 0.03	0.14 ± 0.02	0.390
Initial dose (mg), mean ± SD	12.5 ± 3.9	13.3 ± 4.04	0.329
First therapeutic level by POD 7, N (%)	17 (29.8)	5 (18.5)	0.271
First therapeutic level by POD 5, N (%)	24 (42.1)	7 (25.9)	0.151

Abstract# 1274

Dialysis Staff-Reported Impact of the Early Covid-19 Pandemic on Kidney Transplant Referrals and Evaluations

A. Perez[1], S. Retzloff[1], T. Browne[2], A. Cruz[3], S. Wright[3], S. Pastan[4], R. Patzer[1], *[1]Department of Surgery, Emory University School of Medicine, Atlanta, GA, [2]College of Social Work, University of South Carolina, Columbia, SC, [3]IPRO ESRD Network of the South Atlantic, Morrisville, NC, [4]Department of Medicine, Emory University School of Medicine, Atlanta, GA*

Purpose: COVID-19 has drastically impacted healthcare systems since its declaration as a pandemic in March 2020. Evidence of this impact persists among solid organ transplant programs, with vast disruptions to kidney transplant reported nationwide. Little is known about the influence of COVID-19 on early transplant steps occurring at the dialysis facility level. We sought to describe the staff-reported impact of COVID-19 on kidney transplant referrals and evaluations.

Methods: A cross-sectional survey was emailed to n=579 dialysis facility staff in ESRD Network 6 (Georgia, North Carolina, and South Carolina) in April 2020. Responses were linked to 2015-2018 Centers for Medicare and Medicaid Services Dialysis Facility Report data, and patient and facility characteristics were compared using t-tests, Wilcoxon rank-sum tests, and chi-square tests.

Results: Among 280 survey responses received from unique dialysis facilities, 28.9% of respondents disclosed that transplant referrals were affected by COVID-19, and 60.4% described transplant evaluations as affected (Table 1). When describing barriers to quality improvement activities due to COVID-19, the most prominent concerns were "dependent institutions not operating as usual" (48.6%), an "over-

whelmed healthcare system" (33.6%), and transportation issues (26.8%). Facilities were comparable with regards to patient and facility demographic, clinical, and socioeconomic characteristics.

Table 1. Quality Improvement Activities affected by COVID-19 as reported by dialysis facility staff, 4/13/2020-4/17/2020 (N=280)

Activity	N (%)
Transplant evaluations	169 (60.4)
Hosting/supporting patient support groups	144 (51.4)
Inviting patients to QAPI meetings	141 (50.4)
Vascular access placement	123 (43.9)
Peer Mentor-Mentee interaction	82 (29.3)
Transplant referrals	81 (28.9)
Peer Mentorship training	71 (25.4)
Home dialysis program referral	61 (21.8)
Home dialysis program training (for patients)	42 (15.0)
No area affected	23 (8.2)
Other	13 (4.6)

Conclusions: Our findings provide further evidence that kidney transplant has been substantially affected by the COVID-19 pandemic, even at the dialysis facility level. Policies surrounding transitions to normal operations among dialysis facilities in the Southeastern United States must consider the long-term implications of these delays related to transplant access.

Abstract# 1275

AM PAC Scores and Liver Transplant Resource Utilization

M. Pierpont[1], M. Gosselin[2], K. Robichaux[3], A. Kumar[1], J. Buggs[4], N. Kemmer[5], *[1]Morsani College of Medicine, University of South Florida, Tampa, FL, [2]Honors College, University of Tampa, Tampa, FL, [3]Honors College, University of South Florida, Tampa, FL, [4]Transplant Surgery, Tampa General Hospital, Tampa, FL, [5]Transplant Hepatology, Tampa General Hospital, Tampa, FL*

Purpose: Activity Measure for Post-Acute Care (AM-PAC) is a tool utilized to assess three functional domains: basic mobility, daily activities, and applied cognition. Previous studies have suggested that 6-Clicks, a shorthand form of AM-PAC, strengthens a practitioner's ability to make reliable discharge recommendations and predict hospital length of stay (LOS). The purpose of this study was to examine the correlation between AM-PAC scores (collected by both a physical therapist (PT) and an occupational therapist (OT) to LOS and discharge disposition in liver transplant patients.

Methods: A single-center retrospective chart review was conducted on patients that underwent a liver transplant from May 2019 - May 2020. All pediatric patients were excluded. Resource utilization was defined in the study as LOS and discharge disposition.

Results: Our analysis included data from 128 patient records. Liver transplant alone occurred in 117 patients, while 11 underwent liver and kidney transplants. The mean values for each score were 14.5 (PT AM-PAC score) and 16.8 (OT AM-PAC score). There was a negative correlation between LOS and PT Score (correlation coefficient -0.336, $p<0.001$) and OT score (correlation coefficient -0.398, $p<0.001$). There was a statistically significant difference in the mean score for each of the values based on the patients' disposition at the time of discharge (home vs. rehab respectively). PT AM-PAC score (16 vs 13, $p=0.008$) and OT AM-PAC score (18 vs. 15, $p<0001$).

Conclusions: Our results suggest that lower AM-PAC Scores are associated with higher resource utilization in liver transplant patients. Thus, AMPAC scores may help predict discharge dispositions and length of hospital stay. This is the first study that validates the AMPAC score as a predictor for patient outcomes in transplant therapy.

Abstract# 1276

Survey of Transplantation Providers to Assess for Implicit Bias at a Single Center

C. Ramirez-Sanchez[1], A. Cardenas[2], S. Aslam[1], F. Ferguson[2], M. Vazquez[2], T. Magee[2], K. Mekeel[2], *[1]Infectious Diseases, University of California San Diego, La Jolla, CA, [2]University of California San Diego, La Jolla, CA*

Purpose: At our institution's Center for Transplantation, the Implicit Bias Working Group (IBWG), was formed with the aim to comprehend how implicit biases impact the decision making and treatment of our team members and ultimately our patients; and to develop actionable plans to mitigate bias and promote fair treatment and equitable opportunity for all.

Methods: A confidential and anonymous survey consisting of 21 questions was administered via online Qualtrics instrument to all Center of Transplantation physicians and employees (n=130). This survey assessed for respondent demographics and microaggressions, racism and bias in the work place as well as in the delivery of patient care.

Results: The IBWG provided the opportunity for 100% of staff to complete a voluntary implicit bias training, followed by a confidential survey. Of the 130 surveys delivered, 111 were completed. 56 (48%) of the surveyed team members identified as racial minorities of which, 16 (28%) members have experienced bias and/or discrimination from a team member. Of the 16 who experienced bias and/or discrimination, 10 experienced it *rarely*, 5 *occasionally* and 1 respondent did so *frequently*. More than 40% of the respondents reported having experienced bias and/or discrimination from a patient or patient's family member. These findings demonstrated the undeniable presence of bias and discrimination faced by our team members. While 41% of all respondents noted witnessing some form of bias or discrimination against another team member, only 21% stated they always felt comfortable addressing such issues.

Conclusions: After gaining more understanding of our team members' experience, there will be a focused effort on systematic education and creating a safe forum for identifying, confronting and mitigating implicit bias and its impact on team dynamics. It is imperative that team members are aware of their implicit bias and feel comfortable sharing their thoughts, witnessed events and experiences with the rest of the team and patients to better guide policy, practice, and increase the diversity of the transplant team at all levels to have a positive impact on team dynamics and patient care.

Abstract# 1277

Association of Obesity and Early Post Kidney Transplantation Complications

V. Sandra, N. Sanichar, D. Tsapepas, K. L. King, J. Van Bever, K. Toma, A. Hussain, S. Mohan, *Columbia University Irving Medical Center, New York, NY*

Purpose: Although the prevalence of obesity among kidney transplant recipients is rising, there continues to be reluctance to waitlist obese candidates. We sought to determine the association between recipient body mass index (BMI) and early post-transplant complications.

Methods: Single-center, retrospective cohort study of all adult kidney transplant recipients from 2004-2020. Recipients were stratified into four BMI (at transplant) categories: normal-weight (BMI 18.5-24.9kg/m^2, n=1020), overweight (BMI 25-29.9, n=1002), moderately obese (BMI 30-34.9, n=510), and severely-to-morbidly obese (BMI ≥35, n=274). Logistic regression was used to estimate the association between BMI category and surgical-site infections (SSIs), hydronephrosis, and allograft survival.

Results: Recipients with BMI≥35 had significantly higher rates of SSIs ($p<0.001$) and hydronephrosis ($p<0.001$) compared with recipients in all other BMI categories. On multivariable analysis, recipients with BMI≥35 had increased odds of SSIs compared with normal-weight recipients (odds ratio [OR], 3.3, 95% CI 1.6-7.2, $p=0.022$), and recipients with BMI 30-34.9 and ≥35 had increased odds of early hydronephrosis (OR 1.9, 95% CI 1.1-3.2, $p=0.015$, and OR 2.3, 95% CI 1.2-4.2, $p=0.009$, respectively). While no BMI groups experienced increased odds of allograft failure, recipients who were Black, diabetic pre-transplant, and experienced delayed graft function were at increased odds on multivariable analysis. When the highest BMI group was further stratified into 39.9 and ≥40 kg/m^2 on sensitivity analysis, both groups remained significantly associated with an increased odds of surgical site infections (OR 3.2, 95% CI 1.4-7.3, $p=0.047$, and OR 3.7, 95% CI 1.3-10.6, $p=0.014$) compared to the normal weight group.

Conclusions: Obesity is associated with an increased risk of immediate post-transplant complications such as SSIs and hydronephrosis, but is not associated increased long term risk of kidney allograft failure.

BMI group (kg/m²)	Adjusted OR	95% CI	P
Surgical site infection*

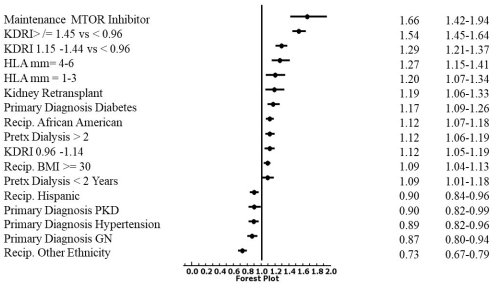
Abstract# 1278

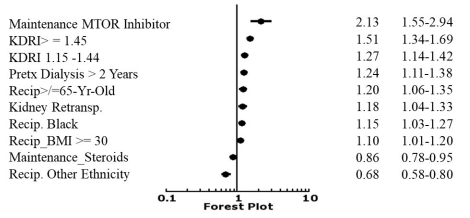
Hospitalization in the First Year After Kidney Transplantation: Analyses to Identify Common Predictors of Risk Across Recipient Sensitization Groups

A. Santos, E. Bueno, M. A. Leghrouz, *University of Florida, Gainesville, FL*

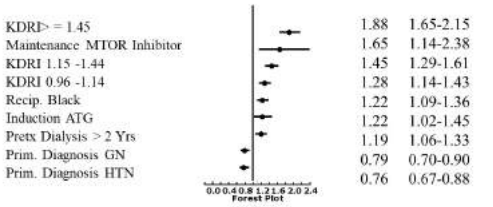
Purpose: We investigated the risk of hospitalization associated with baseline risk factors in adult deceased donor (DD) kidney transplant (KT) recipients (KTRs) stratified into calculated panel reactive antibody (CPRA) groups.
Methods: Using OPTN data, we compared the 1-yr. post-kidney transplant likelihood of hospitalization in adult DDKTRs categorized as low, intermediate, and high sensitization cohorts; corresponding to CPRA levels of <10%, 10%-79%, and >/=80%, respectively. Subsequently, we analyzed the association of baseline risk factors with the likelihood of hospitalization in the year following KT using a logistic regression model for each of the 3 cohorts.
Results: Hospitalization risk factors common to all 3 CPRA groups were: high kidney donor risk index (KDRI-Rao), mammalian target of rapamycin inhibitor (MTORI) immunosuppression, African American KTR ethnicity, and pre-transplant dialysis duration >2 years (**Figs. 1-3**). Across CPRA cohorts, KDRI-Rao >/=1.45 and MTORI regimen carried the highest risks (51%-88% and 65% -113%, respectively) of post-KT hospitalization (**Figs. 1-3**). Anti-thymocyte globulin induction is associated with higher risks of hospitalization than alemtuzumab [HR=1.08; 95% CI=1.02-1.16], (not shown in figures) and interleukin-2 receptor antagonist [HR=1.22; 95% CI=1.02-1.45], (**Fig. 3**) in the low and high sensitization cohorts, respectively.
Conclusions: The risk of first post-transplant year hospitalization may be predicted from risk factors known at the time of or at discharge after DDKT. Closer follow-up of KTR at risk may help prevent re-hospitalizations and associated adverse outcomes.



Risk Factors for All-Cause Hospitalization, First Year Post Kidney Transplant
CPRA <10% Group



Risk Factors for All-Cause Hospitalization, First Year Post Kidney Transplant
CPRA 10-79 % Group



Risk Factors for All-Cause Hospitalization, First Year Post Kidney Transplant
CPRA >/= 80 % Group

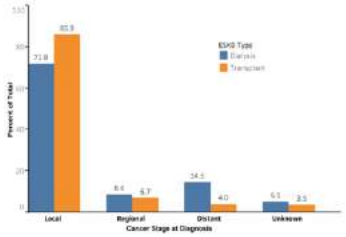
Abstract# 1279

Prostate Cancer Mortality is Not Worse Among Kidney Transplant Recipients Compared to Dialysis Patients

N. Sarabu[1], W. Dong[2], S. M. Koroukian[2], *[1]University Hospital Cleveland Medical Center, Cleveland, OH, [2]Case Western Reserve University, Cleveland, OH*

Purpose: Recent recommendations from expert panel of American Society of Transplantation (AST) state that most patients with prostate cancer (PCa) do not need to wait additional time, due to PCa, for kidney transplant (KT) even though there is limited data on how post transplant outcomes compare to dialysis patients with PCa.
Methods: Utilizing Surveillance Epidemiology End Results (SEER)-Medicare registry data, we retrospectively studied ESKD (dialysis and kidney transplant) patients (≥40 years old), who were diagnosed with prostate cancer between January 1, 2004 and September 30, 2015 after established ESKD diagnosis. Distribution of stage at diagnosis was compared between dialysis and KT using chi-square test. Time to all-cause death (OM) and time to death due to PCa (CS), by stage at diagnosis were compared using Kaplan-Meier, Cumulative Incidence Function, Cox-proportional hazards and Fine-Gray competing risk models.
Results: A total of 1959 patients met our eligibility criteria (1478 on dialysis and 481 with functioning KT). KT patients were more likely to present with local stage and less likely to present with distant stage at diagnosis than dialysis counterparts

Figure 1: Distribution of ESKD Patients With PCa (2004-2015), by Dialysis Vs. KT.



In the multivariable models, KT had 45% lower hazard of OM ($_{0.46}0.55_{0.66}$) and no difference in CS ($_{0.42}0.68_{1.11}$). Patient characteristics that were associated with worse CS included regional and distant stage at presentation, Gleason score >8, and PSA level > 20

Table 1: Selected Multivariate Associations of Overall Mortality and Prostate Cancer Specific Mortality for ESKD (dialysis and KT) Patients (2004-2015)

Variable	Adjusted Hazard Ratio for Overall Mortality, aHR (95%CI)	Adjusted Hazard Ratio for Prostate PCa specific Mortality, aHR (95%CI)
Stage		
Regional Vs. Local	**1.35 (1.07, 1.69)**	**3.04 (1.75, 5.28)**
Distant Vs. Local	**2.88 (2.31, 3.59)**	**6.20 (3.81, 10.10)**
Age at Diagnosis (%)		
65-74 Vs. 40-64	**1.52 (1.30, 1.77)**	1.15 (0.74, 1.78)
75+ Vs. 40-64	**2.15 (1.79, 2.59)**	1.35 (0.83, 2.20)
ESKD Type		
Kidney Transplant Vs. Dialysis	**0.55 (0.46, 0.66)**	0.68 (0.42, 1.11)
Gleason Score		
≥8 Vs. < 8	**1.23 (1.05, 1.44)**	**2.77 (1.76, 4.37)**
PSA Level		
>20 Vs. ≤20	1.07 (0.90, 1.28)	**1.71 (1.06, 2.75)**

Interestingly, receiving surgery or radiation was not associated with improvement in CS ($_{0.67}0.95_{1.36}$).

Conclusions: Our study shows that, compared to dialysis patients, kidney transplant recipients with prostate cancer have almost two times better overall survival but similar prostate cancer specific survival. Moreover, receiving surgery or radiation for prostate cancer is not associated with improved prostate cancer specific survival. These findings support the recent recommendation made by AST expert panel that for kidney transplant candidates with prostate cancer, no waiting prior to transplant or treatment for prostate cancer is necessary for localized and regional stages.

Abstract# 1280

Seeing is Believing: Efficacy of a Video-based Intervention in Improving Awareness of Skin Cancer Risk for Solid Organ Transplant Recipients

E. Shah[1], S. Michalak[1], R. Haughton[1], B. Fernandez[1], I. Ahronowitz[2], *[1]Keck School of Medicine, Los Angeles, CA, [2]Dermatology, Keck School of Medicine, Los Angeles, CA*

Purpose: Our research focuses on the efficacy of using a novel video-based intervention to educate solid organ transplant recipients on their increased risk of skin cancer. I will be referring to solid organ transplant recipients as SOTR in this abstract.

Methods: In this ongoing prospective study, SOTR from our majority-Hispanic patient population at Los Angeles County Hospital and Keck Hospital of USC seen by our dermatology department were enrolled. Participants completed a pre-intervention survey measuring their perceived risk of developing skin cancer and their sun protective behaviors. We developed an informational video in English and Spanish highlighting the increased risk posed to transplant recipients in developing non-melanoma skin cancer and preventive strategies, including sunscreen, protective clothing, self-skin checks, and dermatology follow ups. After viewing the video, patients were completed a post-intervention survey to see if their perceptions and practices regarding skin cancer had changed.

Results: A total of 48 SOTR patients were enrolled in the study. We analyzed the results 13 patients who completed both in the pre- and post- intervention survey. As shown in Figure 1, 69% of patients reported sunscreen use pre-intervention compared to 92% of patients post-intervention. In addition, 46% of patients reported an improved understanding of their skin cancer risk pre-intervention compared to 77% of patients post-intervention and 54% of patients had checked for skin cancer in the past month pre-intervention compared to 69% of patients post-intervention. Of the 48 enrolled participants, 58.8% identified as Hispanic or Latino, however of the 13 who completed the post-intervention surveys only 15.4% identified as Hispanic or Latino. We are currently enrolling more patients in hopes of achieving a more representative demographic breakdown.

Conclusions: Our study builds on prior literature which demonstrates the efficacy of video-based messaging and intervention on behavior change to reduce the risk of skin cancer in the general population as well as in SOTR. This intervention presents a cost-effective and timely method to increase awareness of skin cancer for at-risk patients. In addition, the discrepancy of Hispanic and Latino patient enrollment pre and post intervention highlights the need to address how to improve study retention of minority patients.

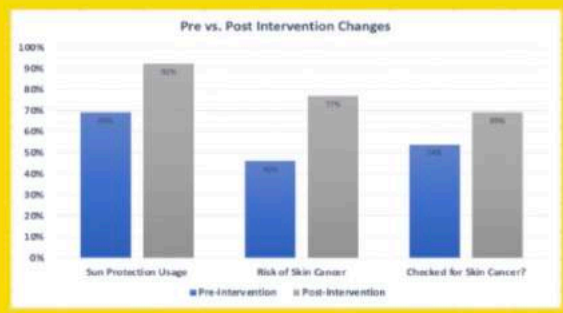

Figure 1. Survey response changes pre vs. post intervention. A) Percent of patients answering yes to use of suncreen, B) Percent of patients who perceive themselves as at elevated risk for skin cancer, C) Percent of patients who self check for skin cancer

Abstract# 1281

Increased Deceased Organ Donation Rates Among Racial and Ethnic Minorities: Not Exactly. A UNOS/NHSBT UK Donor Data Analysis Over the Last Five Years

H. Sharma[1], A. Pradeep[2], A. Ditchfield[3], M. Abraham[4], P. Lominchar[5], S. Mehra[1], A. Skaro[4], *[1]Transplant and Vascular Access Surgery, Royal Liverpool University Hospital, Liverpool, United Kingdom, [2]Liver Unit, King's College, London, United Kingdom, [3]Transplant and Vascular Access Surgery, Manchester Royal Infirmary, Manchester, United Kingdom, [4]Transplant Surgery, University Of Western Ontario, London, ON, Canada, [5]Visceral Surgery, Hospital General Universitario Gregorio Marañon, Madrid, Spain*

Purpose: The recent reports suggest that organ donation from minority population have been increasing. The comparative organ donation data from the minority population reported to UNOS/NHSBT over the last five years was data mined.

Methods: Deceased Organ donation figures from 2014/15-2019/20 were analysed. The percentage trends and organ donation probabilities of all donor groups were calculated.

Results: Total numbers of total deceased organ-donations have increased in USA (N=9079 in 2015, N=11870 in 2019) and UK (N=1298 in 2015, N=1454 in 2019). There has been an increase in donations from minorities (USA N=3113 in 2015, N=4087 in 2019; UK N=80 in 2015; N=121 in 2019). In USA, % share of organ donation from minorities has been nearly constant at approx. 33-34% , in UK the % share has marginally improved from 6.2 % in 2015 to 7.3% in 2019.

Despite the increase in total numbers, the Delta-Δ change in organ-donation from minorities compared to total organ-donation volume has shown a negative trend compared to the previous years (USA 0.72% in 2015, --0.21%in 2019; UK 0.40% in 2015; 0.32% in 2019).

Population and viewpoints of minority-populations are different in both countries, yet religious/cultural beliefs are the commonest reasons for a family declining donation.

Conclusions: Despite a marginal increase in donation numbers, the overall organ-donation from the minority-population is still low and has not kept in pace with total-donation volumes. The minority population needs more administration initiatives and education to improve organ donation.

Abstract# 1282

Has the Proportional Rise in Deceased Organ Donation Rate Over Last 5 Years Been Optimal? A Data-based, Forecasting Model Analysis of UNOS/NHSBT UK Donor Data

H. Sharma[1], A. Sharma[2], *[1]Transplant and Vascular Access Surgery, Royal Liverpool University Hospital, Liverpool, United Kingdom, [2]Data Analytics, Loyola University, Chicago, IL*

Purpose: The increase in deceased donor numbers since last decade has been widely reported. We aim to analyse if the trend in rise of numbers has been optimum as per the forecasting casting model based on historical organ procurement data from UNOS/NHSBT UK from 2005-2014.

Methods: We created a Forecasting model using exponential moving average method for time-series forecasting . We compared the forecasted figures to the actual deceased donor numbers for last 5 years (2015-2019) . We also compared the forecasted versus actual donation rates in the minority population group.

Results: The total actual versus forecasted deceased donation rates in US have kept pace p=0.46. In 2019, the actual donation numbers were in excess of forecasted digits but the actual donation rates in minority population in US have shown a negative trend compared to the forecasted figures p=0.002. In the UK, the actual donation rates were inferior compared to the forecasted numbers p=0.02. The actual organ donation rates were sub optimal in minority population p=0.007.

Conclusions: The actual total deceased organ donation rates in US exceed the forecast but fall in actual donation from minority population compared to forecasted figures indicates failure of social initiatives. The UK actual total and minority population deceased organ donation trends have fallen behind the forecasted figures. More creative initiatives are needed to involve the minority population to improve the numbers.

Abstract# 1283

Outcomes of Patients Referred for Liver Transplant Evaluation

E. Solomon[1], M. Waykar[2], K. Robichaux[3], J. Buggs[4], A. Kumar[1], N. Kemmer[5], *[1]Morsani College of Medicine, University of South Florida, Tampa, FL, [2]Honors College, University of Tampa, Tampa, FL, [3]Honors College, University of South Florida, Tampa, FL, [4]Transplant Surgery, Tampa General Hospital, Tampa, FL, [5]Transplant Hepatology, Tampa General Hospital, Tampa, FL*

Purpose: National demand for liver transplants is increasing steadily, with 8,896 liver transplants performed in the USA in 2019, a 7.8% increase from 2018. The number of patients being waitlisted for liver transplant has also increased, with 12,106 waitlisted as of 11/2020. Our own transplant center saw an increase in the number of transplants from 78 (2018) to 145 (2019). The purpose of this study was to evaluate the number and location of liver transplant evaluations in a growing liver transplant program with increased volumes of patient referrals and the utilization of a transitional care clinic.

Methods: We included all adult patients referred for transplant evaluation at our center from 2018-2019 in our electronic medical records. The data was analyzed in SPSS, with significance testing performed with Fisher's exact and Pearson's chi-squared tests. A p-value of less than 0.05 was considered significant. For patients with multiple evaluation encounters, only the most recent encounter was used for analysis. For patients with multiple transplants, only the first encounter was used.

Results: There was an increase in the number of referred patients from 299 (2018) to 371 (2019). The duration from referral to evaluation decreased from 30 days (2018) to 21 days (2019), p<0.001. We found significantly decreased waitlist mortality, with 16 deaths in 2018 vs. eight deaths in 2019, p=0.035. The location of the evaluation initiation (in-patient vs. out-patient) differed from 2018 (69 in-patient vs. 230 out-patient) compared with 2019 (127 in-patient vs. 244 out-patient), p=0.002. There were significant differences in the social evaluation results with an increase in the number of incomplete evaluations (47 vs. 96) and the number of higher risk evaluations (48 vs. 84) in the two respective years of the study, p=<0.001. Lastly, there were differences in the number of psychological evaluations not completed in 2018 (53) vs. 2019 (172), p=0.001.

Conclusions: We observed statistically significant decreases in important metrics including waitlist mortality and referral to evaluation time. This is despite an increase in the number of patients deemed intermediate to high social risk, as well as an increase in the number of candidates seen initially as inpatients. The observed results correspond with the implementation of a transitional care clinic in January 2019, which provides two-week follow-up after inpatient admission and continuous outpatient monitoring. We hypothesize this clinic played a role in managing the higher load of inpatient transplant candidates and transitioning them to outpatient evaluations, producing the observed decrease in waitlist mortality and likely reducing costs.

Abstract# 1284

Equity in Access to Kidney Transplants by Race/ethnicity in the Covid-19 Era

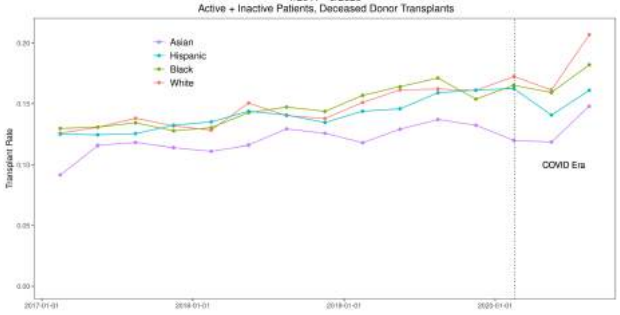
D. Stewart[1], A. Robinson[2], K. Bradbrook[2], A. Wilk[2], D. Klassen[3], *[1]United Network for Organ Sharing, Richmond, VA, [2]Research, United Network for Organ Sharing, Richmond, VA, [3]Chief Medical Officer, United Network for Organ Sharing, Richmond, VA*

Purpose: The direct impact of the COVID-19 pandemic on minority populations has been well documented, and it is conceivable that disparities in access to kidney transplants by race and ethnicity have been exacerbated during the pandemic. Barriers to transplant may have emerged due to concerns about increased susceptibility to COVID-19 among racial/ethnic minorities.

Methods: We examined quarterly trends in deceased donor kidney transplants per patient-year on the waiting list over time (1/2017-9/2020) among 4 major racial/ethnic groups (White; Black; Hispanic; Asian). Unadjusted and adjusted Poisson regressions were used to estimate transplant rates pre-COVID-19 (1/2019-3/2020) and during COVID-19 (4/2020-9/2020). In addition to race/ethnicity, adjusted models included 17 factors such as blood type, CPRA, age, gender, diagnosis, and transplant center. Median KDPI was calculated among recipients.

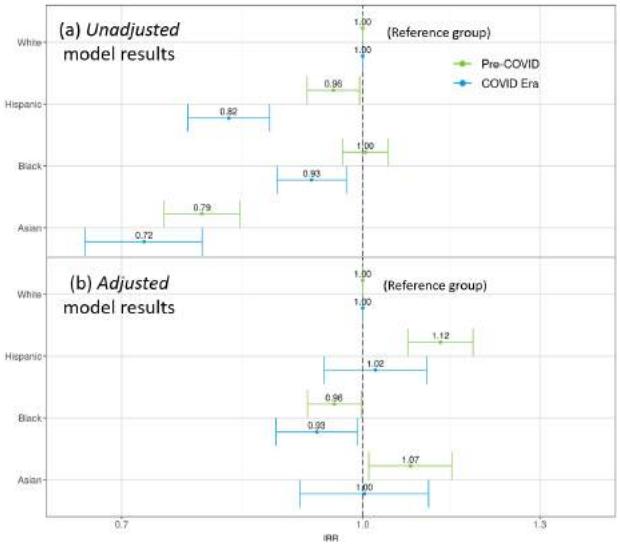
Results: For all 4 racial/ethnic groups, transplant rates rose steadily prior to COVID-19, declined initially during the pandemic, and rebounded sharply in Jul-Sep '20. However, the decline was sharpest for Hispanic candidates, and the COVID-19-era rebound was greatest for White and Asian candidates (Fig 1).

Figure 1. Kidney Transplant Rates - Quarterly Time Trends by Race/Ethnicity
1/2017 - 9/2020
Active + Inactive Patients, Deceased Donor Transplants



Relative to Whites, the transplant incidence rate ratio (IRR) declined in the COVID-19 era for minorities (race by era interaction, p=0.0006, Fig 2a). Racial/ethnic transplant rate differences, and the race by era interaction, were both substantially attenuated in risk-adjusted modeling (Fig 2b). Median KDPI remained unchanged or improved during the pandemic for both White and minority recipients.

Figure 2. Deceased Donor Kidney Transplant Incidence Rate Ratios by Race
Among Active + Inactive WL Candidates
Pre-COVID (1/2019-3/2019) vs. COVID Era (4/2020-9/2020)



Conclusions: Remarkably, the overall transplant rate surpassed pre-pandemic levels, as the transplant community has adapted remarkably well to the pandemic. But early COVID-19-era data suggest racial/ethnic disparities may have increased, particularly for Hispanic candidates. As the community continues to adapt and plan for the possibility of further pandemic impact, practices to ensure safe and equitable access to transplantation for vulnerable groups should be further developed and disseminated.

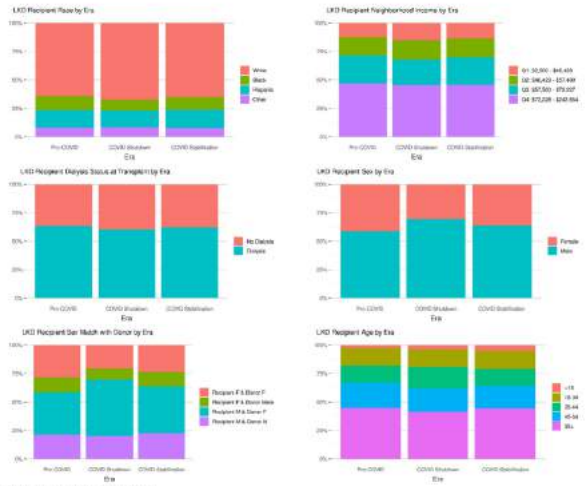
Abstract# 1285

Impact of COVID-19 Crisis on Disparities in Living Kidney Donation in the US

J. Wainright, S. Booker, J. Foutz, A. Henderson, R. Goff, L. Cartwright, D. Klassen, *Research, UNOS, Richmond, VA*

Purpose: The COVID-19 pandemic resulted in a dramatic decrease in living kidney donation (LKD) in the U.S. This study investigated the effect of the COVID crisis on characteristics of LKD recipients in the U.S.
Methods: We used OPTN transplant and LKD data to compare proportions of LKD recipients' race, SES (neighborhood income), sex, dialysis status, age, and recipient/donor sex match during 3 eras: Pre-COVID (1/1/20-3/12/20, n=1294); COVID Shutdown (3/13/20-5/9/20, n=173); and COVID Stabilization (5/10/20-11/15/20, n=2331; Table 1).
Results: Contrary to our expectations, LKD recipients' race, neighborhood income, and dialysis status at transplant did not differ by era (Figure 1a-c; Table 2). We did, however, find a significant relationship between recipient sex and era, with a higher proportion of male recipients in the COVID Shutdown and COVID Stabilization eras than in the Pre-COVID era (Figure 1d). We found a related significant association between recipient/donor sex match and era, with a higher proportion of male-recipient/female-donor transplants and a lower proportion of female-recipient/female-donor transplants in the COVID Shutdown and COVID Stabilization eras than in the Pre-COVID era (Figure 1e). There was a marginally significant relationship between recipient age at transplant and era, with a higher proportion of younger recipients in the COVID Shutdown era than in the Pre-COVID and COVID Stabilization eras (Figure 1f).
Conclusions: While we did not find expected differences in areas of current disparities such as LKD recipient race or SES, we did find that the drop in living donation caused by the COVID crisis exacerbated previously existing disparities in recipient sex and recipient/donor sex match, suggesting that COVID has not had an equal effect on all candidates.

Figure 1. Living Kidney Donor Recipients' Characteristics by COVID Era



Pre-COVID: 1/1/20-3/12/20
COVID Shutdown: 3/13/20-5/9/20
COVID Stabilization: 5/10/20-11/15/20

Abstract# 1286

Body Mass Index >35 Does Not Impact Kidney Transplant Outcomes or Health Related Quality of Life Despite BMI Class or Recipient Race

D. A. Walczak[1], E. Collins[2], E. Benedetti[1], *[1]Organ Transplant, University of Il Hospital and Health Sciences System, Chicago, IL, [2]College of Nursing, Dept of Bio-behavioral Health Science, University of Illinois at Chicago, Chicago, IL*

Purpose: Kidney transplant [KTx] in recipients with BMI ≥ 35 remains controversial and has not often been studied in recipients with BMI ≥40. There is limited data as to whether health related quality of life [HRQOL] is adversely affected by being obese after KTx. This ambi-directional study examined the relationship between degree of obesity, KTx outcomes and HRQOL, across BMI and racial groups.
Methods: Medical records of 227 low risk, adult, KTx recipients with BMI ≥ 30, transplanted between 1/2009 & 10/2017 were retrospectively reviewed. A prospective approach allowed a 1 time HRQOL assessment for those who had not yet completed a Kidney Disease Quality of Life-36 [KDQOL-36] survey post KTx. The cohort was stratified into four obese groups: BMI 30-34.9, BMI 35-39.9, BMI 40-49.9 and BMI ≥ 50. Demographics included age, race, gender, education years and zip code. Also included were number of years post KTx, dialysis years, donor source, surgical approach, history of diabetes [DM], hypertension [HTN] or vascular disease, serum albumin at KTx, and longterm use of steroids or mTOR inhibitor. Outcome measures included patient and graft survival, serum creatinine and glomerular filtration rate at 1, 3 and 5 yrs, acute rejection, delayed graft function, and wound complications.

KDQOL-36 component scores were used to measure HRQOL and were compared to U.S. normative KDQOL-36 values. BMI was recorded at KTx, at KDQOL-36 survey and at study end. *P* values ≤ 0.05 were considered significant.
Results: Mean follow up was 4.5 yrs [± 2.76]. Overall, 61% of study participants were Black and 57% received living donor organs. Demographics were similar across BMI groups. Patient & graft survival reached 100% at 1 yr in all BMI groups, was above the current national average at 1 & 3 yrs, and was not significantly different at 3 or 5 yrs. Females had a .1512 [p=0.013] increase in patient survival and race did not negatively affect outcomes. A history of DM was associated with increased BMI [p=0.027] and correlated [r=0.2] with a 3.4% [p=0.0288] increase in death risk. Although age ≥ 51yrs [p=0.000], female gender [p=0.057] and DM [p=0.020] significantly decreased KDQOL-36 physical component scores, all KDQOL-36 component scores were at or above the normative scores for the US dialysis population. Importantly, BMI class had no significant effect on HRQOL.
Conclusions: KTx for those with BMI ≥ 35 offered graft and patient survival and HRQOL above the US normative average for transplant recipients and patients on dialysis. Obesity should not be an absolute contraindication to KTx regardless of race or degree of BMI. However, a history of DM can predict poorer recipient survival and lower HRQOL physical component scores in obese recipients, suggesting a need for rigorous DM management pre and post KTx.

Abstract# 1287

Improving Well-being for Heart Transplant Recipients: Implementation of a Patient Navigator Program

K. Ramonas, K. Ramonas, *Health Navigator Foundation, San Francisco, CA*

Purpose: When surveyed, heart transplant recipients cited managing all their healthcare needs as a primary concern 83% of the time (n=23). To respond to this need, a patient navigator program was created. We aim to show that providing individualized navigator services following discharge from the hospital post heart transplant improves well-being for recipients.
Methods: All heart transplant recipients at a single center, identified prior to discharge, were eligible for enrollment and offered navigation services. The program provides individualized interventions for 4-6 weeks following hospital discharge, at no additional cost to recipients. Services provided include: immediate phone, email, or HIPAA compliant text access to a patient navigator team, personal escort to lab draws, tests and procedures, and navigator accompaniment to outpatient appointments. The navigator program also provided: medication organizers, vital sign and symptom log, meal delivery, local resource guide, caregiver support, translation services, social work support, peer networking, and community resource referrals. Average navigator time dedicated to each patient varied but ranged 1-4 hours/week. All recipients completed a pre- and post- enrollment quality of life survey as well as an exit interview about program services. We utilized the organ transplant symptom and well-being instrument (Forsberg, et al., 2012)
Results: In this pilot study, 23 patients enrolled in the program over an 18 month period and completed a pre program survey. 19 recipients completed a post program survey after receiving navigation services. Pre program, the average quality of life reported was 47 on a 100 point scale. 78% of respondents reported they could not complete desired activities. Post program, 100% of patients reported their quality of life to be better than expected. 78% believed the program contributed to their success. 90% of participants would recommend the program to others.
Conclusions: Results from this pilot suggest a positive impact of the patient navigator program in a heart transplant recipient population, particularly in its ability to meet individual needs and immediate access to a team member. Future work with a larger sample size is indicated to more fully assess the program's impact on quality of life. Preliminary data suggest implementation of a patient navigator program contributes positively to heart transplant recipients' health and well-being. Individualized navigation programs could be effective in improving well-being for a wide range of patients with critical illnesses.

Abstract# 1288

Genetic versus Self-reported African Ancestry and Kidney Allograft Outcome: Analysis of Two Large Multiethnic Urban Transplant Cohorts

F. Zanoni[1], D. Neugut[1], S. Mohan[1], A. Gharavi[1], B. Keating[2], K. Kiryluk[1], *[1]Department of Medicine, Division of Nephrology, Columbia University, New York, NY, [2]Department of Surgery, Division of Transplantation, University of Pennsylvania, Philadelphia, PA*

Purpose: African-American (AA) kidney transplant recipients (KTx) have higher risk of rejection and failure. However, it is unknown to what extent the inferior outcomes in self-reported AAs are due to genetic versus environmental effects. Herein, we compared the effects of self-reported race versus genetic African admixture on graft outcomes.
Methods: A discovery multiethnic cohort of 1,083 KTx from Columbia University and a replication cohort of 761 kidney transplant recipients from University of Pennsylvania were genotyped with high resolution SNP arrays. African admixture proportions (AFR), a genetically-derived quantitative measure of African ancestry, was estimated with ADMIXTURE software. US census tract variables matched with participants' geocoded addresses were used to analyze the effect of neighborhood socio-economic status (SES) factors. Multivariable Cox models were used to investigate associations between African ancestry measures and time to biopsy-proven rejection and time to death-censored graft failure, with adjustments for relevant covariates. Akaike information criterion (AIC) was used to compare the models. Meta-analyses of the results in the two cohorts were computed using random-effect models.
Results: 206 and 346 self-identified AA were included in the discovery and replication cohorts, respectively. Over a median time of 78 months, 432 patients had rejection and 193 had graft failure in the discovery cohort; during a median time of 49 months, 113 patients had rejection and 121 had failure in the replication cohort. In the discovery and replication cohorts self-reported AA ancestry and AFR were associated with acute rejection and graft failure (Figure 1). AIC values show that AFR is non-inferior or slightly better predictor than self-reported AA. The HR for measures of ancestry only mildly decreased when adjusting for SES factors in both cohorts. Meta-analyses of the results confirmed that self-reported AA and AFR were associated with rejection and failure independently of clinical covariates and SES.
Conclusions: In conclusion, self-reported AA race and a genetically-derived continuous measure of African ancestry predict the risk of allograft rejection and failure in multiethnic and genetically diverse cohorts. A composite variable for US census-derived neighborhood SES did not confound the association between ancestry and either rejection or failure.

Wound Infection After Kidney Transplantation: A Single Center Study

A. Demirag, J. Oberholzer, A. Agarwal, B. Rawashdeh, E. McCraken, K. Brayman, *Transplantation, University of Virginia Medical Cener, Charlottesville, VA*

Purpose: Wound complications (WC) following kidney transplantation (KTx) consume valuable resources and may be associated with inferior short and long term graft outcomes. Known risk factors for WC include immunosuppression(IS) exposure, diabetes(DM), and obesity, as measured by body mass index (BMI). In this study, we sought to identify surgical and non-surgical factors associated with the development of WC following KTx.
Methods: 741 consecutive patients received KTx at a single center over a 6 year period and were retrospectively reviewed. Combined transplantations and children (< age 18) were excluded. Recipients were classified based on BMI at the time of transplantation: underweight (BMI < 20 kg/m2), normal weight (20 ≤ BMI < 25), overweight (25 ≤ BMI < 30), class I obese (30 ≤ BMI < 35), class II obese (35 ≤ BMI < 40) and class III obese (BMI ≥ 40). The analysis included wound (superficial or deep) or organ space infection and its association with age, gender, HLA mismatch, cold ischemic time, hypertension, DM, delay graft function and surgical technique (open versus robotic transplant(RT)). Statistical analysis was performed by SPSS and significance was set at $p<0.05$. All patients received a single dose of pre-operative antibiotic prophylaxis and thymoglobulin for induction (3-6 mg/kg). IS was administered based on transplant center protocol and maintenance IS consisted of prednisone, prograf and mycophenolate.
Results: Thirteen percent (94/741) of patients developed a post-transplant WC (28±16 days postop), 46% (43/94) of these were superficial-incisional and 54% (51/94) were deep-incisional or organ-space. The average BMI among cohort patients was 29.2 and 42% (311/741) were obese (BMI > 30) (table) Patients who developed WC had a greater mean BMI (31.4 vs 29.4, p =0.004) and were more likely to have

a history of DM (33 vs. 49%, p<0.05). RT recipients (n=39, mean BMI 39.5±4.2) showed significantly lower WC rates compared to the whole study group and group with BMI over 30(mean BMI 34±3.8) (p<0.00).

Conclusions: We identified higher BMI and DM as a risk factor for the development of WC following renal transplantation. RT was successful at lowering the higher WC infection rate in diabetic and high BMI patients.

Abstract# 1290

The Impact of Thromboelastography on Decreasing Blood Product Usage in Liver Transplantation

A. Mohamed[1], T. Kitajima[1], S. Angappan[2], K. Delvecchio[1], A. M. Elsabbagh[1], S. Yeddula[1], M. Shamaa[1], K. Collins[1], M. Rizzari[1], A. Yoshida[1], M. Abouljoud[1], J. El-Bashir[2], S. Nagai[1], *[1]Department of Transplant and Hepatobiliary Surgery, Henry Ford Hospital, Detroit, MI, [2]Department of Anesthesiology, Henry Ford Hospital, Detroit, MI*

Purpose: Liver dysfunction results in derangement of hemostasis and thrombosis. Thromboelastography (TEG) has emerged as a tool to guide resuscitative efforts. However, its utilization and application in liver transplant (LT) surgery are not well determined. We aim to identify possible effects of TEG utilization on product use and blood loss in LT.

Methods: Adult patients (age >18 years of age) who received LT between 2014 and 2020 were retrospectively reviewed. Those patients who underwent living donor, simultaneous or multi-organ transplants, re-transplants, and pediatric transplants (recipient <18 years of age) within this timeframe were excluded. Possible impact of TEG implementation on blood product use and intraoperative blood loss was analyzed. A subgroup analysis was done based on INR at transplant. The median, 75th, and 90th percentile of INR at transplant were used as cut-off values and patients were classified into four categories: no coagulopathy, mild, moderate, and severe coagulopathy groups.

Results: A total of 451 patients met inclusion criteria and were separated into TEG (n=144) vs non-TEG (n=307) groups. Background characteristics between these two groups were comparable. Overall, median blood products used were similar between TEG and non-TEG groups: pRBC (4[IQR 2-6] U vs 3[1-7] U, p=0.194); FFP (6[3-10] U vs 6[2-11] U, p=0.697); Cryoprecipitate (1[0-2] U vs 1[0-3] U, p= 0.954); platelet (1[0-2] U vs 0[0-2] U, p= 0.065). In the subgroup analysis, there was a significant decrease in product use in the TEG group with moderate coagulopathy, compared to the non-TEG group: pRBC (4.5[2.0- 6.8] U vs 7.0[6.0-10.0] U, p= 0.002); FFP (6.0[4.0-8.0] U vs 9.0[8.0-16.0] U, p=0.005); Cryoprecipitate (1.0[1.0-2.0] U vs 2.0[1.0-4.0] U, p=0.005). Tranexamic acid (TXA) use was significantly higher in the TEG group with median values of 1000 [0-1500] mg vs 0 mg (p<0.001). There was no difference in median blood loss 2750 [1200-5250] ml vs 3500 [2125-7750] ml (p=0.09). In the no, mild, and severe coagulopathy groups, there was no difference in blood product use, blood loss, or TXA use between the TEG and non-TEG groups.

Conclusions: TEG guided hemostasis and resuscitation in LT resulted in a decrease in product usage, as well as more utilization of TXA, likely by recognition of hyper-fibrinolysis, in patients with moderate coagulopathy defined as INR between 2.2 and 2.8.

Abstract# 1291

Benign Pneumatosis Intestinalis with Pneumoperitoneum in the Immunocompromised Patient: Three Cases

A. Mohamed, K. Delvecchio, T. Kitajima, M. Rizzari, K. Collins, A. Yoshida, S. Nagai, J. Denny, M. Abouljoud, *Department of Transplant and Hepatobiliary Surgery, Henry Ford Hospital, Detroit, MI*

Purpose: Isolated pneumatosis intestinalis after solid organ transplantation, as well as its surgical management in appropriate clinical context, is a well described entity. The management of concurrent pneumoperitoneum, however, is not as well understood. Consequently, we present three interesting cases of pneumatosis intestinalis with pneumoperitoneum where conservative management was warranted.

Methods: We present three cases of solid organ transplant patients demonstrating both operative and nonoperative management of benign pneumatosis intestinalis with pneumoperitoneum.

Results: Case #1: A 61-year-old male underwent deceased-donor liver transplant. The patient was found to have incidental, asymptomatic pneumoperitoneum on routine postoperative surveillance imaging at nine months, with evidence of pneumatosis intestinalis. Consequently the patient was surgically explored, resulting in no discernable cause. **Case #2**: A 75-year-old male underwent deceased-donor kidney transplant. Three months postoperatively the patient presented to clinic with diarrhea. Subsequent diagnostic imaging displayed pneumoperitoneum with pneumatosis intestinalis. This patient was also surgically explored, resulting in no discernable cause. **Case #3:** A 60-year-old female underwent a living- donor liver transplant. Eight months postoperatively she presented with incidental pneumoperitoneum and pneumatosis intestinalis. Interval imaging showed worsening pneumoperitoneum in addition to development of intraabdominal fluid collections. With the absence of identifiable cause and inconsistent symptoms this patient was successfully managed conservatively with antibiotics, percutaneous drainage and bowel rest.

Conclusions: Given the high index of suspicion for a hollow viscus perforation and the mortality associated with sepsis in the immunosuppressed patient, surgeons feel obligated to explore these subsets of patients. However, as depicted in each of the three described cases, nonoperative management is often an acceptable alternative in appropriate clinical context.

Machine Learning, Artificial Intelligence and Social Media in Transplantation

Abstract# 1292

Kidney Transplantation Management and Decision Support System

A. Demirag[1], Y. Wu[2], J. Lamp[2], S. Holland[1], A. Routt[2], L. Feng[2], *[1]Transplantation, University of Virginia Medical Cener, Charlottesville, VA, [2]Computer Science Engineering Systems & Environment, University of Virginia, Charlottesville, VA*

Purpose: Coordinating the management of patients' health statuses, tracking and scheduling testing, is a complicated process and involves a team of clinicians including transplant coordinators, nephrologists, surgeons and social workers. Currently, transplant coordinators must manually communicate with the other clinicians, track patient tests and follow up with patients who miss required testing. Such a process leaves a lot of room for human error and increases the burden and burnout of coordinators. Moreover, patients are confused by this process and may not be engaged in their care, resulting in worse health outcomes. To end this, we propose the development of a kidney transplant management and decision support system, which will automate test reminders, assignments and tracking, succinctly summarize and store relevant patient health statuses using a visual dashboard, and use patient data and machine learning techniques to learn a patient risk score that characterizes their risk/survivability of a kidney transplant. Such a system will improve coordination between the actors in the transplant care team, reduce transplant coordinator burnout, facilitate clinician decision making for patient treatment and waitlist decisions, and engage patients in their health management in order to improve transplant outcomes.

Methods: The tracking management system organizes the transplant waitlist and patient statuses and facilitates test assignments by suggesting specific tests for patients based on their demographic information, in order to maximize efficiency and minimize the potential for human error. It also contains a patient portal allowing patients to view their health information and test results, as well as receive reminders about upcoming appointments

Results: The decision support portion of the system facilitates clinician decision making by providing a machine learned and summary dashboards with visualizations that intelligently aggregate patient statuses. It also contains reminders and to do lists for clinicians and coordinators, contacting patients who have missed multiple tests, in order to reduce some of the burden placed on transplant coordinators.

Conclusions: The system is a prototyped and will be deployed for use at the UVA kidney Transplant Clinic. Through the use of an intelligent and automated tracking management and a decision support this system will improve clinic efficiency and reduce the potential for error for both the clinical transplant teams and their patients.

Abstract# 1293

Transplant Data Platform - An Augmented Clinical Intelligence Framework

C. Focht, W. Tian, J. Zeng, N. Dzebisashvili, S. Ghosh, *CareDx, Brisbane, CA*

Purpose: UNOS, SRTR, USRDS registries are rich in patient baseline data. However, all suffer from data attrition as patients move further out post-transplant or between different health providers. These data gaps can adversely affect prognostication models of graft and patient survival and so are often augmented by other data sources. Comparative effectiveness research (CER) platforms support dataflow from multiple data centers, enabling integration from a variety of sources into a single system. However, CERs have not yet been developed for transplantation. We outline why this platform provides application for machine-learning (ML) methodology and show how a system can enrich the predictive power and accuracy of transplant data models.

Methods: Transplant data platform (TDP) utilizes cloud-computing protocols, accessing data stored in the cloud or in-house. Its triple-tier, Apache Spark-based *data lakehouse* architecture enables the storage of raw, cleaned and aggregated data. There is currently no standardization of patient data storage at different centers. Instead of enforcing a center-level data-standardization principle, TDP resolves the diversity of data-formats into a unified TIDY data matrix. This enables efficient cleaning and indexing of data in preparation for invocation by the integrated ML engine (TensorFlow). ML model-based insights are synthesized in FHIR format and future designs will support federation through a web-based portal.

Results: TDP provides an augmented intelligence framework the transplant community can utilize. The compiled data can be leveraged by clinicians to support the development of federated data stores. It supports creation of anonymized patient cohorts in a clinically definable manner, as well as through automated feature selection as part of an AI workflow. It supports genotype to phenotype relationship analyses to provide precision medicine insights. Future evolution will enable researchers to share evolving ML models through the web portal to augment clinicians' patient risk assessment.

Conclusions: TDP hosts anonymized data from registries, transplant centers and other clinical sources. Its end-to-end architecture allows data ingestion, harmonization, mapping, analysis and dissemination. Being able to support both unstructured and structured data makes it practical to work with hospital EMRs and patient records. This is important as the field considers ways to support patient linkages and longitudinal analyses when building outcome orientation models ensuring secure provenance with strong governance.

Abstract# 1294

Machine Learning Approaches for Post-transplant Kidney Outcome Prediction

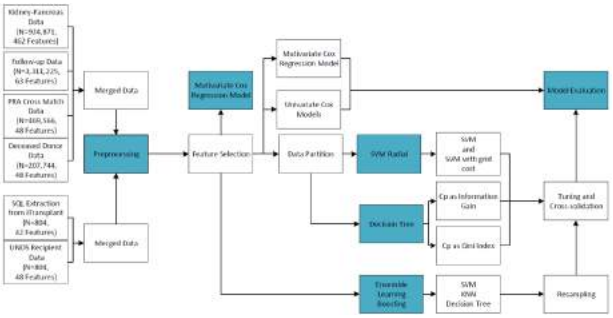
H. Ghali[1], D. Won[1], S. Yoon[1], A. Friedman[2], *[1]Systems Science and Industrial Engineering, SUNY Binghamton, Binghamton, NY, [2]LiveOnNY, New York, NY*

Purpose: Determine a robust prediction model for kidney graft survival based on analyzing a combination of decisive factors such as donor and recipient characteristics, biopsy, and perfusion machine parameters.

Methods: A collection of 632 locally transplanted kidneys that were recovered from deceased donors and pumped (1/1/17 - 12/31/18) were analyzed using data from an organ procurement organization (OPO) and UNOS data (see figure). A Consolidation of data preprocessing techniques, namely predictive mean matching and feature selection were employed. The data was subsequently utilized first in a survival analysis through univariate and multivariate Cox regression. A selection of machine learning algorithms was applied to the same dataset to develop a model for predicting kidney graft survival.

Results: The primary cox regression model resulted in a concordance index of 0.952, with DCD as the main predictor for graft survival (p= 0.004). Support vector machine (SVM: radial and grid of multiple cost parameters), decision tree (information gain and gini index), and ensemble learning (boosting) algorithms were applied. As a result, the ensemble learning outperformed all models by 93.7% accuracy (see table).

Conclusions: The model, that we developed, will provide an insight into making an informed decision about the transplant of kidneys considering their predicted final outcome. Furthermore, it could be used by OPOs to increase their organ utilization and possibly lowering the discard rate of kidneys.



Comparison of models performances					
Metrics	SVM Radial	SVM Grid	Decision Tree	Decision Tree Gini	Boosting
Accuracy	0.925	0.872	0.819	0.819	0.937
Sensitivity	0.882	0.794	0.588	0.588	0.895
Specificity	0.950	0.916	0.950	0.950	0.956

Abstract# 1295

"hlaR," a Simplified Interface for the HLA Matchmaker Tool

A. Johnson[1], J. Zhang[1], H. Gebel[2], C. Larsen[1], *[1]Surgery, Emory University, Atlanta, GA, [2]Pathology, Emory University, Atlanta, GA*

Purpose: Functional epitopes, or eplets, represent a set of amino acids within three angstroms of one another that may not be sequentially contiguous but are neighbors in three-dimensional space. The HLA Matchmaker tool, developed by Rene Duquesnoy, catalogues the eplets of each HLA allele and identifies mismatched eplets between donor:recipient pairs. The degree of eplet mismatching correlates with patient outcomes. Unfortunately, the scalability and magnitude of application has been restricted by the time and effort required at the user interface

Methods: We developed a software package using the programming language R, with capacity to build into a user-friendly web application, that dramatically reduces the effort of the end user. The tool is a compilation of several functions. HLA typing data on a population of one or many donors and recipients is read into R. The data is then converted into a consistent format using the function AlleleClean. Cleaned data are processed using the functions, CalEpletMHCI and CalEpletMHCII, which generate both a detailed output of the eplet mismatches between paired samples and a simplified output with the numerical count of mismatched eplets. Allele level mismatch can be analyzed with the function EvalAlleleMism. Finally, the AlleleTopN function generates a list of the most common alleles in the user's dataset. We demonstrate through applied vignettes the simplified workstream allowed by our R package, hlaR, accessible at https://github.com/LarsenLab/hlaR.

Results: User data input can be tailored to the intended application. The most common use of eplet data has been retrospective analysis of patient outcomes in the context of the mismatch load between recipient and donor (1 to 1). Analyzing a dataset of contrived donor recipient pairs with high-resolution HLA typed subjects, we observed equivalent results between hlaR and eplet mismatches calculated by HLAMatchmaker. Results were consistent excepting minor typographical errors traced to the excel workbook. To emulate the use of mismatch load in organ allocation, we provide an additional vignette, calculating mismatch between a single donor and a set of possible recipients or, similarly, between a set of donors and a single recipient (1 to many, many to 1).

Conclusions: Our new tool, hlaR, can provide simplified eplet data with a streamlined workflow for multiple applications. We plan to expand the functionality of this package to include imputation of low-resolution data by incorporating a query of the National Marrow Donor Program's HaploStats web application. With decreased effort from the end user, eplet matching and mismatch load data, which have been significantly associated with graft outcomes, can be further incorporated into both research and clinical use.

Abstract# 1296

Offer Acceptance Models for Various Endpoints: Initial Response, Final Response, and Conversion from Provisional Yes to Yes

C. Martinez, M. Stuart, A. Placona, *United Network for Organ Sharing, Richmond, VA*

Purpose: Offer acceptance models are routinely used for program evaluation and academic research, but the focus tends to be on modelling the final offer response. We explore different endpoints within the offer process, including modeling an initial response of provisional yes (PY) and conversion from PY to yes, to determine if the models associated with these endpoints vary with respect to prediction performance and significant covariates.

Methods: We collected donor, candidate, and match run data for kidney donors between 2015 and 2019 with at least one kidney transplanted. We replicated both the offer inclusion/exclusion criteria and the model architecture used by the SRTR for evaluating offer acceptance rates. We then modelled each of the following endpoints: if the initial response was a PY, if a PY was converted to a final yes, and if the final response was a yes. Each endpoint consisted of 4 logistic regression models (one each for all pediatric donors and adult donors stratified by high/middle/low KDRI) using the same covariates as the SRTR models. We compared covariates in each model as well as their predictive performance using a holdout set of the most recent 6 months of donors in the cohort.

Results: We noted distinct prediction performance across the models (Figure 1A). The final acceptance and PY conversion models had similar precision-recall (PR) curves, but the conversion model yielded higher precision across all recall thresholds. The initial response model had markedly better prediction performance than both the final acceptance and PY conversion models with an area under the PR curve of 0.67 vs 0.31 and 0.35.

Covariates also differed in significance and magnitude between the three models. A selection of covariates beta values are shown in Figure 1B. In particular, we observed that offer number (analogous to sequence number) was relatively less impactful for the PY conversion model, but time on dialysis and distance between donor and candidate hospitals were relatively more important.

Conclusions: We analyzed the same model architecture across 3 different offer acceptance endpoints. Although some models were similar, each had distinct predictive performances. These distinctions suggest that applications using offer acceptance models may benefit from choosing a model tailored to the application context. Future research in this domain would include evaluating different model architectures and fine-tuning model parameters for each offer acceptance endpoint.

Abstract# 1297

Quality Improvement Surveillance by Machine Learning

J. D. Perkins[1], E. Clemens[2], M. Granich[3], J. Yeung[3], J. Reyes[1], *[1]Surgery, University of Washington, Seattle, WA, [2]Pharmacy, University of Washington, Seattle, WA, [3]Center of Clinical Excellence, University of Washington, Seattle, WA*

Purpose: The purpose of this quality study was to compare our newly developed natural language processing (NLP) machine learning surveillance algorithm in detecting the rate of rejection episodes in our liver transplant recipients to our previous electronic medical record (EMR) structured data collection system.

Methods: In 292 consecutive liver transplant recipients from 2/9/2017 to 2/4/2020 with a follow-up to 6/1/2020, 27 (10.3%) recipient were confirmed to have a rejection episode (biopsy and treatment) within 3 months of transplantation by two transplant professionals. A phrase-based NLP surveillance algorithm evaluated the transplant notes of the healthcare providers for the first three months following transplantation to label recipients with a rejection episode. The recipients labeled with a rejection episode in our EMR as entered by transplant providers during the care of these recipients were recorded.

Results: The EMR recorded events labeled 19 (70.4%) rejection episodes correctly, missed 8(29.6%) rejection episodes, and mislabeled 12 rejection episodes that were not rejection episodes. The NLP surveillance algorithm labeled 21(77.8%) rejection episodes correctly, missed 6 (22.2%), and mislabeled no rejection episode that were not rejection episodes. The kappa coefficient agreement statistics to the confirmed list for the NLP algorithm of 0.86 (CI 0.75 to 0.97) was much better than the EMR recorded events of 0.61 (CI 0.46 to 0.77).

Conclusions: Transplant programs follow many quality measures to improve their care of their patients. Following these measures have required cost and time of chart abstractors or busy clinicians directly entering these events into structure fields in the EMR. We have shown that the evolving machine learning method of phrase-based NLP is better labeling transplant recipients as having rejection events compared to recorded events in our EMR. The improved accuracy of NLP for surveillance of quality measures makes this a valuable technique for quality improvement surveillance.

Abstract# 1298

Needs of People with Kidney Transplantation During the Covid 19 Pandemic and Its Confinement, and the Role of Communication Technologies Through the "Patient Experience"

I. Revuelta[1], E. Palou[2], R. Scandurra[3], F. Oppenheimer[1], F. Diekmann[1], J. Escarrabill[2], B. Bayés[1], *[1]Department of Nephrology and Kidney Transplant, Hospital Clinic, Barcelona, Spain, [2]Chronic care program and patient experience, Hospital Clinic, Barcelona, Spain, [3]Department of Statistics, Universidad Autónoma de Barcelona, Barcelona, Spain*

Purpose: During the COVID-19 pandemic, healthcare services have focused on the care of acute processes and there is a risk of not meeting the needs of complex chronic high-risk patients, such as kidney transplant patients(KT). Our goal is to understand the unmet needs/problems of KT during COVID-19 lock-down from the "patient experience" perspective, and to analyze the role of communication technologies.

Methods: Development of a survey through concepts grouped into categories (units of meaning) and synthesized into metacategories extracted after interviews with 3 stable and confined KT focus groups (videoconference; verbal informed consent). Verbatim transcription of the conversation and analysis with MAXQDA software(https://www.maxqda.com/). After validation, the surveys were compared with those of the group of CJ Atchison et al in the UK general population (authorization in order).

Results: Out of 1528 KTs, 947 answered (response rate:63%). 64.2% men, and 55% over 55years. Post-TR time:3m-5a. 115 concepts, 21 categories and 3 meta-categories were identified (in order of importance for patients: Role of technology (69%), Impact of lock-down (19%) and Contact with professionals(12%)). Our KTs have a serious concern about the disease (if infection, 38% believe that their life would be at risk; and 48% think that the infection would be serious), but not about their kidney disease (20.6%), 99.7% of KTs have taken measures of social distancing, and lock-down has not meant a change in their lifestyle (sleep, diet, exercise, and family or social relationships). On a scale of 1-6 (1 little-6 a lot), for the KTs the global impact has been 1.69, very different from that of the UK ($p<0.05$). Regarding healthcare needs, 27.7% reported having received information from the hospital, but not very useful; 42.3% have stopped doing some medical control, but only 1.92% have stopped the medication. During the pandemic, 55% contacted a specialist, by telemedicine in a 84.7% (preferring by video-call). KTs understand that technology does not replace all face-to-face technology and positively value group videoconferences (therapeutic education, dietary recommendations, physical activity).

Conclusions: KTs are people at risk, and they have serious concern about the disease, so they comply with lock-down, although this has not led to a significant change in their lifestyle. KTs value having easy access to professionals, information from the center, and consider technology a key role during lock-down. These learnings should profoundly change the way health professionals relate to patients, allowing an increase in the number of contacts and reducing face-to-face visits.

Pancreas

Pancreas and Islet: All Topics

Abstract# 1216

Donor-Derived Cell-Free DNA Can Differentiate Rejection versus Other Causes of Pancreas Transplant Dysfunction

N. Ali[1], J. Miles[2], Z. Stewart Lewis[1], *[1]Transplant Institute, NYU Langone Health, New York, NY, [2]CareDx, Brisbane, CA*

Purpose: Assessment and early detection of allograft injury in simultaneous pancreas and kidney (SPK) transplant recipients has clear benefits for optimizing treatment and intervention. Donor-derived cell-free DNA (dd-cfDNA) is an established biomarker for surveillance of kidney transplant recipients and an increasing body of evidence supports its utility in SPK transplantation.

Methods: SPK patients were monitored prospectively with dd-cfDNA (AlloSure, CareDx Brisbane), initiated at the discretion of the treating physician. dd-cfDNA was drawn concomitantly with standard of care laboratory testing including serum creatinine, amylase, lipase, DSA and BK PCR. Pancreatic graft dysfunction was defined by elevations in serum amylase and lipase or dysregulated glucose control.

Results: A total of 9 SPK patients were identified with a total of 49 AlloSure dd-cfDNA results. Median patient age was 48 years (range 26-56). There were 5 females (56%) recipients, 2 Caucasian (22%), 3 Black (33%) and 4 Hispanic (44%) recipients. 6 SPK patients had stable graft function and 3 SPK patients developed pancreatic graft dysfunction. The median AlloSure dd-cfDNA level in stable SPK patients was 0.18% (IQR 0.12-0.39%, Figure 1). One SPK recipient with stable pancreatic enzymes had an AlloSure dd-cfDNA level of 1.3% in the setting of sub-therapeutic tacrolimus levels, which normalized with titration of immunosuppression. Of the 3 SPK recipients with pancreatic graft dysfunction, 1 patient had an AlloSure dd-cfDNA level of 3.5% associated with clinical allograft rejection. AlloSure dd-cfDNA levels decreased to 0.14% within 1 month of empiric treatment. The remaining 2 SPK recipients with graft dysfunction had paired AlloSure dd-cfDNA levels of 0.42% and 0.52%. These patients were subsequently diagnosed with a bowel obstruction and partial splenic vein thrombosis as the cause for graft dysfunction.

Conclusions: In stable SPK recipients, AlloSure dd-cfDNA levels remain low during the post-transplant course. In this case series, AlloSure dd-cfDNA was able to differentiate allograft injury associated with rejection from alternative etiologies of graft dysfunction. Elevated dd-cfDNA levels associated with rejection and sub-therapeutic immunosuppression decreased following intervention. Further studies are required to further define reference values and response to intervention.

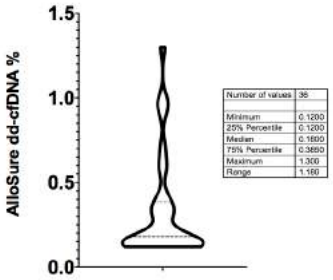

Figure 1: AlloSure dd-cfDNA distribution in stable SPK patients (36 draws from 6 unique patients).

Abstract# 1217

Induction in Pancreas Transplantation: T-Cell Depletion vs. Il-2 Receptor Blockade

F. Aziz, S. Parajuli, D. Kaufman, J. Odorico, D. Mandelbrot, *University of Wisconsin, Madison, WI*

Purpose: There are limited data comparing outcomes with different induction agents in pancreas transplantation. In this study, we compare T-cell depletion to IL-2 receptor (IL2R) blockade for patient and pancreas allograft survival, rejection, and infectious complications.

Methods: We analyzed the records of all patients who underwent simultaneous pancreas- kidney (SPK) or pancreas transplant alone (PTA) at our institution between 01/01/2011 and 12/31/2017. We found no statistically significant differences between anti-thymocyte globulin and alemtuzumab recipients in patient survival, graft survival, rejection or infection, so the two groups were combined for further analysis. In addition, there were no significant differences between SPK and PTA recipients in the impact of T-depletion versus IL2R blockade on outcomes, so the two groups were combined for further analysis.

Results: Of 317 pancreas transplant recipients, 191 received induction with a T-depleting agent (139 with anti-thymocyte globulin and 52 with alemtuzumab), and 126 received induction with an IL2R blocker (basiliximab). The mean follow-up post-transplant was 5.2 ± 2.4 years. There were a total of 12 (4%) patient deaths, 6 (3%) in the T-depletion group, and 6 (5%) in the IL2R blockade group. Similarly, there were a total of 33 (17%) death censored pancreas graft failures in T-cell depleting group and 22 (17.4%) with IL2R blockade (p=0.9). No difference was detected in patient (p=0.3) or pancreas allograft (p=0.8) survival between the two groups. Also, no statistically significant difference was found in pancreas allograft rejection between the two groups (48 vs. 43; p=0.2). Bacterial and CMV infections were significantly more common in the patients who received T-cell depleting agents for induction (p=0.001, p=0.01, respectively). On multivariate analysis, history of pancreas rejection (HR=3.47, p=0.0002; 95% CI 2.02 to 5.93) and history of previously failed pancreas allograft (HR=2.0, p=0.01; 95% CI 1.18 to 4.46) were associated with increased risk of pancreas allograft loss, but choice of induction was not (HR=0.76, p=0.31; 95% CI 0.45 to 1.28). Further, on multivariate analysis, HLA-mismatching (HR=1.17, p=0.08; 95% CI 0.98 to 1.39) and CMV infection after transplant (HR=2.3, p=0.0005; 95% CI 1.45 to 3.80) were associated with increased risk of pancreas allograft rejection, but choice of induction was not (HR=0.77, p=0.22; 95% CI 0.73 to 1.10). Similarly, further analyses showed CMV infection was associated with increased risk of patient death (HR=3.84, p=0.03; 95% CI 1.11 to 13.21) but choice of induction was not not (HR= 0.88, p=0.8; 95% CI 0.27 to 2.81).

Conclusions: We suggest that IL-2 receptor blockade may be a reasonable choice of induction for pancreas transplant recipients at low immunological risk.

Abstract# 1218

Endocrine Cell Identity and HOMA-B In Patients with Chronic Pancreatitis Undergoing Islet Auto-transplantation

C. A. Beamish[1], O. Gaber[2], O. M. Sabek[2], *[1]Surgery, Houston Mehodist Hospital, Houston, TX, [2]Surgery, Houston Mehodist, Houston, TX*

Purpose: Islet identity loss is an emergent factor in dysglycemia in diabetes, islet transplantation, and chronic pancreatitis (CP). Pancreatectomy and islet auto-transplantation (PIAT) for CP treatment is a useful model for assessing islet function in the absence of immune-suppression and to perform extensive pre-surgical metabolic testing not possible in cadaveric-sourced donor. We recently showed that in CP-PIAT patients, pre-surgical elevations in insulin resistance metrics proinsulin and HOMA-IR were associated with poorer post-surgical glycemic outcomes (insulin dependence) as well as histological islet identity loss. Here we sought to examine other measures of pre-surgical islet function and estimates of PIAT success using HOMA-β and insulin independence equations in a larger auto-transplant patient cohort.
Methods: Seven PIAT patients were assessed for β-cell function metrics, including pre- and 6-month-post-transplant HOMA-β by fasting insulin and glucose, comparison to the SUITO index using C-peptide, and proposed insulin independence by the BETA-2 score. Pancreas histology at PIAT was examined for changes in cellular maturity markers and compared with non-diabetic and T2DM donor controls.
Results: Pre-PIAT, low-HOMA-β was largely predictive of post-PIAT insulin dependence. Pre- and post-PIAT HOMA-β-CP values closely aligned with the SUITO equation, and there was a general correlation between BETA-2 score post-PIAT relative to the predicted index threshold for insulin independence. Histological data supported serological estimates of β-cell function, showing that poor HOMA-β pre-transplant corresponded with increased insulin-glucagon and insulin-vimentin colocalization, and reductions in Ins/Syp ratio, UCN3 presence, and overall islet area.
Conclusions: These data encourage further examination of islet identity peri-transplant and the association with pre-surgical serological β-cell function, as well as the use of PIAT for studying β-cell phenotype and its functional clinical implications.

Abstract# 1219

Outcomes of Covid 19 in Candidates Waitlisted for Kidney and Pancreas Transplantation

R. El-Rifai[1], S. Riad[1], R. Belina[2], A. Matas[2], *[1]Medicine, University of Minnesota, Minneapolis, MN, [2]Surgery, University of Minnesota, Minneapolis, MN*

Purpose: The COVID 19 pandemic has posed new challenges to transplant centers. The impact has been detrimental on wait-listed ESKD patients, reducing their access to life saving kidney transplant and prolonging time on the waiting list. Waitlist status is an independent predictor of hospitalization among COVID-19 infected kidney transplant candidates and is associated with increased mortality as high as 34% in one center. In this study, we aim to characterize the impact of COVID-19 on patients waitlisted for kidney and pancreas transplant at our center.
Methods: We performed a retrospective chart review of adult candidates waitlisted for kidney transplant at our center who tested positive for COVID-19. We reviewed baseline patient demographics and co-morbidities, severity of COVID-19 illness, hospitalization rate, and mortality.
Results: 38 patients waitlisted for kidney transplant, simultaneous kidney-pancreas, pancreas transplant alone tested positive for COVID-19 between March and November 2020. Of these, 22 (71%) were listed for 1st kidney transplant, 7 (13.4%) for SPK, 6 (15.8%) for 2nd kidney transplant, 3 (7.9%) for pancreas transplant alone. COVID-19 waitlisted candidates had median age-47 years (20-75), 20 (52.6 %) males. 52.6% white, 18.4% Hispanic, 15.7% Asian, and 13% Black. Significant racial disparities were noted especially among the Hispanic population who account for only 3.4% of our waitlist candidates but seem to have increased predilection for COVID 19 infection. The vast majority 30 (78.9%) of COVID 19 waitlist patients are hypertensive; and 17 (44.7%) diabetic. 25 (65.8%) of patients were treated as outpatient, 10 (26.3%) required hospitalization and 3 (7.9%) died. Critically, of the 38, only 3 (2 pancreas waitlist; 1 kidney) have recovered sufficiently to be reactivated on the waitlist. Mean time has been 16.7 weeks (SE=2.7 weeks) (range 13-22 weeks).
Conclusions: COVID19 infection has a significant impact on candidates waitlisted for kidney and pancreas transplantation. At our center, mortality has been 7.8%, hospitalization, 26.3%. But, to date, only 7.8% have been reactivated on the waitlist, predisposing them to increased morbidity and mortality.

Abstract# 1220

One-Year Monitoring of Changes to Kidney-Pancreas Waiting Time Criteria: An OPTN Analysis

R. C. Forbes[1], B. Plucinski[2], J. White[2], N. T. Kyaw[2], R. Kandaswamy[3], S. V. Niederhaus[4], *[1]Surgery, Vanderbilt University, Nashville, TN, [2]UNOS, Richmond, VA, [3]Surgery, University of Minnesota, Minneapolis, MN, [4]Surgery, University of Maryland, Baltimore, MD*

Purpose: In 2018, the OPTN board approved changes to kidney-pancreas (KP) waiting time criteria. KP candidates accrued waiting time if they were (1) on insulin and had a C-peptide <=2ng/mL or (2) on insulin and had a C-peptide >=2ng/mL and had a BMI <=30kg/m^2 which was the maximum allowable BMI. Since 7/11/2019 candidates must be on insulin, registered for a KP, and meeting kidney waiting time criteria.
Methods: Registrations added to the waitlist and transplants between 7/11/2018-7/10/2019 (pre-implementation) or 7/11/2019-7/10/2020 (post-implementation) were compared. Data originated from OPTN waitlist, Transplant Candidate Registration forms and Transplant Recipient Registration forms as of 10/16/2020.
Results: 1,389 registrations were added to KP and 42,229 to kidney alone (KI) waitlists (pre-implementation); 854 KP and 19,196 KI transplants performed. 1,401 registrations were added to KP and 19,493 KI waitlists (post-implementation); 814 KP and 19,493 KI transplants performed. The proportion of type 2 diabetes (T2DM) KP candidates and recipients increased from 23.29% to 27.45% and 21.41% to 27%, respectively (Table 1). Candidate mean BMI increased from 25.7 to 26.3. KP recipients with T2DM and C-peptide >2ng/mL had higher median BMIs than those with lower C-peptide. KP post-transplant outcomes stratified by ethnicity, BMI, and diabetes status remained similar. The proportion of KI candidates and recipients remained roughly unchanged. Pediatric KI organ offers increased (527 to 592 offers per 100 active patient-years) but transplants remained unchanged.
Conclusions: Changes in KP waiting time criteria did not adversely affect KI or pediatric KI candidates. Removing the BMI cutoff for obese patients with T2DM resulted in higher BMI KP transplants with equivalent post-transplant outcomes compared to lower BMI recipients. Although total KP transplants were slightly less in the post-implementation period, registrations were more and the transplant volumes were likely adversely affected by the COVID-19 pandemic.

Abstract# 1221

Update on Pancreas Retransplantation- A Registry Analysis

A. Gruessner, J. Renz, S. Saggi, R. Gruessner, *SUNY Downstate Medical Center, Brooklyn, NY*

Purpose: A successful pancreas transplant provides patients with brittle diabetes the opportunity of good long-term metabolic control. While initially more and more retransplants were performed, the number of pancreas retransplants decreased by 75% between 2004/05 and 2018/19. This may be due to the technically demanding procedure and the suboptimal outcome in certain subgroups. We analyzed outcome of pancreas retransplants over the past 15 years.

Methods: All 1368 pancreas retransplants performed between 1/1/2004 and 12/31/2019 were included. Comprehensive univariate and multivariable models were developed to describe outcome and potential risk factors for retransplant graft outcome. To describe the impact on long term graft function in the primary graft an artificial cut point of 5 years was chosen.

Results: Between 1/1/2004 and 12/31/2019 1025 pancreas retransplants were performed (66% rePAK, 15% rePTA and 19% reSPK). The decrease in numbers was mainly due to the smaller number of rePAK. Of the primary failed transplants, the majority (58%) were SPK. Over the years, the rate of patients who lost their primary graft for immunological reason increased from 52% to 58%. This was due to the increased better long term function after primary transplant. The median time of pancreas graft function in this primary pancreas grafts increased from 49 mos to 87mos. The longest failed primary pancreas functioned for over 25 years before being retransplanted. Pancreata that failed for early technical reasons were retransplanted early as well as pancreata that functioned > 5 years. Pancreata that failed early due to immunological reasons showed the longest time between failure and retransplant.

Conclusions: With careful patient and donor selection pancreas retransplants in all 3 recipient categories can be successful. Only primary pancreas transplants that failed due to early acute rejection carried a significantly higher (early) risk for retransplant failure. The use of depleting induction therapy and the standard maintenance protocol of tacrolimus and MMF further decreased the risk of retransplant failure loss.

Abstract# 1222

Development of De-novo Malignancies After Kidney and/or Pancreas Transplantation in Diabetic Patients

A. Gruessner, S. Saggi, J. Renz, R. Gruessner, *SUNY Downstate Medical Center, Brooklyn, NY*

Purpose: Transplantation of a kidney (KTA), pancreas (PTA), or a simultaneous pancreas-kidney (SPK) in a patient with end-stage organ failure is a lifesaving treatment. Patient and graft survival improved significantly over time due to more effective immunosuppressive agents; however, their long-term use increases the likelihood for developing posttransplant malignancies. This study analyzed the incidence of de-novo malignancies in diabetic patients after organ transplantation.

Methods: All primary technically successful primary pancreas and/or kidney transplants performed between 2005 and 2019 were included. Pancreas after kidney transplants were excluded: (1) the pancreas is a retransplant and (2) the time interval between the 2 transplants can be long. De-novo primary malignancies reported to UNOS/OPTN or reported as cause of graft loss or death were used. Patients with previous malignancies, lymphoproliferative disease, or donor-related malignancies were excluded. To provide comparable age distribution between KTA and SPK and PTA, all pancreas transplants were matched by age, gender, and transplant year with KTA in diabetic patients only. The Kaplan Meier Method was used to estimate the rate of malignancy over time. Descriptive statistics were performed and a multivariable risk model for the development of de-novo malignancies was developed.

Results: In 22,721 transplants (11,364 KTA, 1,013 PTA, 10,344 SPK) a total of 1,122 primary malignancies were diagnosed over time. Figure 1 shows the development in the 3 categories. At 5- (10-) years the cancer rate was 3.1% (8.3%) in KTA, 3.6% (10.4%) in SPK, and 5.3% (13.7%) in PTA (p<0.0001). Table 1 list the frequencies of the most frequently reported malignancies. Differences in the frequency between pancreas and kidney transplants were found for squamous/basal skin cancers (PTA, SPK > KTA) and cancers of the genitourinary system (KTA > SPK, PTA). Risk factor analysis identified older age and white race as the most influential risk factors followed by induction therapy with depleting antibodies.

Conclusions: In general, organ transplant recipients are at a greater risk for developing malignancies. Type and frequency of specific cancers vary between kidney and pancreas transplant recipients: Differences in type and frequency between pancreas and kidney transplants were found for squamous/basal skin cancers (PTA, SPK > KTA) and cancers of the genitourinary system (KTA > SPK, PTA). Long-term use of immunosuppression requires awareness for the development of malignancies and lifelong surveillance.

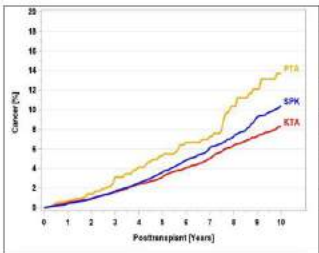

Figure 1: Time to development of a malignancy after transplantation in patients with diabetes mellitus

Malignancy	KTA	PTA	SPK
% Skin (Squamous/ Basal)	37	59	58
% Genitourinary	26	9	11
% Gastrointestinal	7	3	4
% Breast	6	4	5
% Lung	6	6	3
% Melanoma	2	4	5

Abstract# 1223

TPIAT Outcomes in Diabetic and Non-diabetic Patients

M. A. Kanak, J. B. Spriggs, P. Coughenour, J. Kalivarathan, P. Saravanan, M. Levy, *Virginia Commonwealth University, Richmond, VA*

Purpose: Total pancreatectomy with islet auto-transplant (TPIAT) has become a mainstay treatment for patients who suffer from refractory chronic pancreatitis. It has consistently been shown to reduce narcotic dependence and improve quality of life while simultaneously maintaining partial β cell activity, thus improving glycemic control post-operatively compared to pancreatectomy alone. A subset of patients with chronic pancreatitis already have underlying diabetes prior to surgery. Outcomes for this specific subset of patients has not been independently evaluated. In this study, we performed a comparative analysis of the TPIAT outcomes for diabetic and non-diabetic patient cohorts to determine if it produces the same long-term outcomes in both populations.

Methods: A total of 77 patients who had undergone TPIAT at Virginia Commonwealth University or Baylor University and were at least 1-year post-op were included in this study. 13 of the 77 patients were diabetic before undergoing TPIAT. Analysis included comparing demographics, pre-op Islet yield, and metabolic and pain outcomes both pre-op and at 1-year post-op. Additionally, the groups were adjusted for only those with islet dose (IE islet cells/kg patient weight) that were within +/- 1 SD of the average for diabetic patients. Once adjusted, metabolic and pain outcomes were again compared at both time points to determine if any of the differences seen were due to dose of islets available for transplant.

Results: Diabetic patients had higher rates of HTN at the time of transplant (61.5% compared to 25.0% of the non-diabetic group). There were no other differences in demographic variables. There was a significantly higher average islet cell yield in non-diabetic patients. This difference was eliminated when adjusted for islet dose. There was a significantly higher basal glucose and HgBA1c both pre-op and 1-year post-op for the diabetes cohort. These differences did not resolve with adjustment for islet dose. There was no difference in pre-op basal C-peptide, pain score or equivalent narcotic dosage at either the pre-op or 1-year post-op time points. There was no difference between groups in degree of change of basal c-peptide, HgBA1c, basal glucose, or pain score.

Conclusions: 1 year following TPIAT, both diabetic and non-diabetic patients experienced a worsening of their pre-op glycemic control and improvement in pain score and narcotic dependence. However, neither group experiences a disproportionate degree of those changes. Together, these results suggest that pre-transplant diabetes should not be considered as a contraindication for TPIAT.

Abstract# 1224

Comparative Outcomes of TPIAT in African American and Caucasian Patients with Chronic Pancreatitis

M. A. Kanak, J. B. Spriggs, P. Coughenour, J. Kalivarathan, P. Saravanan, M. F. Levy, *Virginia Commonwealth University, Richmond, VA*

Purpose: Total pancreatectomy with islet auto-transplantation (TPIAT) is becoming the standard of care for patients with chronic pancreatitis, as it provides pain relief and improved quality of life without the loss of glycemic control associated with total pancreatectomy alone. Despite these clear benefits and the high prevalence of chronic pancreatitis in the African American population, this procedure continues to be performed at significantly lower rates compared to the Caucasian population. In this study, we have performed a comparative analysis of the outcomes of the TPIAT procedure between African American and Caucasian patients. We hypothesize that no statistically significant differences in outcomes between these two groups indicates that the comparatively lower rate of TPIAT procedures seen in the African American population is rooted in a lack of access to high-quality healthcare and other social determinants, not worse outcomes.

Methods: A total of 84 Caucasian and 15 African American patients who had undergone TPIAT were included. Wilcoxon Rank tests were used to compare the HgbA1C, C-peptide, SUITO index, subjective pain score, and narcotic dose between these two groups at the pre-operative as well as 6-month and 12-month post-operative time periods.

Results: There were no significant differences in any of the surgical outcome measures between the two groups at either 6-month or 1-year post-operative. There were no significant differences in age at transplant or islet yield. Both Caucasian and African American patients experienced a decrease in pain score and narcotic dose at 6 months as well as an increase in basal glucose and HgBA1c.

Conclusions: These results indicate that African American patients have comparable outcomes to their Caucasian counterparts, suggesting that the disparity in the rate of TPIAT procedures performed in these two groups is contributable to social determinants such access to quality health care and the perception of physicians that African American patients can be expected to have worse outcomes comparatively. Based on these findings, we propose that physicians evaluating patients for TPIAT candidacy not use African American race as an indicator for expected surgical outcome.

Abstract# 1225

Symptoms on MTSOSD Questionnaire in Pancreas Transplantation Recipients

R. Kaur, S. R. Rizvi, B. H. Smith, C. Reid, S. K. McCrady-Spitzer, W. K. Kremers, P. G. Dean, A. Kukla, M. D. Stegall, Y. C. Kudva, *Mayo Clinic, Rochester, MN*

Purpose: We used the Modified transplant symptom Occurrence and symptom distress scale (MTSOSD) to study side-effects of immunosuppression after Pancreas transplantation (PT) for patients with Type 1 Diabetes (T1D).

Methods: After IRB approval, we prospectively studied 17 PT recipients (Six Aim 1, 11 Aim 2). Subjects were enrolled within a month of PT and completed 3 visits over a year in Aim 1and were enrolled at least 1 year post PT and completed 2 visits one year apart in Aim 2. All subjects completed MTSOSD at these time points. MTSOSD includes 60 symptoms and is completed for frequency (5 point Likert scale never to always occurring) and distress (5 point Likert scale not at all to very much distressing) of symptoms.

Results: Aim 1- 6 recipients (3 pancreas transplant alone {PTA}, 2 simultaneous pancreas kidney transplantation {SPK} and 1 Pancreas after kidney, all 6 insulin independent{II}) were 40.2 ± 21 years old, 5F, duration of T1D 24.4 ± 17.4 yrs with 32.8 ± 21.2 days interval from PT. Aim 2-11 (9 PTA, 2SPK, 10 II, 1 insulin treated) recipients were 55.6 ± 10.1 years old, 8F, duration of T1D 33.8 ± 12.2 years, 7.2 ± 5.2 yrs interval from PT. Aim 1- laboratory testing (labs) on all 3 visits (V1, V2 & V3) was satisfactory and similar except for improvement in HbA1c 6.1± 0.8% (V1) to 5.7 ± 0.9 % (V3). At least four side effects were reported by every subject with range 4-35 (Table). In course of 1 year, 5 of 6 experienced at least one grade 4 (very much distressing) symptom. 5 subjects included one on V1, 4 on V2 (all new) and 4 subjects on V3 (3 identical to V2 and one identical to V1). Two subjects out of 4 reporting grade 4 symptoms became insulin treated over the year. No significant difference was observed between visits regarding symptom frequency and distress. For Aim 2- labs were satisfactory and similar at both visits as well. During both V1 and 2, at least one side effect was reported by every subject with range 1-53. In course of 1 year, 5 subjects out of 11 experienced at least one grade 4 symptoms; Three on V1, 4 subjects on V2 (2 new and 2 same as V1). Subject who reported 24 grade 4 symptoms on V1 and 25 on V2 was insulin treated. Significant differences were seen between V1 and 2 for two symptoms "I have felt tired "(decreased, p 0.0239) and "I have been experiencing mood swings" (increased, p 0.0341). Table: MTSOSD symptoms frequency and symptoms distress

	Aim1 (n=6)	Aim2 (n=11)			
Variables	**Visit1**	**Visit2**	**Visit3**	**Visit1**	**Visit2**
Mean number of symptoms	21.3 ± 9.2	24 ± 12.7	20.8 ± 8.2	30.9 ± 14.3	29.5 ± 15.1
Range in number of symptoms	10-31	4-35	8-29	1-53	1-53
No. of subjects reporting Grade 4 symptoms (very much distressing)	1	4	4	3	4
Mean number of grade 4 symptoms	1 ± 0	1.3 ± 0.6	1.8 ± 0.5	12.5 ± 12.7	9.3 ± 10.9
Mean number of grade 1 to 3 symptoms reported	19.5 ± 6.9	18 ± 10.5	15.2 ± 6.6	25.2 ± 12.2	21.9 ± 12.6

Conclusions: PT recipients tolerate immunosuppression well but report some immunosuppressant related side effects in the first year and subsequently after PT.

Abstract# 1226

Diffuse Calcification Pattern in Chronic Pancreatitis Has Two Aspects in Total Pancreatectomy with Islet Autotransplantation: Bad Sign for Islet Graft Function and Good Sign for Pain Relief

Y. Liu, K. Kumano, J. Mattke, C. Darden, S. Vasu, M. Lawrence, G. Testa, A. Gupta, E. Beecherl, N. Onaca, B. Naziruddin, *Baylor University Medical Ctr, Dallas, TX*

Purpose: Chronic pancreatitis (CP) is characterized by progressive inflammation and fibrosis of the pancreas. The diagnosis of CP is based on pancreatic calcifications, ductal dilatation, and atrophy visualized by imaging with computed tomography (CT) and/or magnetic resonance imaging (MRI). Pancreatic calcification has been previously identified as a major risk factor for development of diabetes in CP patients and poor islet isolation, leading to poor insulin dependence at 1 year after total pancreatectomy with islet autotransplantation (TPIAT). However, the relationship of degree of calcification to TPIAT outcome is not analyzed so far. We retrospectively classified the calcification pattern based on localization, using preoperative CT imaging of CP patients undergoing TPIAT at our center.

Methods: Our database of 200 consecutive TPIAT procedures performed between 2006 and 2020 was retrospectively reviewed. Based on CT finding, two types of calcification pattern were defined; focal calcification (FC) and diffuse calcification (DC). Glucose level, HbA1c, C-peptide level, daily insulin requirement and insulin independence rate were measured at 3, 6 and 12 months after surgery. Narcotic dose and pain score was also calculated at same time points.

Results: 37 patients were identified as calcification cases. Among these cases, FC and DC cases were 16 and 21, respectively. Preoperative HbA1c levels of DC group was significantly higher than non-calcification (NC) group (6.5±1.1 vs 5.8±0.9%, $p<0.01$), and both basal and stimulated C-peptide of DC group were significantly low compared to NC group (basal; 1.2±0.8 vs 1.9±1.2ng/ml, $p<0.05$, stimulated; 3.2±1.9 vs 6.2±3.5ng/ml, $p<0.01$). Islet isolation of DC pancreas resulted in lowest total islet yield (IEQ) among the three groups ($p<0.0001$) and insulin independent rate at 12 month in DC group was 0%. ($p<0.05$ vs NC) (Figure 1A and B). However, narcotic free rate of DC group at 12 month was 91.7%, significantly higher than other groups ($p<0.05$ vs FC or NC).

Conclusions: Simple classification of pancreatic calcification pattern based on CT findings can predict preoperative endocrine function, islet isolation results and metabolic outcomes in CP patients undergoing TPIAT. Although DC is a sign of diabetes risk after TPIAT, DC group also showed advantage on pain relief. These findings suggest TPIAT can provide beneficial effect for patients suffering from severe chronic pancreatitis with calcification.

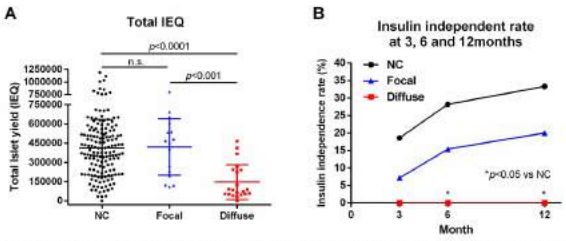

Figure 1A Scatter plot showing total islet yield (IEQ) of each patient in 3 groups. **1B** Insulin independent rate of 3 groups at 3, 6 and 12months after TPIAT.

Abstract# 1227

Dual-Agent Induction Therapy for Pancreas Transplantation: A Single-center Experience

E. C. Liu[1], J. H. Lee[1], R. Craig-Schapiro[2], M. Aull[2], S. Sultan[2], *[1]Pharmacy, NewYork-Presbyterian Weill Cornell Medical Center, New York, NY, [2]Kidney/Pancreas Transplant Surgery, NewYork-Presbyterian Weill Cornell Medical Center, New York, NY*

Purpose: The optimal induction strategy in pancreas transplantation has not been elucidated. Available evidence supports use of both basiliximab and lymphocyte depleting agents. Rabbit anti-thymocyte globulin (rATG) is associated with more infusion-related concerns such as cytokine-release syndrome, hypotension, and tachycardia, but is associated with lower rates of rejection. There is no available literature to date that describes the combined use of both agents. This study explores outcomes of traditional basiliximab induction compared to a single intraoperative dose of basiliximab to avoid adverse hemodynamic events followed by reduced dose rATG.

Methods: This is a single-center retrospective study of 24 adult simultaneous kidney-pancreas or pancreas alone transplants from January 2017 to December 2019. Historically, induction at our center was basiliximab 20mg on post-operative day 0 (POD0) and POD4. In 2018, the induction protocol was revised to single dose basiliximab POD0 followed by rATG for a total dose of 4.5mg/kg. Triple maintenance immunosuppression for all patients consisted of tacrolimus, mycophenolate mofetil (MMF), and prednisone.

Results: Seventeen patients received basiliximab alone, and 7 patients received the combination protocol of basiliximab + rATG. Baseline patient characteristics were similar between both groups (Figure 1). Mean tacrolimus trough levels were similar between groups and all patients received corticosteroids. MMF starting dose for all patients was 2g/day, with the average dose decreased to 1g/day by 12 months due to gastrointestinal side effects or bone marrow suppression. This maintenance immunosuppression was similar between groups. At 1 year, there was no difference in patient or pancreas graft survival (Figure 2). Biopsy proven acute kidney rejection (BPAR) incidence was 6% in basiliximab and 14% in the basiliximab + rATG induction group. Despite increased immunosuppression, postoperative complications and infections were not increased in the basiliximab + rATG group. Only patients who received basiliximab alone induction developed CMV viremia (n=3); however, there was more CMV seronegative mismatch within this group.

Conclusions: In this single-center study, overall outcomes of patients who underwent pancreas transplantation using two different induction regimens (basiliximab vs. basiliximab + rATG) are comparable with no increased infections in the dual induction group.

Figure 1. Baseline Characteristics

	Basiliximab (n=17)	Basiliximab + ATG (7)
Type of transplant, n (%)		
SPK	13 (76)	7 (100)

Abstract# 1228

Impact of Insulin Therapy in Pancreas Transplantation Donors on Graft Outcomes: An Analysis of the Optn/unos Database

E. Montagud-Marrahi[1], F. Ausania[2], Y. Fundora[2], A. Amor[3], E. Esmatjes[3], J. Ferrer[2], I. Revuelta[1], D. Cucchiari[1], J. Rovira[4], M. Musquera[5], C. Fondevila[2], F. Diekmann[1], P. Ventura-Aguiar[1], *[1]Nephrology and Kidney Transplantation Department, Hospital Clinic de Barcelona, Barcelona, Spain, [2]Hepatobiliopancreatic and Liver Transplant Department, Hospital Clinic de Barcelona, Barcelona, Spain, [3]Endocrinology Department, Hospital Clinic de Barcelona, Barcelona, Spain, [4]Laboratori Experimental de Nefrologia I Trasplantament (LENIT), CRB CELLEX, Fundació Clínic, IDIBAPS, Hospital Clinic de Barcelona, Barcelona, Spain, [5]Urology Department, Hospital Clinic de Barcelona, Barcelona, Spain*

Purpose: Hyperglycemia requiring insulin treatment is frequent in critically ill patients and potential pancreas donors. Information on the impact of donor insulin use on pancreas outcomes is scarce. Thus, we explored the influence of donor insulin use on recipient and pancreas graft survival.

Methods: Retrospective study with 12841 pancreas recipients (either simultaneous pancreas-kidney, pancreas after kidney or pancreas alone) from the OPTN/UNOS registry performed between 2000 and 2017. Multivisceral recipients other than simultaneous pancreas-kidney, those transplants from a donor < 30 kg and recipients with diabetes other than type 1 or 2 were excluded. Insulin donor requirements were defined as the need for any dose of insulin within 24 hours prior to donation.

Results: A total of 7765 (60%) patients received a pancreas from a donor with insulin requirements. Pancreas graft survival (death-censored) at 1 year was similar between those who received an insulin-requiring donor and the remaining (89% vs 89%, $P > 0.05$), as well as at 5 and 10 years (78% and 69% vs 79% and 70%, respectively, $P = 0.35$)(Figure). Donor insulin therapy was not associated neither with an increased risk of recipient death (HR 0.93 [95% CI 0.80-1.07], P = 0.29) nor pancreas graft failure (HR 1.08 [95% CI 0.99-1.17], P = 0.09).

Conclusions: Insulin requirements in a potential pancreas donor is not associated, *per se*, with an impaired pancreas graft and patient survival. Thus, donors who require insulin therapy may be suitable for pancreas transplantation.

Abstract# 1229

Human Leukocyte Antigen Mismatches Between Donor-Recipient or Donor-Donor are Not Associated with Adverse Pancreas Outcomes in Pancreas After Kidney Transplant Recipients

S. Parajuli, D. Kaufman, B. Welch, H. Sollinger, D. Mandelbrot, J. Odorico, *University of Wisconsin, MADISON, WI*

Purpose: A greater degree of HLA mismatch has been previously associated with inferior graft survival in kidney and pancreas transplantation. Pancreas after kidney (PAK) recipients are in a unique situation. On one hand, these recipients have been immunosuppressed for months to years before their pancreas transplant, and on the other hand, they will be exposed to new HLAs from the pancreas donor. How pancreas outcomes among HLA mismatched PAK recipients might differ depending on whether there is a mismatch between pancreas donor and recipient (PD-R) or pancreas donor and kidney donor (PD-KD) are unknown.
Methods: All primary PAK transplants between 1997 and 2019 at our center were included in this study. Patients were divided into two groups based on the degree of HLA mismatching: low (L-MM) as 0-4 and high (H-MM) as 5-6. We analyzed all (N=73) PAK for PD-R mismatch during the study period, and the subset of PAKs in whom both kidney and pancreas were transplanted at our center for PD-KD mismatch (N=37). Pancreas graft survival and rejection rates were determined over the entire time period.
Results: The mean interval between kidney and pancreas transplants in the PD-R cohort was 45.2 months. Comparing L-MM (n=39) and H-MM (n=34), we observed no difference in the overall rate of graft loss. 64% of grafts failed (46% death censored, DCGF) in the L-MM group and 62% (26% DCGF) in H-MM (p=0.84). There was also no difference in the overall rate of rejection throughout the whole period [L-MM (33%) vs H-MM (41%)], nor the severity of rejection. We observed a statistically significantly (p<0.01) earlier time to acute pancreas rejection in the H-MM group (6.8 +/- 8.7 mo) vs the L-MM cohort (29.0 +/- 36.2 mo). When stratified according to the type of pancreas transplant induction agent, we observed the overall acute rejection rates to be similar: L-MM(depletional) 33%(6/18), L-MM (IL-2RA) 33% (7/21), H-MM (depletional) 41% (7/17), and H-MM (IL-2RA) 41% (7/17). For the analyses PD-KD subset, 37 recipients had both organs transplanted at our center: 15 were in L-MM and 22 in H-MM. The mean interval between two transplants were 31.2 months. We observed no statistically significant difference in the incidence of pancreas graft loss: 53% grafts failed (27% DCGF) in L-MM and 68 % (41% DCGF) in the H-MM group (p=0.37). We observed no statistically significant difference in the incidence or severity of rejection. When stratified according to the type of pancreas transplant induction agent, the overall acute rejection rates were similar.
Conclusions: We did not find a negative impact of HLA mismatch among PAK recipients on either pancreas graft survival or rejection rates.

Abstract# 1230

Early Increases in Post-Transplant Pancreatic Enzymes are Not Associated with Inferior Patient or Graft Outcomes Among Pancreas Transplant Recipients

S. Parajuli, G. E. Leverson, B. Welch, H. Sollinger, D. Kaufman, D. Mandelbrot, J. Odorico, *University of Wisconsin, Madison, WI*

Purpose: An increase in the serum concentration of pancreatic enzymes (amylase and lipase) is commonly related to an acute inflammatory process in the pancreas graft among pancreas transplant recipients (PTRs). The association between immediate post-operative increases in pancreatic enzymes and long-term post-transplant graft and patient outcomes is unknown.
Methods: We analyzed all PTRs transplanted at our hospital between 06/2009 and 09/2018. Due to changes in the normal laboratory values for amylase (A) and lipase (L) during the study period, enzyme levels were presented as a ratio of absolute numbers to the upper limit of normal value, with value > 1 considered as abnormal. We specifically evaluated patient and graft survival based on the amylase or lipase ratios on day 1 (A1, L1) and maximum ratios within 5 days of transplant (Amax, Lmax). We also evaluated outcomes after excluding grafts that failed within 90 days of transplant.
Results: There were a total of 443 PTRs during the study period, 287 were simultaneous pancreas and kidney (SPK) recipients, and 156 solitary pancreas recipients (SP). There was a total of 102 pancreas graft failures,yet an early rise in enzymes was not associated with pancreas graft failure: A1 (HR: 1.02, 95% CI: 0.97-1.06, p=0.45); Amax (HR: 1.02, 95% CI: 0.97-1.06, p=0.46); L1 (HR: 1.0, 95% CI: 0.96-1.04, p=0.99); Lmax (HR: 1.01, 95% CI: 0.97-1.04,p=0.72). There were 46 deaths during the study period. High immediate post-transplant pancreatic enzyme levels were not associated with patient mortality: A1 (HR: 1.05, 95% CI: 0.99-1.10, p=0.08); Amax (HR: 1.05, 95% CI: 0.99-1.10, p=0.09); L1 (HR: 1.02, 95% CI: 0.98-1.06, p=0.24); Lmax (HR: 1.03, 95% CI: 0.99-1.06, p=0.07). Similarly, there were 117 PTRs with biopsy-proven pancreas rejection, and similarly, no association with early post-transplant enzyme increases was observed. Similar findings were seen when considering SPK only or SP only in separate analyses, or after excluding grafts that failed within 90 days of transplant thereby focusing on non-technical failures, or including outcomes only 1-year post transplant. Finally, we failed to reveal an association between immediate post-transplant enzyme increases with long-term functional graft outcomes as measured by C-peptide or HbA1c.
Conclusions: In this large series of PTRs, immediate post-transplant increases in pancreatic enzymes, reflecting early graft pancreatitis, possibly due to ischemia reperfusion injury, was not associated with patient survival, pancreas graft survival, rejection, or long term endocrine graft function. More studies in this field are needed.

Abstract# 1231

Early Increases in Post-Transplant Pancreatic Enzymes Are Associated with Surgical Complications Among Pancreas Transplant Recipients

S. Parajuli, G. Leverson, B. Welch, H. Sollinger, D. Kaufman, D. Mandelbrot, J. Odorico, *University of Wisconsin, Madison, WI*

Purpose: An increase in the serum concentration of pancreatic enzymes (amylase and lipase) is commonly related to an acute inflammatory process in the pancreas graft among pancreas transplant recipients (PTRs). The association between immediate post-operative increases in pancreatic enzymes and post-transplant complications is unknown.
Methods: We analyzed all PTRs transplanted at our hospital between 06/2009 and 09/2018. Due to changes in laboratory assays during the study period, enzyme levels were presented as a ratio of absolute numbers to the upper limit of normal value, with value > 1 considered as abnormal. We specifically evaluated bleeding, fluid collections (including enteric leak, enzyme leak, pancreatic ascites etc), and thrombosis complications based on the amylase or lipase ratios on day 1 (A1, L1) and maximum ratios within 5 days of transplant (Amax, Lmax). PTRs with index complications that occurred before the date of enzyme determination were excluded. We focused on technical complications which occurred within 90 days of transplant.
Results: There were a total of 443 PTRs during the study period, 287 were simultaneous pancreas and kidney (SPK) recipients, and 156 solitary pancreas recipients (SP). There were a total of 78 PTRs with complications of interest. Higher A1 (HR: 1.05, 95% CI: 1.02-1.09, p=0.004); Amax (HR: 1.06, 95% CI: 1.02-1.09, p

<0.001); L1 (HR: 1.03, 95% CI: 1.01-1.05, p=0.009); Lmax (HR: 1.03, 95% CI: 1.01-1.05,p=0.002), were associated with an increase in early complications. Similar findings were seen when considering SPK only or SP only in separate analyses. When considering specific complications such as fluid collections, bleeding or thrombosis, we observed a significant association between higher immediate post-transplant enzyme increases and fluid collection complications, whereas we did not observe a similar association with bleeding, or partial or complete thrombosis complications.
Conclusions: In this large series of PTRs, early increases in pancreatic enzymes was associated with early post-transplant surgical complications, especially post-operative fluid collections. This finding suggests cases of early perioperative enzyme increases merit consideration for early imaging investigation to mitigate detrimental outcomes.

Abstract# 1232

Corticosteroid Reintroduction in Urban Simultaneous Kidney-pancreas Transplant Recipients Following an Early Corticosteroid Withdrawal Protocol

D. Pierce, P. West-Thielke, M. Campara, I. Tang, M. Spaggiari, I. Tzvetanov, E. Benedetti, A. Lichvar, *University of Illinois at Chicago, Chicago, IL*

Purpose: Approximately 30% of patients who undergo simultaneous kidney-pancreas (SKP) transplant are maintained on dual therapy with tacrolimus and mycophenolate. Long-term implications of steroid reintroduction in an early corticosteroid withdrawal (ECSWD) population remain unknown. The purpose of this study is to describe the incidence of corticosteroid reintroduction across an urban ECSWD SKP transplant population.
Methods: Adult SKP transplant recipients between 1/1/2003 - 12/31/2018 at University of Illinois Hospital & Health Sciences System were assessed. Patients were excluded if they were maintained on steroids post-SKP, had early technical failure, and had graft thrombosis. The primary outcome was to describe the incidence and indication of steroid reintroduction. Acute rejection (defined as biopsy-proven acute rejection [BPAR] or empiric treatment) between the groups. Metabolic parameters were also assessed. Death-censored graft failure (DCGF) and patient survival were compared with survival analyses.
Results: A total of 86 patients were included. Baseline demographics are detailed in Table 1. Steroids were reintroduced in 33.7% of patients at a median of 467 days (IQR 190 - 919 days) post-SKP. Steroid were restarted for infection/malignancy (65.5%), rejection (27.6%), or immunosuppression intolerance (6.9%) (Table 2). No differences were observed in metabolic parameters (Table 3). The incidence of acute rejection was significantly higher in patients with steroid reintroduction (Table 3). Patients who maintained ECSWD demonstrated less DCGF with no difference in patient survival (Table 4).
Conclusions: Steroid reintroduction most commonly occurred for infection/malignancy immunosuppression modulation. Patients that necessitated steroid resumption experienced shorter DCGS compared to those patients who were maintained on the ECSWD protocol with no adverse effects on metabolic parameters.

Table 1. Demographics Information

Variable	Whole cohort (n=86)	ECSWD (n=57)	Steroids Reintroduced (n=29)	p-value

Abstract# 1233

SPK Transplantation in HIV-positive Recipients

H. Resweber, k. nguyen, H. Curtis, J. Panichella, A. DI Carlo, S. Karhadkar, *Temple University School of Medicine, Philadelphia, PA*

Purpose: With the advent of anti-retroviral therapy in the treatment of HIV, mortality in HIV-infected individuals has become less due to complications from viral infection and more due to chronic issues such as organ failure and dysfunction. Organ transplantation has thus become a more popular therapeutic method to treat issues commonly seen in HIV+ patients. Although transplantations involving organs like livers and kidneys into HIV-infected individuals have become increasingly common over the past decade, pancreas transplantation into HIV+ recipients is rarely performed. This is despite the fact that type II diabetes and insulin resistance remain a large problem for this population.
Methods: Using the UNOS database and SPSS, we examined the 31 incidences of pancreas transplantation that have occurred in HIV+ patients in the US. All of these transplantations were simultaneous pancreas-kidney (SPK) procedures, with the first occurring in 2009 and the most recently recorded occurring in 2017.
Results: When compared to SPK transplantations in HIV-uninfected individuals over a similar timeframe, pancreas graft function was similar (80.6% for HIV+ vs 85.3% for HIV-) and pancreas graft survival was higher (583 days for HIV+ vs 533 days for HIV-) in the HIV+ recipients.
Conclusions: These results suggest that, similar to outcomes seen in kidney and liver transplantations for their respective diagnoses, pancreas transplants might provide a viable therapeutic option for the treatment of diabetes and insulin resistance in HIV+ individuals. More research has to be done on the rates of patient survival of HIV+ SPK recipients, which we found to be much lower than their HIV-uninfected counterparts (647 days for HIV+ vs 1059 days for HIV-), but the successes in both graft function and graft survival provide an optimistic outlook on the role of SPK transplantation in the treatment of common complications seen in HIV+ individuals.

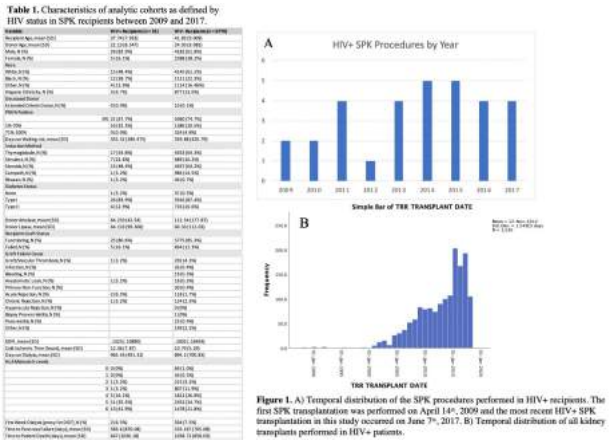

Figure 1. A) Temporal distribution of the SPK procedures performed in HIV+ recipients. The first SPK transplantation was performed on April 14th, 2009 and the most recent HIV+ SPK transplantation in this study occurred on June 7th, 2017. B) Temporal distribution of all kidney transplants performed in HIV+ patients.

Abstract# 1234

Donor Derived Cell-Free DNA (dd-cfDNA) in Pancreas Transplant Recipients

S. Riad[1], H. Sarumi[2], R. Kandaswamy[3], *[1]Medicine, University of Minnesota, Minneapolis, MN, [2]Surgery, University of Minnesota Physicians, Minneapolis, MN, [3]Surgery, University of Minnesota, Minneapolis, MN*

Purpose: Data on the role of DD-cfDNA after pancreas transplantation is lacking. Herein we report on our center experience with DD-cfDNA in 10 unique SPK recipients and eight pancreas alone transplants.

Methods: We retrospectively reviewed all DD-cfDNA (Prospera™) testing in simultaneous-pancreas-kidney (SPK) and solitary pancreas transplant recipients performed in 10 unique SPK recipients (11 tests) and 8 unique solitary-pancreas recipients (10 tests) between January and June of 2020 at our institution. All patients with suspected rejection underwent DD-cfDNA testing. Patients with a positive test underwent a biopsy, except for one subject with known chronic rejection. Among those with a negative test, a biopsy was performed selectively in those with a high degree of suspicion for rejection.

Results: 10 SPK recipients were tested 11 times. 8 tests were negative, and 3 tests were positive. Of the recipients with negative tests, 2 underwent kidney and 2 others underwent pancreas biopsies for results confirmation. Of the kidney biopsies, 1 biopsy showed pyelonephritis and CNI changes, and the other biopsy was negative. Of the pancreas biopsies, 1 was indeterminate for rejection, and the other was negative for cellular rejection but showed some c4d positivity without circulating DSA. Of the positive tests, 2 tests were performed on the same recipient before the biopsy, which showed moderate cellular rejection. The other positive test was confirmed with a kidney biopsy showing acute cellular rejection grade Banff IA (Table 1).8 unique solitary pancreas were tested 10 times. 2 tests were positive. Of the recipients with a positive test, 1 was not biopsied due to known chronic rejection and evidence of several DSAs at high MFI levels. The other recipient had a biopsy-proven mixed rejection that was successfully treated with subsequently negative tests (Table 2). Of the recipients with a negative test, 2 subjects had confirmatory biopsies: 1 was pancreas biopsy, and the other was kidney biopsy. Both biopsies were negative for acute rejection. All subjects with a negative test result who did not undergo a biopsy had no evidence of clinical rejection on follow up.

Conclusions: In this early report on DD-cfDNA in pancreas recipients, DD-cfDNA correlated with negative and positive biopsy results in all subjects with confirmatory biopsy. The accuracy of the test was not altered by the presence of more than one organ. While these early results are encouraging, further prospective studies are needed to confirm our results.

Abstract# 1235

Induction Immunosuppression Efficacy in Pancreas and Kidney Transplantation in the SARS-CoV-2 Era

H. Sarumi, K. Vassar, S. Jackson, T. Pruett, R. Kandaswamy, *University of Minnesota, Minneapolis, MN*

Purpose: Lymphocyte depleting induction is associated with increased risk of infection. Our institution adopted a stratified induction protocol with the intent to decrease risk for recipients exposed to SARS-CoV-2. Baseline protocol was 6-7.5 mg/kg thymoglobulin with a 3 dose steroid taper. This was modified to a protocol based on immunologic risk. Low risk group included KTA (PRA <20%) was basiliximab 40 mg and 4 week steroid taper; intermediate group was KTA (PRA 20-80%) or SPK (PRA <80%) and consisted of thymo 2 mg/kg and basiliximab 40 mg with 4 week steroid taper; high risk group included any recipient with PRA >80%, PTA, positive DSA and induction was unchanged from the pre-SARS-CoV-2 protocol. All recipients received tacrolimus/MMF maintenance. The primary objective was to evaluate the effect of adjusting induction immunosuppression on acute cellular rejection (AR) and infection rates.

Methods: Outcomes of all adult transplants performed between March 24-October 18, 2020 were reviewed. Time to first infection and AR was analyzed using Kaplan-Meier curves. Patients were censored at the earliest of death, graft failure or 10/22/20.

Results: 81 patients were assessed: 61 KTA, 2 PTA, 18 SPK. Demographics: 69.1% Caucasian, 59.3% male, 84.0% primary transplant and 76.5% deceased donor. 2 grafts were lost: one due to thrombosis on POD 0 and the other due to primary non function. There were 2 deaths: one due to CVA/MDR TB and another due to NSTEMI. Populations of the 3 risk groups: low (16), intermediate (33) and high (32). In the low risk group there were 2 (12.5%) AR within 6 weeks of transplant. One of these patients developed AMR, BK and CMV.

The intermediate group included 6 (18.2%) recipients who developed AR. 2 of these recipients developed 2 AR episodes, the first episodes were within 4 weeks of transplant. The first had Banff 1A in addition to AMR followed by borderline AR a month after initial biopsy. The second had 2 episodes of borderline AR and that graft ultimately failed due to primary non function. Of note the pathology of the other 4 recipients was consistent with borderline AR.
There were 2 (6.3%) AR in the high risk group. The first was 1A within 6 weeks of transplant, this patient also developed EBV and CMV. The second was IIA within 3 weeks of transplant.
There was no significant difference in AR rates among these groups (log rank p-value 0.396).
No significant difference in overall infection rate (p-value 0.482), bacterial (p-value 0.906), fungal (p-value 0.553) or viral (p-value 0.494). An asymptomatic recipient tested positive for SARS-CoV-2 in the high risk group 2 months following KTA.
Conclusions: Optimal induction regimens for pancreas and kidney transplant in the SARS-CoV-2 era remain unclear. Although rejection rates in the abbreviated induction groups were slightly higher, most were borderline. Short-term infection rate did not seem to be impacted. Tailored induction regimens stratified by risk may be safe and effective during this pandemic era and beyond.

Abstract# 1236

COVID-19 Presentation and Severity Within One Year of Pancreas and Kidney Transplantation

H. Sarumi, J. Fisher, B. Johnson, T. Pruett, *University of Minnesota, Minneapolis, MN*

Purpose: The current pandemic has created uncertainty of induction regimen impact upon severity of COVID-19 disease. Our experience with COVID-19 infection was reviewed to stratify outcomes of infection occurring before or after one year from transplant.
Methods: All COVID-19 PCR positive pancreas and/or kidney transplant recipients were reviewed for demographics and outcomes.
Results: 65 recipients were identified: 9 <1 year and 56 >1year post-transplant. There were clinically relevant differences between groups. In the <1 year group 100% received thymoglobulin induction and 2 (22.2%) received steroid rejection treatment 2 and 10 months prior to COVID-19 diagnosis. Of recipients > 1 year from transplant there were no rejection treatments within the year prior. Maintenance immunosuppression was CNI/MMF in 66.1%. Infection <1 year post-transplant resulted in no mortality nor worse outcomes. In fact 3 recipients were asymptomatic (tested for upcoming procedure, known exposure or admission). Mild-moderate symptoms (cough, fever) were the cause for testing in 4, but symptoms were of insufficient severity to warrant admission. All non-hospitalized patients recovered without sequala. 2 patients were hospitalized for COVID-19 disease. One recipient had a prior lung transplant and developed fever and hypoxia. Treatment with MMF reduction, dexamethasone and remdesivir permitted avoidance of intubation and discharge within a week. The other hospitalized patient was asymptomatic at positive test, but developed diarrhea and weight loss 2 weeks after initial diagnosis. Other causes of diarrhea were ruled out and it was concluded that symptoms were COVID-19 related, as PCR remained positive. There were no respiratory symptoms. Infections diagnosed >1 year after transplantation were diagnosed because of symptoms, had a higher rate of hospitalization and death. Due to small sample size, statistical significance of increased severity was not feasible.
Conclusions: With a limited experience, COVID-19 infection within the first year after transplantation does not appear to have a greater mortality or need for hospitalization after lymphocyte depletion induction contrasted to recipients acquiring COVID-19 greater than a year after transplantation.

Figure 1: Demographics

	<1 Year	>1 Year
Average Age	57.2 (46-68)	51.5 (16-82)
Sex: Male	44.4%	55.0%

Abstract# 1237

COVID-19 Transmission within One Year from Pancreas and Kidney Recipients

H. Sarumi, J. Fisher, B. Johnson, T. Pruett, *University of Minnesota, Minneapolis, MN*

Purpose: The current pandemic has created uncertainty surrounding the transmission of COVID-19. It was recently published that in the general population, household contacts have a 53% rate of secondary infection from index patient (Grijalva et al. (2020). MMWR, 69(44), 1631.). Our experience was reviewed in an effort to understand transmission in the immunosuppressed population. The primary objective was to evaluate the effect of recent induction upon COVID-19 transmission to contacts.
Methods: A retrospective review of adult recipients with COVID-19 detected by PCR within one year of pancreas and kidney transplant was conducted. These patients were interviewed regarding the timeline of their symptoms and the symptoms and testing of household and close contacts.
Results: 9 patients were identified: 8 Kidney and 1 Kidney/panc. All were primary transplants, except one with a prior lung transplant 2 years earlier, 33.3% were Caucasian, 33.3% Black, 22.2% Asian, 11.1% Hispanic, 55.6% female, 66.7% deceased donor, BMI ranged from 23.1-31.9 and age ranged from 46-68. 66.6% were tested due to symptoms. There were no recipient deaths, graft loss, rejection or decreased graft function resulting from COVID-19. Induction immunosuppression consisted of thymoglobulin (5.2-6.4mg/kg) and 3 dose methylprednisolone. The kidney after lung received 2 mg/kg thymoglobulin. All recipients had tacrolimus/MMF maintenance. Of these recipients, 5 had a history of infection post-transplant, 2 others had concurrent infections with COVID-19. 22.2% had a history of steroid treated rejection prior to diagnosis. The time to diagnosis of COVID-19 ranged from 2 to 12 months post-transplant. All 9 recipients were the index case in their household as far as could be determined, as there were no household contacts reporting symptoms or positive tests prior to the recipient. The recipients had a total of 20 household contacts, 3 (15%) tested positive, 8 (40%) asymptomatic and tested negative, 1 (5%) developed cough but tested negative and 8 (40%) asymptomatic and not tested. In addition to household contacts there were 7 people identified as close contacts; 1 close contact was the likely source of COVID-19 to a recipient, 2 that did contract COVID-19 after recipient exposure and 4 tested negative. One recipient appeared to transmit COVID-19 to 3 contacts, 1 of whom he lived with and 2 other close contacts. There was no indication that the asymptomatic recipients transmitted COVID-19 to any contacts.
Conclusions: We found no evidence that pancreas and kidney recipients contracting COVID-19 within the first year after transplant had a higher rate of household/close contact transmission than the general population. The recipients were encouraged to wear masks and minimize contact with others. This study suggests that in a very limited sample size, the risk to family members of COVID-19 PCR positive recipients does not appear greater than the general population. Precautionary distancing and barrier measures should be used.

Abstract# 1238

Systemic Venous versus Portal Venous Drainage in Simultaneous Pancreas-kidney Transplantation: A Matched-pair Analysis

B. Sharda, *Wake Forest Baptist Medical Center, Winston Salem, NC*

Purpose: Portal venous drainage of pancreatic transplant appears more physiologic compared to systemic venous drainage. However, present data does not support the superiority of one technique over the other. The study purpose was to evaluate outcomes in vascularized pancreas transplantation (PTx) with enteric exocrine drainage based on technique of venous delivery.
Methods: We retrospectively analyzed 231 simultaneous pancreas-kidney transplants (SPKTs) performed at our center between 7/2003 - 7/2019 and identified 27 that

were performed with systemic venous (iliac vein) and enteric exocrine (systemic-enteric [S-E]) drainage. These 27 patients were compared to 27 case controls with portal venous (superior mesenteric vein) and enteric exocrine (portal-enteric [P-E]) drainage matched for recipient age, gender, race, and date of transplant. All patients received similar immunosuppressive regimens and underwent standardized management protocols. Intention to treat was with P-E drainage.

Results: The 2 groups were well-matched for numerous donor, preservation, recipient, and immunological characteristics. Indications for S-E drainage were central obesity/thickened mesentery (10), unfavorable vascular anatomy (11), or surgeon preference (6). The S-E drainage group was characterized by slightly more patients ≥ 80 kg (44% S-E versus 26% P-E), with C-peptide positive diabetes (30% S-E versus 18% P-E), and with diabetes onset at >20 years of age (41% S-E versus 26% P-E, all p=NS), suggesting a Type 2 diabetes phenotype. Although the incidence of early pancreas thrombosis (3.7% S-E versus 0% P-E), early relaparotomy (30% S-E versus 22% P-E), and mean initial length of hospital stay (11 days S-E versus 8 days P-E) were numerically higher in S-E versus P-E SPKTs, none of these differences were significant. With a mean follow-up of 5 years in both groups, respective one and 3-year patient survival (100% and 96% S-E vs 100% and 100% P-E), kidney graft survival (100% and 96% S-E vs 100% and 89% P-E), and pancreas graft survival (96% and 96% S-E vs 100% and 100% P-E) rates were comparable.

Conclusions: The method of venous delivery of insulin following PTx does not appear to influence medium-term outcomes in SPKT with enteric exocrine drainage.

Abstract# 1239

Achilles Heel No Longer: Marked Decline in Early Relaparotomy and Allograft Pancreatectomy Rates Following Simultaneous Kidney-Pancreas Transplantation in the Contemporary Era

B. Sharda[1], K. Gurung[2], R. Stratta[2], A. Farney[2], G. Orlando[2], C. Jay[2], A. Reeves-Daniel[3], A. Mena-Gutierrez[3], N. Sakhovskaya[3], W. Doares[4], S. Kaczmorski[4], M. Magid[4], J. Rogers[2], *[1]Wake Forest Baptist Medical Center, Winston Salem, NC, [2]Department of Surgery, Wake Forest Baptist Medical Center, Winston-Salem, NC, [3]Internal Medicine, Wake Forest Baptist Medical Center, Winston-Salem, NC, [4]Department of Pharmacy, Wake Forest Baptist Medical Center, Winston-Salem, NC*

Purpose: Technical complications requiring early relaparotomy (relap) and allograft pancreatectomy (AP) have long been the Achilles heel of simultaneous kidney-pancreas transplantation (SKPT).

Methods: Single center retrospective review of all SKPTs from 11/1/01 - 8/12/20 managed with T-cell depleting antibody, tacrolimus, MMF, steroids, and enteric exocrine drainage. Anticoagulation other than ASA 81 mg was not routinely used. Early relap was defined as occurring within 3 months of SKPT. Patients (pts) were stratified into 2 sequential eras: Era 1 (E1): 11/1/01 - 5/30/13; Era 2 (E2) 6/1/13 - 8/12/20.

Results: During the period of study, 255 SKPTs were performed (E1, n=165; E2, n=90) with an overall mean follow-up of 8.1±5 years. Recipient age and donor and recipient ethnicity, gender, and BMI were comparable between eras. E1 pts received organs from older donors (E1 27 vs. E2 23 years, P<0.001) with longer pancreas graft cold ischemic times (CIT) (E1 16 vs. E2 13 hours, P=0.04). E2 pts received more imported organs (E1 16% vs. E2 27%, P=0.04). E1 pts had a higher early relap rate (E1 43% vs. E2 14%, P<0.001) and were more likely to require AP (E1 10.3% vs E2 2.2%, P=0.019). E2 pts underwent systemic venous drainage more frequently (E1 8% vs. E2 29%, P<0.001). The most common indications for early relap in E1 were pancreas thrombosis (12%), abscess/infection (12%), bleeding (4%), and leak (4%) whereas in E2 were for abscess/infection (3%), small bowel obstruction (3%), and thrombosis (2%), P=0.001. Pancreas venous drainage technique did not affect either early relap or AP rates. Actuarial death-censored pancreas graft survival rates are shown in Table 1. Mean transplant volume was 14/year for E1 and 13/year for E2; mean transplant volume in the past 3 years of E2 was 18/year.

Conclusions: Maximizing donor quality (younger donors) and minimizing CIT are paramount for reducing complications requiring either early relap or AP and for optimizing long-term pancreas graft survival following SKPT. Considering that the pancreas is the only organ for which supply exceeds demand, this can be achieved without compromising transplant volume by judicious use of imported organs.

Table 1. Death-Censored PG Survival

Abstract# 1240

Outcomes of Simultaneous Kidney-Pancreas Transplantation in Patients with Type-I and Type-II Diabetes Mellitus

H. Shokouh-Amiri[1], M. S. Naseer[1], A. Palermini[1], D. Aultman[1], R. McMillan[1], S. Tandukar[2], N. Singh[2], G. Zibari[1], *[1]Advanced Surgery, John C. McDonald Regional Transplant Center - Willis Knighton Health System, Shreveport, LA, [2]Transplant Nephrology, John C. McDonald Regional Transplant Center - Willis Knighton Health System, Shreveport, LA*

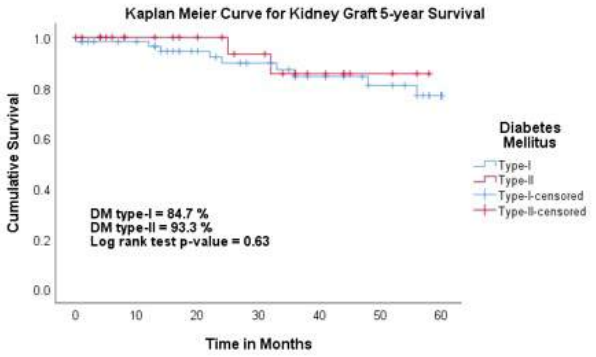
Purpose: UNOS approved simultaneous kidney-pancreas transplantation (SKPT) for type-II diabetes mellitus (DM) in Oct 2014. There is limited data comparing outcomes of SKPT in type-I versus type-II DM. The aim of this study was to measure the change in volume of SKPT since UNOS approved it for type-II DM patients and compare death-censored 5-year kidney and pancreas graft and patient survival between type-I and type-II DM patients undergoing SKPT.

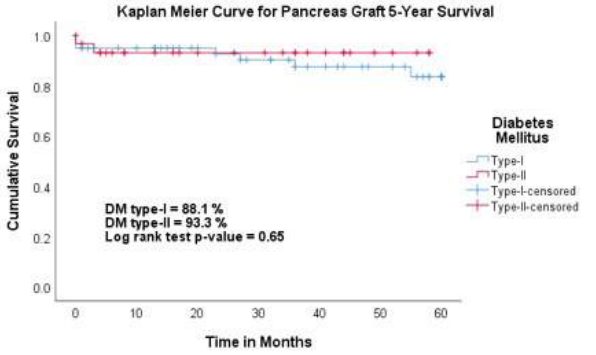
Methods: We conducted a single-center retrospective chart-review study on SKPT patients from Jan 2010 to Nov 2020 and collected data on patient demographics, BMI, c-peptide, HbA1c, and eGFR. Student's t-test for continuous variables, Chi-square test for categorical variables, and Log rank test for survival analysis were done using SPSS.

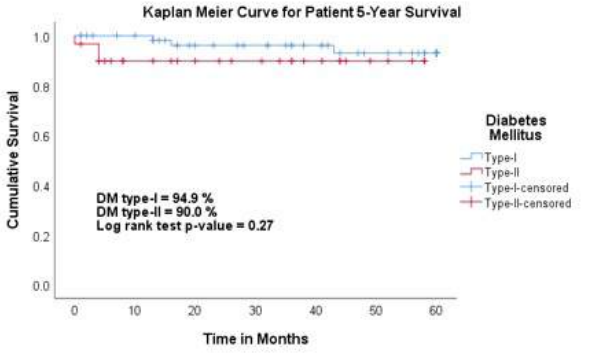
Results: Among 89 SKPT, 18 (all type-I DM) and 71 (41 type-I and 30 type-II DM) were done pre- and post-approval of SPKT for type-II DM respectively. This translated to an increase in SKPT from 3.6/year to 11.8/year (228% increase). There were no statistically significant differences in c-peptide and HbA1c levels pre- and 1-year post-SKPT. Patients with type-II DM were of older age and had higher BMI and eGFR 1-year post-SKPT. There were no statistically significant differences in death-censored kidney and pancreas graft and patient survival at 5-year post-SKPT.

Patient Demographics, Lab Parameters, and Survival Analysis

	DM type-I (n=59)	DM type-II (n=30)	P-Value
Age (Y), mean ± SD	40.2 ± 9.5	47.4 ± 8.8	<0.01
Male, % (n)	62.1 (36)	61.3 (19)	0.94
BMI (kg/m^2) Pre-SKPT, mean ± SD	25.9 ± 4.2	27.0 ± 2.8	0.15
BMI (kg/m^2) 1-Year Post-SKPT, mean ± SD	26.7 ± 4.6	32.0 ± 3.7	<0.01
eGFR (ml/min/1.73m^2) Pre-SKPT, mean ± SD	13.0 ± 8.0	13.6 ± 9.3	0.83
eGFR (ml/min/1.73m^2) 1-Year Post-SKPT, mean ± SD	62.0 ± 18.6	76.7 ± 22.6	0.04
Death-Censored 5-Year Kidney Graft/Pancreas Graft/Patient Survival, %	84.7/88.1/94.9	93.3/93.3/90.0	0.63/0.65/0.27







Conclusions: Approval of SKPT for type-II DM by UNOS led to an increase in SKPT with no differences in graft or patient survival between patients with type-I and type-II DM.

Abstract# 1241

Enteric Conversion After Bladder-drained Kidney-pancreas Transplantation

S. Sivan, M. Ortigosa-Goggins, M. Patel, M. Morsi, L. Chen, J. Figueiro, G. Ciancio, G. Burke, *Miami Transplant Institute, University of Miami Miller School of Medicine, Jackson Memorial Hospital, Miami, FL*

Purpose: In simultaneous kidney-pancreas transplantation (SPK), bladder (BD) and enteric (ED) are both options for pancreaticoduodenal exocrine drainage. While BD provides good early and long term SPK survival, it is associated with metabolic, urological and pancreatic complications leading to need for enteric conversion (EC). We report our single center experience in SPK recipients who underwent EC after initial BD.

Methods: Between 1990 and 2019, we performed 541 SPK, of which 474 were BD and 67 were ED. We retrospectively studied patients(pts) who underwent EC. Indications for EC, time from SPK to EC, resolution of symptoms, complications and pancreas graft survival were analyzed.

Results: 56/474 pts underwent EC (11.8%). The mean time to EC was 4.5 years (yrs) (median 2.58 yrs) with intervals <1 yr = 19(33.9%), 1-5 yrs =20(35.7%), 5-10yrs=7(12.5%), 10-20yrs =10 (17.8%) . The main indication for EC was dehydration followed by recurrent urinary tract infections (UTI). 3 pts had EC for pelvic congestion syndrome, presenting as labial/scrotal edema and pelvic pain. 4/11 (36.4%) pts who had EC due to UTI had persistent UTI, 7/11 (63.6%) had resolution of UTI; the rest of the pts had complete resolution of the primary indication. 6 (10.7%) pts had surgical complications post EC and 4/6 required re-exploration with ileoduodenostomy (bailout) operation for duodenal leak. Graft rejection was observed in 3 pts (5.3%) after EC and all were done 6-12 months post-transplant, time from EC to rejection was 3weeks-39months. The mean follow-up after EC was 5.7 yrs (median 4.25 yrs). Overall pancreas graft loss (GL) occurred in 7 pts (12.5%) after EC, including 2 pancreatectomies: 1 for duodenal fistula and 1 for gastrointestinal bleed. The mean interval between EC and GL was 4.1 yrs.

Indications	Total:56 N (%)	Time to EC from Transplant Mean (yrs)	Pancreas GL N(%) 7/56(12.5%)
Urological			
Pelvic Congestion syndrome	3 (5.3%)	15.1	0
Recurrent UTI	11 (19.6%)	4.3	0
Hematuria	6 (10.7%)	8.56	1/6 (16.6%)
Pancreatitis	9 (16%)	4.29	1/9 (11%)
Metabolic			
Dehydration	14 (25%)	2	4/14 (28.5%)
Acidosis	7 (12.5%)	2.6	0
Surgical			
Leak	3 (5.3%)	0.33	1/3 (33.3%)
Other	3 (5.3%)	17.3	0

Conclusions: In this single center review of SPK pts with initial BD, the rate of EC was low at 11.8%. Persistent UTI post EC may be due to diabetes-related bladder dysfunction and in isolation should not be an indication for EC. BD may still be considered as primary drainage in SPK if indicated with the caveat of possible reoperation for EC.

Abstract# 1242

Distal Allograft Pancreatectomy for Graft Salvage After Pancreas Transplantation

D. Soma, T. Nikumbh, A. J. Lutz, J. A. Powelson, J. A. Fridell, *Transplant Division, Department of Surgery, Indiana University School of Medicine, Indianapolis, IN*

Purpose: Early pancreas allograft failure most commonly results from vascular thrombosis. Immediate surgical intervention may permit pancreas allograft salvage, typically requiring thrombectomy. In cases of partial allograft necrosis secondary to splenic arterial thrombosis, distal allograft pancreatectomy may allow salvage of at least half of the pancreas allograft with retention of function.

Methods: The medical records for all adult patients who underwent deceased-donor pancreas transplantation at Indiana University Health University Hospital between January 2003 to October 2020 were retrospectively reviewed. Data came from the transplant recipient registry at our center and from individual electronic medical records. Simultaneous pancreas and kidney transplantation (SPK), pancreas after kidney transplantation (PAK), and pancreas transplantation alone (PTA) recipients were included.

Results: There were 710 pancreas transplants performed at Indiana University Health University Hospital between January 2003 and October 2020. During this period, four cases required distal allograft pancreatectomy for splenic artery thrombosis with necrosis of the distal pancreas. All four were SPK recipients. Their cases including post-transplant courses, are described in detail and summarized in Table 1. Three of the four maintained long-term allograft function with euglycemia independent of insulin at six months to six years of follow-up, and all patients continue to maintain normal renal allograft function.

Conclusions: Early diagnosis and early intervention are essential in order to salvage the pancreas allograft in the case of thrombosis. Distal allograft pancreatectomy can be performed safely and result in excellent long-term outcomes in select patients.

	Age at Tx	Indication for DAP	Timing of DAP	CEUS	Change in BS	Post DAP pancreatic leak	Length of stay (day)	Functional pancreas graft	Pancreas graft survival

Abstract# 1243

Psychosocial Outcomes 1-year Post Total Pancreatectomy and Autologous Islet Cell Transplant

J. Steel[1], A. Amin[1], M. Wijkstrom[1], A. Zureikat[1], E. Tillman[1], R. Jones[1], D. Yadav[1], A. Slivka[1], A. Phillips[1], M. Bellin[2], A. Carroll[3], A. Humar[1], *[1]University of Pittsburgh, Pittsburgh, PA, [2]University of Minnesota, Minneapolis, MN, [3]University of Pittsburgh Medical Center, Pittsburgh, PA*

Purpose: A paucity of research regarding the psychosocial outcomes after-total pancreatectomy and autologous islet cell transplantation exists. The aim of the study was to examine the psychosocial outcomes of patients who have undergone total pancreatectomy and autologous islet cell transplantation at 1-year post-surgery.

Methods: Adults (>18 years), adolescents (13-18 years), and children (5-12 years) and the children's parents were administered a battery of questionnaires at the time of evaluation and 1-year post-surgery. The battery of questionnaires included the BPI, CES-D, STAI, FACT-Fatigue, PSQI, FACES, RCBC, and SF-36. Repeated measures analyses of covariance was performed to assess changes in these symptoms relative to surgery.

Results: A total of 13 adult and 15 children/adolescents with chronic pancreatitis were included in the study. Of the adults, the majority were female (53.8%), Caucasian (100%) with a mean age of 35.2 years (SD=9.8). The mean age of the child/adolescent patients was 12.3 years (SD=2.6) and the majority were female (53.3%) and Caucasian (100%). A total of 69.2% of the adults and 80% of the children and adolescents were insulin dependent at 1-year post surgery. No significant differences were observed by etiology with the exception of fatigue (Wilks' Lambda=4.86, p=0.037) and SF-36 general health (Wilks' Lambda=9.27, p=0.011) with those having cryptogenic or substance use related etiologies having greater fatigue and poorer general health when compared to those with cystic fibrosis at 1-year post-surgery. Patients who underwent robotic-assisted surgery reported better general health than patients who underwent open surgery (Wilks' Lambda=6.0, p=0.040) at 1-year. After adjusting for age, improvements on the SF-36 social functioning (Wilks' Lambda=6.8, p=0.032); pain (Wilks' Lambda=24.9, p=0.001), and general health were observed (Wilks' Lambda=5.4, p=0.045) 1-year post-surgery. For the children and adolescents, reductions in pain (Wilks' Lambda=6.8, p=0.04), pain interference (Wilks' Lambda=14.3, p=0.04), and fatigue were observed (Wilks' Lambda=7.2, p=0.032) at 1-year post surgery.

Conclusions: While few transplant centers offer this treatment, the reduction in pain and improvement in quality of life suggests this may be a viable treatment option for those with chronic pancreatitis. Future cost-effectiveness research is needed to understand changes in health care utilization and costs after surgery.

Abstract# 1244

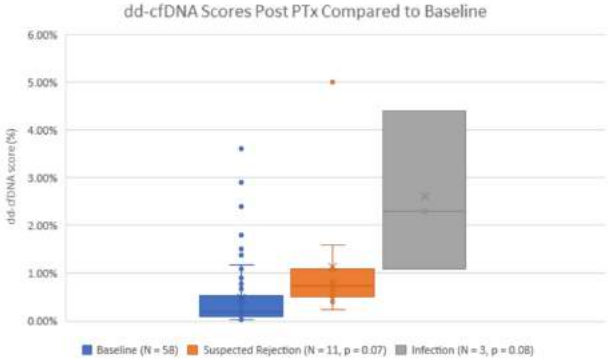
Baseline Levels of Dd-cf Dna After Pancreas Transplantation: Using Dd-cfdna as an Indicator for Pancreas Rejection and Biopsy Avoidance

A. Yoo, I. Qian, A. Riedel, C. Cazac, A. Bartosic, J. S. Bromberg, J. Scalea, *Department of Surgery, Division of Transplant, University of Maryland School of Medicine, Baltimore, MD*

Purpose: Donor-derived cell-free DNA (dd-cfDNA) testing, which has been previously validated for monitoring kidney transplant (KTx) rejection, may provide an alternative to pancreas biopsy that prevents morbidity and graft loss; in turn, we sought to determine for the first time baseline dd-cfDNA levels in pancreas transplant (PTx) recipients.

Methods: Blood samples up to 19 months post-PTx were collected from 28 participants.

Results: 25 patients received SPK, 3 received PTA, from whom 72 dd-cfDNA samples were collected of which 58 were used for baseline calculations. Three patients were excluded for infection and 11 for rejection. No patients died. Median dd-cfDNA scores peaked at 0.53% within one-month post-transplantation (range 0.20%-2.90%; mean 1.00±0.9%), then decreased to 0.20% (range 0.03%-3.60%; mean 0.45±0.8%). Median dd-cfDNA was 0.20% in patients without infection (range 0.03%-3.60%; mean 0.49±0.7%), and 2.3% with infection (range 1.10%-4.40%; mean 2.60±1%). Five patients underwent pancreas biopsy for cause (elevated lipase). Of these, three showed acute T cell mediated rejection (rejection rate 12%). The median dd-cfDNA score was higher with rejection (0.73%).



Conclusions: While median and mean levels of normal dd-cfDNA in KTx recipients are currently defined as <1.0%, baseline dd-cfDNA levels among PTx recipients show a median level of <1.0%, but a higher mean, particularly within one-month post-transplantation (1.00±0.9%). Elevation in dd-cfDNA may also correlate with pancreas rejection. Confirmation of these correlations and definition of normal cutoffs will require accruing more patients to our study.

Abstract# LB 90

Donor Derived Cell Free DNA Identifies Rejection in Simultaneous Pancreas Kidney Transplant Recipients

M. Williams[1], S. Ghosh[2], L. L. Jenkins[2], M. Hertl[1], S. Saltzberg[3], V. Peev[3], E. Chan[1], E. Hollinger[1], E. Schadde[1], O. Olaitan[1], *[1]Department of Surgery, Rush University Medical Center, Chicago, IL, [2]CareDx, Inc., Brisbane, CA, [3]Department of Internal Medicine, Rush University Medical Center, Chicago, IL*

Purpose: Increased level of donor-derived cell-free DNA (dd-cfDNA) has proven to be a sensitive marker for allograft rejection after solid organ transplant, particularly heart and kidney; the aim of this study was to determine the role of dd-cfDNA in diagnosing rejection after simultaneous pancreas-kidney (SPK) transplant.

Methods: We performed a single-center prospective cohort study of all SPK recipients starting in November 2019. Dd-cfDNA was measured using AlloSure (CareDx, Inc. Brisbane CA). Rejection events were diagnosed either clinically or with biopsy, and are specified in the results. Median values are provided with the interquartile range (IQR) for larger samples or the range when $n \leq 10$. Delta values were calculated using the dd-cfDNA value at the time of the rejection event and the lowest value prior to the event. Correlation between dd-cfDNA and lipase was determined by Pearson's correlation coefficient.

Results: 43 patients were included for analysis. Median number of dd-cfDNA visits per patient was 10, with 366 visits in total. In patients without rejection, median dd-cfDNA across all visits was 0.2% (n=290, IQR 0.15% - 0.39%). Among patients who were treated for rejection (n=8), median dd-cfDNA at the time of event was 3.5% (range 1.2% - 7.4%), and median delta dd-cfDNA was 506% (range 45% - 3764%). Of the 8 rejection events, 5 were diagnosed clinically and 3 were confirmed with biopsies, which demonstrated antibody mediated rejection (AMR) in kidney, AMR in kidney and pancreas, and mixed AMR/cellular rejection in pancreas. Their dd-cfDNA values were 1.6%, 3.2%, and 3.7%, respectively. 10 additional biopsies were performed which did not demonstrate rejection. At the time of negative biopsy, median dd-cfNDA was 0.37% (range 0.12% - 0.65%). Across all patients, there was a weak correlation between lipase and dd-cfDNA ($r=0.25$, $p<0.0001$). Notably, one patient with biopsy-confirmed pancreas rejection demonstrated lipase = 22 and dd-cfDNA = 3.2%. Conversely, another patient with lipase = 1100 and dd-cfDNA = 0.55% was biopsied and found to have pancreatitis.

Conclusions: Dd-cfDNA demonstrates promise in differentiating allograft rejection from non-rejection events in SPK recipients. Prospective surveillance of dd-cfDNA should be considered in this population, and could provide data for further investigation.

Purpose: To report on the Spanish Pancreas Transplantation experience in controlled donation after circulatory death (cDCD) by analyzing the normothermic regional perfusion (NRP) and super-rapid recovery

Methods: Data from January 2015 to December 2020 were analyzed regarding pancreas transplantations using cDCD donors

Results: Some 471 pancreas transplants were performed, 20 being from cDCD donors.NRP was used in 18 pancreases.The median functional WIT was 10 (7-15.5) min. NRP was run for 113.5 (91.5-134.5) minutes. Pancreas cold ischemia was 412.5 (330-636.7) minutes. **S**urgical complications were present in 70% of cases.Two patients of the NRP group presented with primary pancreas graft non-function. After a median follow-up of 13.6 (5.6-36.4) months, the 1 and 5-year overall pancreas survival rate was 85% for the whole series, 83.3% for NRP group and 100% for SSR group.Overall 1 and 5-year patient survival was 94.7%, with no group differences

Conclusions: To date, this is the largest series describing the use of postmortem NRP in cDCD pancreas transplantation, providing competitive results in terms of graft/patient survival

Abstract# 816

Characterization of SGLT2 Inhibitor Use After Abdominal Transplant

F. Hailemariam[1], S. Yeager[2], J. Schulte[3], P. Singh[1], A. Yadav[1], *[1]Transplant Nephrology, Thomas Jefferson University Hospital, Philadelphia, PA, [2]Abdominal Transplant Pharmacist, Thomas Jefferson University Hospital, Philadelphia, PA, [3]Abdominal Transplant, Clinical Pharmacist, Thomas Jefferson University Hospital, Philadelphia, PA*

Purpose: Post solid organ transplantation, diabetic kidney disease (DKD) can progress due to recurrent pre-transplantation diabetes or the development of post-transplantation diabetes mellitus (PTDM). This portends a higher risk of cardiovascular (CV) morbidity and mortality. Sodium-glucose cotransporter 2 inhibitors (SGLT2i) have been shown to slow DKD progression and decrease CV morbidity and mortality. Studies regarding the use of SGLT2i in abdominal transplant recipients (ATRs) are limited. This is a study to characterize the use of SGLT2i in ATRs.

Methods: This is a single-center, retrospective analysis of ATRs initiated on SGLT2i. Chart review was performed to study demographics as well as assess for acute kidney injury (AKI), urinary tract infection (UTI), CV events, change in weight, hemoglobin A1c (HbA1c), and baseline kidney function.

Results: SGLT2i were used in 20 ATRs, including 11 liver-, 8 kidney-, and 1 kidney after liver recipients. Recipients were white (55%) and male (65%), with an average age of 62 ± 7 years. Most patients had pre-transplant diabetes and 4 patients had PTDM (20%). Most patients were started on SGTL2i post-transplant at a median time of 48 months (IQR 30 - 82). Three patients were on SGLT2i pre-transplant. The most common agent was empagliflozin (55%). Most patients were initiated on SGLT2i by their endocrinologist (80%) or primary care physician. All patients were on additional therapy for blood glucose control, with a majority on insulin (89%). Most patients were maintained on a calcineurin inhibitor-based regimen (90%). After a median time from initiation to 378 months (IQR 168 - 588), average HbA1c and weight were lower and no differences were observed in kidney function (Table 2). AKI episode occurred in four patients, of which three were on diuretics. Uncomplicated UTI with Aerococcus occurred in one patient, with no episodes of fungal UTI. No episodes of amputation, CV event, or death were observed in this cohort

Conclusions: Our retrospective analysis shows SGLT2i can be effectively and safely used in ATRs to derive the kidney and cardiac benefits. Larger clinical trials with long term follow up are warranted

Abstract# 817

Systematic Evaluation of Immunosuppressant Drug Tolerability in Lung Transplant Recipients with Short Telomere Syndrome

R. Patolia[1], R. Guzy[2], L. Potter[1], *[1]Department of Pharmacy, University of Chicago Medicine, Chicago, IL, [2]Department of Medicine, Division of Pulmonology, University of Chicago Medicine, Chicago, IL*

Purpose: Lung transplant recipients with short telomere syndrome are at high risk of hematologic complications. Consequently, patients with short telomere syndrome may require more frequent dose adjustments and an overall reduction of immunosuppression after transplant. It is not known if this is linked with an immunologic consequence such as higher rejection rates or development of donor specific antibody (DSA).

Methods: This was a single center, retrospective, 2:1 matched cohort study. Patients were matched for transplant date within 1 year, age at transplant within 5 years, and sex. Patients who survived less than 1 year post-transplant were excluded. Data were collected for 1 year post-transplant on all patients, with the exception of one short telomere patient and two matched controls who had not yet reached the one-year mark. Primary outcomes were median number of calcineurin inhibitor (CNI) target trough reductions and anti-metabolite dose reductions. Additional outcomes included number of patients experiencing severe anemia (hemoglobin < 8 grams per deciliter), leukopenia (white blood cell count < 3000 cells per cubic millimeter), neutropenia (absolute neutrophil count < 1000 cells per microliter), thrombocytopenia (platelet count < 100,000 per microliter), biopsy proven rejection (BPAR), and development of DSA.

Results: Fifteen patients were included in the study, 5 patients with short telomere syndrome and 10 matched controls. Baseline characteristics are summarized in Table 1 and study outcomes in Table 2. There was no difference in the median number of CNI target trough reductions (2 vs. 2.5, p=0.95) or median number of anti-metabolite dose reductions (2 vs. 2.5, p=0.618). While a greater percentage of short telomere patients experienced leukopenia, neutropenia, and thrombocytopenia, it did not reach statistical significance in this small sample. There was no difference in BPAR or DSA.

Conclusions: Short telomere patients did not require significantly more dose adjustments to immunosuppressant medications or experience significantly more adverse effects when compared to non-short telomere patients 1-year post-transplant.

Table 1: Baseline Characteristics

	Short Telomere (n= 5)	Control (n= 10)
Age (median, range)	54 [52-71]	58 [51-69]

Abstract# 818

Unclear Implications of Tacrolimus Time in Therapeutic Range as a Predictor of Acute Rejection in Renal Transplant Recipients Undergoing Early Corticosteroid Withdrawal

D. Pierce, P. West-Thielke, Z. Hajjiri, S. Gaitonde, I. Tzvetanov, E. Benedetti, A. Lichvar, *University of Illinois at Chicago, Chicago, IL*

Purpose: Tacrolimus (TAC) demonstrates a wide intra- and inter-patient variability (IPV) necessitating therapeutic drug monitoring. The purpose of this study is to determine the impact of tacrolimus time in therapeutic range (TTR) in renal transplant (RT) recipients undergoing early corticosteroid withdrawal (ECSWD).

Methods: Adult RT recipients at University of Illinois Hospital & Health Sciences System between 1/1/2015 - 12/31/2018 were included. Patients were excluded if they underwent ABO incompatible RT, positive flow crossmatch RT, died <90 days post-RT, were lost to follow-up <12 months post-RT, and deviated from standard institution protocol. TAC TTR was calculated using the Rosendaal method with protocol goal TAC levels (erroneous levels were excluded). High TTR (TTR-H) was defined as ≥75% based on the median of the cohort. Primary outcome was to compare the incidence of acute rejection (AR) between TTR-H and low TTR (TTR-L) 12 months post-RT. Secondary outcomes included comparing the incidence of donor-specific antibodies (DSA) and *de novo* DSA (dnDSA) and eGFR. Multivariate analyses were conducted to assess risk factors for dnDSA formation and AR.

Results: Demographics are represented in Table 1. Acute rejection rates were similar between groups (TTR-H 20.4% vs TTR-L 18.9%, p=0.799). Rejection subtype, DSA, and eGFR comparisons are detailed in Table 2. Positive DSA post-transplant (OR 3.62 95% CI 1.41 - 9.26, p=0.007) was associated with a higher AR at 12 months post-RT (Table 3). Mycophenolate dose reduction/discontinuation (OR 2.82 CI

95% 1.13 - 6.97, p=0.025) and AR (OR 2.99, 95% CI 1.09 - 8.18, p=0.032) were associated with increased dnDSA formation within 12 months of RT. Tacrolimus TTR did impact AR or dnDSA formation in univariate or multivariate modeling.
Conclusions: In an ECSWD population, there was no difference in AR 12-months post-RT between TTR-H and TTR-L. There was a higher incidence of DSA at 1-year post-transplant in those with reduced mycophenolate dosing and history of acute rejection. Ideal population utility of tacrolimus TTR remains to be defined in RT with future studies.

Table 1. Demographics

	Overall (n=193)	High TTR (n=98)	Low TTR (n=95)	p-value
Age at transplant, mean (SD)	51.7 (±13.2)	51.7 (±12.5)	51.8 (±13.9)	0.829
Male, n (%)	133 (68.9)	73 (74.5)	60 (63.2)	0.089
Black race, n (%)	100 (51.8)	47 (48)	53 (55.8)	0.276
BMI >35 kg/m2, n (%)	73 (37.8)	40 (40.8)	33 (34.7)	0.384
Repeat transplant, n (%)	11 (5.73)	4 (4.1)	7 (7.4)	0.333

Abstract# 819

Impact of the Transplant Clinical Pharmacist in an Outpatient Transplant Clinic

O. Roe[1], S. Gattis[1], R. Parsons[2], D. Lo[2], S. Todd[1], *[1]Emory University Hospital, Atlanta, GA, [2]Emory Transplant Center, Atlanta, GA*

Purpose: Pharmacist involvement in the outpatient transplant clinic setting has been correlated with improved patient outcomes in single organ cohort studies. Direct clinical pharmacist involvement began in the outpatient transplant clinic at our institution in early 2018. Our study aim was to evaluate the impact of transplant clinical pharmacists' interventions within a multi-organ post-transplant clinic.
Methods: Patients discharged from their transplant admission between August 1, 2016 and August 1, 2019 were reviewed. Patients were placed in one of two cohorts based on the presence or absence of a transplant pharmacist outpatient note within 30 days of transplant discharge in addition to receiving standard provider follow up. Patients in each cohort were matched 1:1 by organ type. The primary outcome of this study was to determine the probability of any all-cause hospital encounter 90 days post-transplant discharge. Secondary endpoints included hospital admission encounters, emergency department encounters, biopsy confirmed organ rejection, blood pressure, blood glucose, protocol-driven prophylactic medication renal dosing, and all-cause mortality.
Results: During the study period, a total of 600 patients were evaluated with 300 included in each cohort. The study population included higher risk patients: 508 (84.7%) pretransplant hypertension, 272 (45.3%) pretransplant diabetes mellitus, average age 51.9 ± 11.8 years. One hundred and forty-six patients (48.7%) in the pharmacist cohort experienced a hospital encounter in comparison to 154 patients (51.3%) in the control group (p=0.513). Appropriate renal dosing of prophylactic medications was significantly higher in the pharmacist cohort at 30, 60 and 90 days (p=0.032, p=0.009, p=0.002). Selected additional secondary outcomes are listed in table 1.
Conclusions: All-cause hospital encounters 90 days post-transplant did not differ between groups. Clinical pharmacist involvement in the outpatient transplant setting is associated with a significantly higher rate of appropriate renal dosing of standard prophylactic medications. Additional analysis of hospital encounters is warranted to further elucidate differences between groups. Prospective cohort studies of transplant clinical pharmacist interventions are needed.

Table 1. Selected Secondary Outcome Results			
	Pharmacist (n=300)	Control (n=300)	p-value
Hospital admission	40.3% (n=121)	44% (n=132)	p=0.363
Emergency department visit not resulting in admission	15.7% (n=47)	15.3% (n=46)	p=0.91
Biopsy confirmed rejection	14% (n=42)	15.7% (n=47)	p=0.566
Death	0.3% (n=1)	0.7% (n=2)	p=1

Abstract# 820

Evaluation of Safety and Efficacy of PCSK9 Inhibitors in Solid Organ Transplant Recipients: Experience at a Large Multi-organ Transplant Center

A. Ucci[1], M. Norris[2], J. Trofe-Clark[2], T. Fallah[2], M. Meck[1], R. Samudralwar[1], M. V. Genuardi[3], *[1]Hospital of Univ of Pennsylvania, Philadelphia, PA, [2]Penn Transplant Institute, Hospital of Univ of Pennsylvania, Philadelphia, PA, [3]Cardiovascular Medicine Div, Hospital of Univ of Pennsylvania, Philadelphia, PA*

Purpose: The aim of the study was to characterize the efficacy and safety of proprotein convertase subtilisin/kexin type 9 (PCSK9) inhibitors in solid organ transplant recipients (SOTR).
Methods: This retrospective study included SOTR age ≥18 yrs who used a PCSK9 inhibitor for at least 4-wks post-transplant with at least 1 lipid panel available. Heart, lung, kidney, and liver transplant recipients who were transplanted between Jul 1,1990-2020 were included. Data collection ended on Oct 31, 2020, and included SOTR demographics, atherosclerotic cardiovascular disease (ASCVD) history, rejection, graft loss, and death in the 6 months following PCSK9 initiation. The primary efficacy outcome was change in LDL and total cholesterol (TC) from baseline to 6 months. The primary safety outcome was incidence of presumed or proven rejection. Secondary endpoints included change in calcineurin inhibitor (CNI) or mammalian target of rapamycin (mTOR) troughs or doses and incidence of ASCVD in the 6 months after PCSK9 initiation.
Results: Nineteen SOTRs were included. Mean age was 56 yrs (±11.8) and SOTRs were primarily males (63.2%) and white (84.2%). 52.6% of SOTRs were followed for 6 months. Transplanted organs included kidney (42.1%), heart (31.6%), liver (21.1%), and lung (5.3%). Median time from transplant to PCSK9 initiation was 4.6 yrs (IQR 0.84-16.4). Twelve were initiated on evolocumab and 7 on alirocumab. Over half (52.6%) were on concomitant statin therapy. Significant reductions in TC and LDL were observed upon initiation of PCSK9 therapy (Table 1). Immunosuppression regimens consisted of tacrolimus (89.5%), cyclosporine (5.3%), and sirolimus (5.3%). No significant changes in CNI or mTOR troughs or dosing were observed. New ASCVD events occurred in 15.7% of SOTRs. All had a prior history of ASCVD, 2 had an myocardial infarction and a 3rd required stent placement for occluded coronaries. No episodes of rejection, graft loss, or death occurred during the study period.
Conclusions: PCSK9 inhibitor use in SOTR appears to be efficacious and safe. No episodes of rejection or changes in immunosuppression dosing or CNI or mTOR troughs were observed during the study. Further research on the longitudinal effects of PCSK9 therapy in SOTR is warranted.

Table 1				
Parameter Evaluated	Baseline (Mean ± SD)	6 months (Mean ± SD)	Mean Change (Mean ± SD)	p-value
LDL (mg/dL)	106.9 ± 55.6	39.8 ± 19.7	80 ± 50.2	**0.033**
Total Cholesterol (mg/dL)	195.3 ± 64.4	128.2 ± 34.0	76.2 ± 67.1	**0.012**
Tacrolimus trough (mcg/L)	7.1 ± 1.9	9.5 ± 5.0	2.0 ± 4.0	0.126
Tacrolimus dose (mg/day)	5.3 ± 4.1	5.2 ± 4.0	0.0 ± 1.7	1.000

Abstract# 821

Letermovir Prophylaxis in Solid Organ Transplant - CMV Breakthrough and Tacrolimus Drug Interaction

R. Winstead[1], D. Kumar[1], A. Brown[1], I. Yakubu[1], C. Song[1], L. Thacker[2], G. Gupta[1], *[1]Virginia Commonwealth University Health, Richmond, VA, [2]Virginia Commonwealth University, Richmond, VA*

Purpose: Valganciclovir is the preferred drug for cytomegalovirus (CMV) prophylaxis in solid organ transplantation. A limitation to its use is profound myelosuppression. Letermovir is a new agent approved for CMV prophylaxis in hematopoietic stem cell transplantation and is associated with less toxicity. This study aims to assess the effectiveness and safety of letermovir in solid organ transplantation.

Methods: A single-center, matched cohort study was performed on 31 transplant recipients who were converted from valganciclovir to letermovir from November 2017 to June 2020. The primary outcome was the rate of CMV breakthrough infections while on prophylaxis. Secondary outcomes included rate of leukopenia, doses of immunosuppression, rejection, non-CMV infection, and renal function. Statistical analyses of continuous variables included the student's t-test, ANOVA test, and Wilcoxon Signed Rank test. Categorical data were analyzed with chi-square test and Fisher's Exact test.

Results: There was no difference in the rate of CMV breakthrough between patients on letermovir (8.7%) and valganciclovir (13.5%), (p = 0.7097). After conversion to letermovir, patients required lower tacrolimus doses at -3.34 mg (Std Dev-1.3, p=0.0273), between conversion and day 7. The median difference in tacrolimus trough concentrations from conversion to day seven was 9.1 ng/mL [4.9, 16.95] (P=0.0002). Leukopenia improved by 1.8 10^9/L [1.08, 4.85] (p<0.0001).

Conclusions: Patients converted from valganciclovir to letermovir did not show an increased rate of CMV breakthrough compared to a historical, matched cohort of patients remaining on valganciclovir. A significant drug interaction was noted with tacrolimus, leading to a recommendation to reduce the dose by 40-50% upon initiation of letermovir.

Abstract# 822

The Impact of Tacrolimus IPV and TTR on the Development of De Novo Donor-specific Antibodies in Kidney Transplant Recipients

D. Xu[1], K. Richards[1], K. Zheng[1], H. Patel[2], F. Cardarelli[2], J. A. Pena[3], A. Aala[2], *[1]Pharmacy, Beth Israel Deaconess Medical Center, Boston, MA, [2]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA, [3]Pathology, Beth Israel Deaconess Medical Center, Boston, MA*

Purpose: High intrapatient variability (IPV) and low time in therapeutic range (TTR) of tacrolimus (TAC) may increase the risk of developing de novo donor-specific antibodies (dnDSA) among transplant recipients. The purpose of the study was to assess: (1) mean IPV and TTR between patients who developed dnDSA versus patients who did not (control), 2) rates of biopsy proven rejection, and 3) death-censored graft loss.

Methods: This is a retrospective, single center chart review of 51 adults who underwent renal transplantation between January 2014-December 2018. All patients had 2 years of post-transplant follow-up data available. Induction and maintenance immunosuppression is described in Table 1. Patients were excluded if they failed to undergo DSA screening post-transplant or received a multi-organ transplant. Methods for calculations of IPV and TTR are summarized in Figure 1.

Results: Patients who did not develop dnDSA "Control" (n=38) and those who developed dnDSA (n=13) were compared. Baseline characteristics are described in Table 2. Based on institutional protocol, the majority of patients received rATG and approximately half underwent steroid withdrawal. The mean IPVs and TTRs were not statistically significant when comparing the 2 groups, but there was a trend towards significance for TTRs at 12 months (55.6±19.6 vs 45±21.7, p=0.08) (Table 3 and 4). Rates of biopsy proven rejection were significantly higher in the dnDSA group (38.5% vs 5.2%, p=0.008). 1 patient in dnDSA group experienced death-censored graft loss due to antibody mediated rejection. When evaluating IPV and TTR of patients who developed dnDSA and rejection, the results were concurrent with current literature (Table 5).

Conclusions: Mean IPVs between control and dnDSA groups were not significantly different at all time points. Although the differences in TTR did not reach statistical significance, patients in the dnDSA group had a trend towards lower TTR. This suggests that TTR may have more impact than IPV in predicting dnDSA development following renal transplantation.

Better Dialysis Facility Five-Star Rating is Associated with Increased Listing for Kidney Transplantation

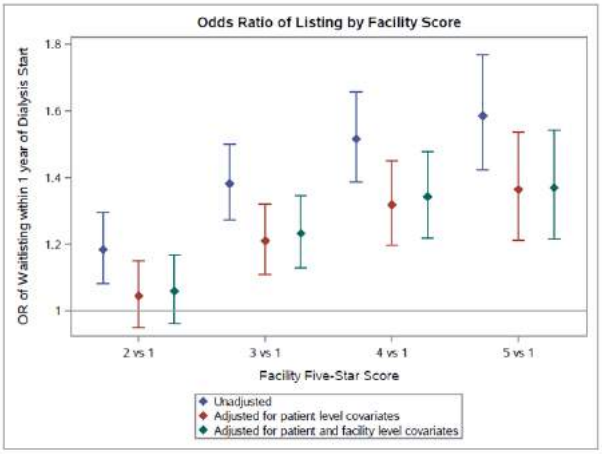
J. T. Adler[1], L. Xiang[1], J. S. Weissman[1], J. R. Rodrigue[2], R. E. Patzer[3], S. S. Waikar[4], *[1]Surgery, Brigham and Women's Hospital, Boston, MA, [2]Surgery, Beth Israel Deaconess Medical Center, Boston, MA, [3]Surgery, Emory University, Atlanta, GA, [4]Medicine, Boston Medical Center, Boston, MA*

Purpose: Improving the quality of dialysis care for patients with end stage kidney disease (ESKD) is a national clinical and policy priority: the Advancing American Kidney Health (AAKH) executive order established a target of 80% of new patients with ESKD receiving home dialysis or a kidney transplant by 2025. The Centers for Medicare & Medicaid Services (CMS) Five-Star Quality Rating is a public reporting program developed to help patients evaluate the quality of their dialysis center; it remains unknown if access to higher quality dialysis centers is related to higher likelihood of listing for transplant, which would help achieve the goals of AAKH. Therefore, empirical data would be helpful to assess whether increasing access to higher quality dialysis centers would potentially improve transplant listing rates.

Methods: Using the incident cohort of patients beginning dialysis in 2013 from the United States Renal Data System, rates of listing for transplant within one year were

assessed. Dialysis facility Five-Star Quality scores were obtained from Medicare Dialysis Facility Compare. We analyzed crude listing rates by Five-Star Quality ratings, and then estimated the probability of listing for transplant using a logistic regression model that controlled for patient- and facility-level factors.

Results: Of the 100,740 incident dialysis patients, 7,851 (7.8%) were listed for transplantation within 1 year. Patients undergoing dialysis at 5-star dialysis centers were more likely to be listed than patients at the 1-star dialysis centers (9.2% vs 6.0%, P<0.001). Adjusting for both patient- and facility-level covariates, the odds of patient listing within 1 year were higher at 5 vs 1 star facilities (OR 1.40, P<0.001, Figure). Patients from rural (OR 0.81, P<0.001), for-profit (OR 0.69, P<0.011), and large (OR 0.81, P<0.001) dialysis facilities were less likely to be listed.



Conclusions: There was a significant association between better dialysis facility quality, as measured by the CMS Five-Star Quality Ratings, and higher likelihood of listing for transplantation. Increasing patient access to higher quality dialysis facilities may increase access to transplantation and achieve the goals of AAKH.

Abstract# 687

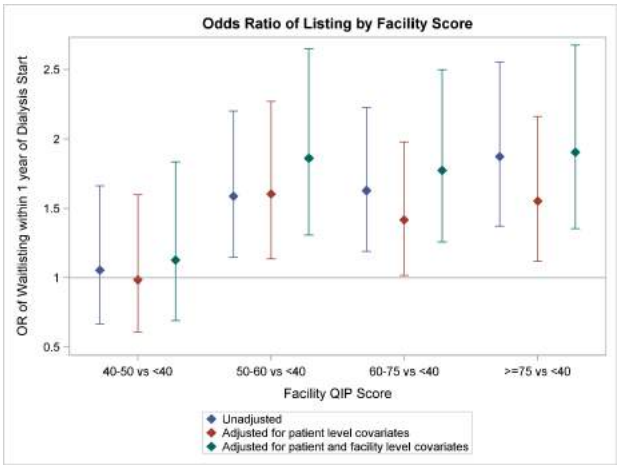
The Quality Incentive Program (QIP) is Associated with Increased Waitlisting for Transplantation

J. T. Adler[1], L. Xiang[1], J. S. Weissman[1], J. R. Rodrigue[2], R. E. Patzer[3], S. S. Waikar[4], T. C. Tsai[1], *[1]Surgery, Brigham and Women's Hospital, Boston, MA, [2]Surgery, Beth Israel Deaconess Medical Center, Boston, MA, [3]Surgery, Emory University, Atlanta, GA, [4]Surgery, Boston Medical Center, Boston, MA*

Purpose: The Centers for Medicare & Medicaid Services (CMS) introduced the Quality Incentive Program (QIP) in 2012, a pay-for-performance program which penalizes dialysis centers payments up to 2% based on performance on publicly reported quality measures of clinical outcomes, safety reporting, and care coordination. It is unknown if these ratings translate to improved access to transplantation, defined as listing within 1 year of dialysis start.

Methods: Using the incident cohort of patients beginning dialysis in 2013 from the United States Renal Data System, patients were followed for one year to assess 1-year transplant listing rates. Dialysis facility QIP scores were obtained from Medicare Dialysis Facility Compare. We analyzed unadjusted 1-year listing rates by levels of QIP score. Using a multivariable logistic regression model that controlled for patient and facility-level factors, we then assessed the relationship between quality as measured by QIP performance and 1-year listing rates. QIP scores < 40 lead to a payment reduction of at least 1.5%.

Results: There was a significantly higher unadjusted rate of listing for transplantation at higher performing centers (8.1 vs 4.5%, ≥75 vs <40, P<0.001). In analyses adjusted for patient- and facility-level covariates, the odds of listing were higher at QIP score ≥75 vs <40 facilities (OR 1.90, P<0.001). Patients from urban (OR 1.23, P<0.001), non-profit (OR 1.37, P<0.001), and small (OR 1.25, P<0.001) dialysis facilities were more likely to be listed within 1 year.



Conclusions: There was a significant association between better dialysis facility quality, as measured by the QIP score, and higher likelihood of listing for transplantation. Given the national policy goal of increasing listing transplantation, 1 year listing rates could be considered as part of the QIP metric to incentivize dialysis center referral to transplant centers.

Abstract# 688

Dual Liver and Kidney Donors, What Makes Them Decide to Do It?

H. Al Harakeh, B. Emmanuel, C. Hughes, A. Tevar, J. Steel, A. F. DiMartini, S. Ganesh, A. Humar, *Surgery, University of Pittsburgh Medical Center, Pittsburgh, PA*

Purpose: There is incongruity between the transplant waiting list and the number of deceased donors available, therefore there is an enduring challenge to increase the number of living donors. On the other hand, there are nearly 60 intriguing living donors who donated more than one solid organ so far in the US. 17 of these donors donated at our center. We looked at those patients' charts and tried to learn how they made that decision.

Methods: Using our divisional database a retrospective chart review was done on all donors who donated a liver and a kidney. Data regarding reasons for donation, altruism, and complications were abstracted.

Results: 17 patients donated two organs, a liver and a kidney, at different times. Nine of the patients (53%) were males. Six (35%) were residents of Pennsylvania and the others came from different states. Eleven (65%) patients identified themselves as believers and six (35%) did not associate themselves with any religion. Nine of the patients (52%) were either married or had a long term relationship. Nine (53%) had children, and 15 (88%) had at least one parent alive. 13 (76%) had a Bachelor degree or higher. 14 (83%) consumed alcohol either socially or moderately and three did not. Four of our patients (24%) had depression, one of whom with suicidal ideation. The four were diagnosed, received pharmacologic treatment and cleared by our psychiatrists for the surgeries prior to donation. Eleven of the patients (65%) donated the kidney before the liver. The average age at the first donation was 39 years and the average time between both surgeries was 3.8 years. Twelve patients (71%) were altruistic donors at the first donation, and three of the five non-altruistic donors in the first donation became altruistic in the second. Some of the reasons for donating were "after losing his son to brain cancer", "good experience with his previous kidney donation", "after knowing that one can do it again". Major complications happened in three patients. One of them was an intraabdominal abscess that happened after the second donation which was a kidney. The second underwent incisional hernia repair after the first donation which was a liver and after the second which was a kidney. The third patient had an exploratory laparotomy for obstruction four days after his second donation which was a liver. Adhesion bands from the previous kidney trocar sites were the culprit. All 17 donors are still alive and had an otherwise uncomplicated postoperative course.

Conclusions: Factors like previous good experience in donation and the knowledge that it can be done helped in the decision making for some donors to donate for the second time. More research is needed on this topic to help assess the safety of dual donation and to help advocate additional donating.

Abstract# 689

Impact of Electronic Donor Referral Technology on Deceased Donor Referrals

B. Boyarsky[1], J. R. DiRito[2], K. Vanterpool[1], J. Piano[3], W. Liu[3], J. Hewlett[4], C. Trahan[4], D. Segev[1], M. Levan[1], A. Massie[1], P. Niles[4], *[1]Johns Hopkins, Baltimore, MD, [2]Yale, New Haven, CT, [3]Transplant Connect, Santa Monica, CA, [4]Southwest Transplant Alliance, Dallas, TX*

Purpose: Hospitals likely fail to refer many medically eligible potential deceased donors to OPOs. As such, increasing eligible referrals may increase the donor pool. We hypothesized that implementation of iReferral[SM], an automated and electronic referral platform, would be an effective method of circumventing the challenges faced with the current phone-based referral system.

Methods: To better understand the impact of the iReferral[SM] system on referrals, we conducted a retrospective study of all deceased donor referrals (n=1409) to three Texas hospitals January 2016 - August 2020. We used Poisson regression to analyze changes in the number of referrals following deployment of the iReferral[SM] system in October 2018, overall and for various subgroups, adjusting for seasonality and secular trends.

Results: After implementation of iReferral[SM], the number of patient referrals increased from median (IQR) 14 (12-18) to 36 (31-43) (p<0.001), representing a 70% total increase per month (IRR $_{1.38}$ 1.70 $_{2.10}$ p<0.001) (Figure 1). This increase was seen across various subgroups including patients <50 (IRR $_{1.07}$ 1.73 $_{2.81}$ p=0.02) and >50 years old (IRR $_{1.36}$ 1.72 $_{2.16}$ p<0.001), and brain dead patients (IRR $_{1.43}$ 1.76 $_{2.16}$ p<0.001). Median (IQR) hours from admission to referral decreased from 60 (13-157) to 30 (7-152) (p<0.001). The number of patients whose families were approached for consent doubled (IRR $_{1.12}$ 2.03 $_{3.65}$ p=0.02). The number of donors per month was 26% higher than pre-iReferral[SM], though the difference was not statistically significant (p=0.3).

Conclusions: After the implementation of an automated and electronic donor referral, the rate of deceased donor referrals increased substantially, and the number of patients whose families were approached for consent doubled. Automating the process at these key upstream steps in the deceased donor process may increase hospital and OPO efficiency and donor referrals.

Figure 1. Number of deceased donor referrals per month (1a) and number of families approached for consent per month (1b) before and after the implementation of iReferral[SM] automated donor referral technology

Abstract# 690

Realistic Targets for Transplantation Among Incident Kidney Failure Patients in the United States

S. Brar, M. Kadatz, J. Lan, D. Chang, J. Gill, S. Vaishnav, J. Gill, *University of British Columbia, Vancouver, BC, Canada*

Purpose: The Executive Order on Advancing American Kidney Health aims to treat 80% of all kidney failure patients with transplantation or home dialysis but no targets for transplantation were advanced.

Methods: We studied incident kidney failure patients 18-70 years of age in the United States between 2015 and 2016 to determine the proportion treated by transplantation by state of residence. Patients were followed from the date of first chronic kidney failure treatment for 3.5 years for the outcome of transplantation from any donor source with death treated as a competing risk.

Results: The figure shows the incidence of transplantation overall and stratified by patient age. In each age group, the incidence of transplantation in the 10 states with the highest use of transplantation is shown to indicate a feasible target for transplantation. The incidence in states with intermediate use and and lowest use of transplantation is shown to demonstrate the opportunity to increase transplantation. Only 11% of patients aged 18-70 years were treated with transplantation within the first 3.5 years of developing kidney failure with 19% of patients in the top ten performing states and 7% in the bottom ten performing states treated with transplantation. Treatement with transplantation was inversely related to patient age: 18-40 years (overall 23%, top 10 states 39%, bottom ten states 14%); 41-60 years (overall 12%, top 10 states 21%, bottom 10 states 7%); 61-70 years (overall 7%, top 10 states 12%, bottom 10 states 4%).

Conclusions: We conclude that a realistic target for treatment with transplantation among patients aged 18-70 years is 20% after 3.5 years of a kidney failure diagnosis.

Abstract# 691

Racial/ethnic Disparities Among Renal Transplant Recipients with Diabetes, Hypertension, and/or Dyslipidemia Due to Medicare Part D Star Ratings Criteria

M. Chisholm-Burns[1], C. Spivey[1], C. Tsang[1], L. E. Hines[2], J. Wang[1], *[1]University of Tennessee Health Science Center College of Pharmacy, Memphis, TN, [2]Pharmacy Quality Alliance, Alexandria, VA*

Purpose: Medication adherence is critical to positive outcomes in renal transplant recipients (RTRs), and policies have been designed encouraging adherence. For example, Medicare Part D Star Ratings of quality of health and drug services received by individuals enrolled in Medicare Advantage (MAPD) and Prescription Drug plans promote positive outcomes and are associated with incentives including federal bonus payments made to MAPDs and possible increases in plan enrollment. Medication adherence measures for diabetes (DM), hypertension (HTN; renin-angiotensin system antagonists), and cholesterol (statins) are the only 3 medication utilization measures considered for plan ratings in the Part D Star Ratings system in 2018. Methods to calculate Star Ratings may contribute to racial/ethnic disparities, causing MAPDs to focus on certain patients meeting Star Ratings inclusion criteria, and possibly disincentivizing needed services/programs to those who do not meet criteria. The study objective is to determine if measurement of Star Ratings adherence metrics among RTRs with DM, HTN, and dyslipidemia (DLD) lead to racial/ethnic disparities.

Methods: This was a cross-sectional analysis of 305,077 adult RTRs with Medicare claims between 2010 and 2016, and receiving continuous coverage of Medicare Parts A/B/D and alive in 2017. Utilizing 2017 Medicare claims linked to Area Health Resources Files, inclusion in measure calculation was determined based on inclusion/exclusion criteria in metrics for adherence to DM, HTN, and cholesterol medications in Star Ratings. Logistic regression and multinomial logistic regression were used to calculate odds ratios (ORs), relative risk ratios (RRRs) and adjust for patient/community characteristics.
Results: Compared to non-Hispanic White RTRs, minorities were less likely to meet criteria to be included in calculations for Star Ratings adherence measures. Among RTRs with DM, adjusted ORs for inclusion of Black, Hispanic, and Asian/Pacific Islander RTRs were 0.56 (95% Confidence Interval [CI] 0.53 - 0.60), 0.53 (95% CI 0.50 - 0.57), and 0.69 (95% CI 0.63 - 0.76), respectively. Findings were similar among RTRs with HTN and DLD. Among individuals with 2 or 3 chronic conditions, minorities were likely to be included in the calculation of fewer measures than their White counterparts. For example, among individuals with all 3 conditions, adjusted RRRs for Black compared to White RTRs for being included in calculation of 3, 2, or 1 measure were 0.31 (95% CI 0.27 - 0.36), 0.41 (95% CI 0.36 - 0.46), and 0.46 (95% CI 0.37 - 0.56), respectively.
Conclusions: Disparities exist among RTRs with DM, HTN, and/or DLD qualifying for inclusion in Star Ratings measures. Racial/ethnic minorities are less likely to be included compared to White patients, potentially creating health disparities and adverse outcomes.

Abstract# 692

The Use of Organs from Donors That Do Not Meet Eligibility Criteria in the United States

L. Deroos, M. Lavieri, D. Hutton, W. Marrero, N. Parikh, *University of Michigan, Ann Arbor, MI*

Purpose: Increasing the number of organs available for transplantation could reduce waitlist morbidity and mortality for patients with end organ failure. Most transplanted organs come from donors meeting an organ-specific eligibility definition prescribed by the OPTN. However, many successful transplants involve donors who do not meet all criteria (i.e."ineligible" donors). We aimed to analyze survival differences between recipients of eligible and ineligible organ donations and model the impact of increased ineligible donor use.
Methods: We combined OPTN STAR file data with OPTN-provided data of all eligible deaths from 2008-2017. We fit Kaplan-Meier survival curves for eligible and ineligible solid-organ donation recipients and compared survival outcomes via log rank tests. We used Cox regression to study the association of eligibility with survival when controlling for patient characteristics (e.g. sex, age, BMI, etc.). Finally, we estimated life-years gained had OPOs increased ineligible donor utilization rates to the 75th percentile.
Results: 77,576 adult donors met inclusion criteria. Figure 1 shows patient survival by organ and donor eligibility. Recipients of ineligible kidney, lung, and pancreas donations had no significant difference in survival compared to eligible donations (p=0.24, 0.49, 0.86, respectively). Heart and liver transplants using ineligible donors saw an 8.5% (p=0.03) and 3.6% (p<0.01) reduction in 5-year survival, respectively. When accounting for patient characteristics, donor eligibility had a significant positive association with survival (hazard ratio: 1.14; 95% CI: (1.10, 1.18); p<0.01). Across OPOs, ineligible donor use ranged from 5%-39% of donors. Had OPOs increased ineligible donor use to meet the 75th percentile, 9,450 additional organs would have been available for transplant over the 10-year period, enabling an estimated 51,786 additional life-years saved.
Conclusions: Using organs from ineligible donors offers a survival benefit for waitlisted candidates who may otherwise never receive a transplant. Heart and liver recipients have decreased relative survival with ineligible compared to eligible donor use, however improving utilization can improve the number of organs available for transplantation. Further analyses defining ineligible donors that yield optimal recipient outcomes are warranted.

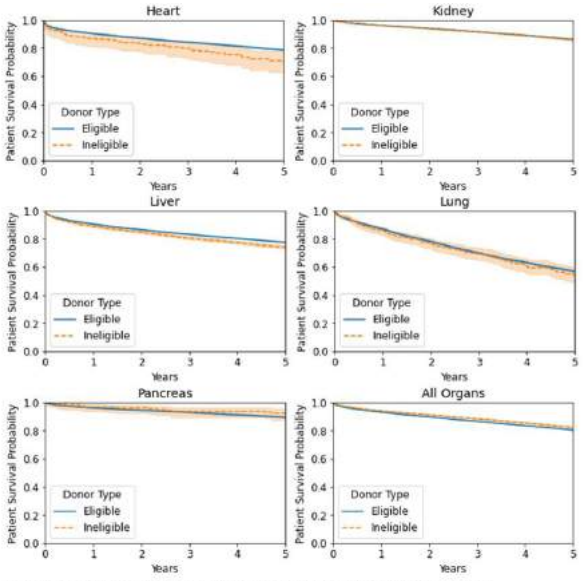

Figure 1: Kaplan-Meier curves of transplant recipient survival by organ and donor eligibility.

Abstract# 693

Trends in Living Donor Transplantation in USA

N. Kemmer, C. Albers, S. Agrawal, R. Syed, M. Malespin, J. Buggs, *Tampa General Hospital, Tampa, FL*

Purpose: Globally, living donation has improved access to organ transplantation and saved the lives of individuals with end-stage kidney disease and end-stage liver disease. In the USA, the increasing prevalence of end-stage disease has resulted in widening gap in organ supply and demand. In the last decade, several allocation policies have been implemented by UNOS (United Network for Organ sharing), with the goal of maximizing donor availability, improving access and expanding the donor pool. However, the contribution of living donation on the donor pool is uncertain. Therefore, the Aim of this study is to evaluate the trend of living donation in the changing landscape of Abdominal Transplantation.
Methods: Using the UNOS database, we identified all adult candidates (≥ 18 years) who underwent solid organ transplant (Liver, Kidney) in the last decade (2010 - 2019). Data extracted included Type of Transplant (Living vs. Deceased), Recipient demographics including age, gender, ethnicity and race. Chi-square tests and ANOVA tests were used for comparative analysis.
Results: During the study period, 244,844 underwent transplant (178,125 Kidney and 66,719 Liver). Among the Kidney recipients 31.8% were living donor with 62% male and among Liver recipients 4.0 % were living donor with 55% male. Although overall there was an increase in total annual transplant (living and deceased) for both kidney (16,152 to 23,641) and liver (5731 to 8,345), there was a significant variation in proportion of living donor transplantation. We found a decline in living donor kidney transplant (LDKT) but a paradoxical increase in living donor liver transplant (LDLT). See Figure 1. With the exception of Asian group, a significant decline in LDKT was found among non-Asian (Black, Caucasian and Hispanic) in comparison to an increase in LDLT recipients. Among Asian recipients we found an increase in LDKT (27% to 33%, p=0.005) but a trend towards a decline in LDLT though this was not significant (4.1 % to 3.6%, p= 0.62).
Conclusions: The current study showed that in the last decade (2010 - 2019), there has been a significant decline in adult LDKT with a corresponding relative increase in LDLT. With the ongoing shortage of available deceased donors and the proven comparable outcomes with living donor transplantation (liver, kidney); future studies focused on identifying barriers to living donation are warranted. Furthermore, public health policies aimed at increasing awareness and education about living donation will be invaluable

Abstract# 694

Attitudes Regarding Transplantation During the Pandemic: Give Me My Kidney Now!

T. Menser[1], M. Hobeika[2], A. Gaber[2], H. Ibrahim[2], *[1]Houston Methodist Research Institute, Houston, TX, [2]Houston Methodist Hospital, Houston, TX*

Purpose: The transplant community faces ongoing challenges regarding the conduct of organ transplantation during the COVID-19 pandemic, and patient treatment preferences during the pandemic require consideration.
Methods: To determine waitlisted end-stage kidney disease patients willingness to accept an organ during the pandemic, we conducted an online survey of patients with available email addresses (n=1068); responses were received between May 29 and July 2, 2020.Patients were asked 12 questions, including two open-ended question to understand any concerns related to 1) quality and source of donor kidney and 2) impact of COVID-19 on kidney transplantation in general.
Results: The majority of respondents indicated they would accept an organ during the pandemic and respondents almost universally indicated their comfort with transplant if their physician thought they should. Table 1 shows the questions and the aggregated responses; the response rate was 22% (n=232, with an average response per question of 76% (n=176). There were 113 responses to the open-ended questions that were classified into following emergent themes: "clinical concerns", "COVID concerns", "trust", and "no concern" if the latter was explicitly stated, with a fifth category for "other" responses. The open response comments highlighted candidates' concerns about the pandemic lengthening their wait time, contracting COVID-19 after transplantation, and balancing risk of infection versus remaining on the list (Table 2).
Conclusions: These results indicate that kidney transplant candidates heavily support continued transplantation during the pandemic, suggesting that patients may perceive the need for transplantation to outweigh the risks associated with COVID-19. Balancing patient treatment preferences with clinical capacity (e.g., testing availability, personal protective equipment, and overall hospital beds) requires ongoing reassessment in the face of fluctuating incidence of COVID-19.

Table 2 – Representative Quotes from Waitlisted Kidney Patients
Clinical Concerns
"Worried about not getting to go to the doctor during COVID-19. Worried that the wait for a donor kidney will be even longer now. Worried about catching COVID-19 in the hospital and/or clinic."
"I am concerned about the challenges post transplant. The immune system is medically suppressed to reduce rejection risk."
COVID Concerns
"Right now the risk of dying from COVID in Texas is .00005%. What is the risk of me dying if I don't get a kidney soon."
"As long as it's a good working kidney I'm willing to take my chances."
Trust
"I will leave it to Drs. And God amen."
"I would rely on my transplant team decision for me."
No Concerns
"As long as they are disease free, I don't have any."
"No concerns just want a Kidney already 5 years and counting."

Table 1 – COVID-19 Kidney Transplant Treatment Preferences Responses	Yes %
1. I am willing to receive a deceased donor transplant during the COVID pandemic.	80%
2. I am willing to receive a living donor transplant during the COVID pandemic.	92%
3. If a deceased donor kidney becomes available for me during this time I would choose to wait until after the COVID pandemic.	27%
4. If a living donor volunteers to donate a kidney to me during this time I would choose to wait until after the COVID pandemic.	17%
5. I am willing to receive a transplant at this time but only from a donor who has tested negative for the COVID virus.	81%
6. I am willing to receive a transplant at this time, but only with a highest-quality kidney (from a young and healthy donor).	57%
7. I am willing to receive a transplant at this time from any donor as long as my doctor thinks it would be a good kidney for me.	95%
8. I would accept a donor kidney if the risk of dying from potential COVID infection was the same as my risk of death by remaining on dialysis.	61%
9. I would accept a donor kidney regardless of the risk of COVID infection.	36%
10. I trust my transplant team to make the decision about the safety of accepting a kidney at this time.	97%

Abstract# 695

Seasonality of Mortality for Solid Organ Waitlist Candidates

J. Miller, D. Musgrove, *SRTR, Minneapolis, MN*

Purpose: Analysis of the impact of policies or natural occurrences on transplant system outcomes requires comparison of a treatment (post-policy) period to a control (pre-policy) period. Choosing a proper control period requires an understanding of seasonality of outcomes of interest. This study describes seasonality of death on the solid organ transplant waiting lists and compares it to that of the US adult population.
Methods: Using SRTR standard analysis files, mortality rates were calculated for each month from January 1999 to December 2018 for candidates prevalent on each solid organ transplant waitlist at any point in the month. Monthly rates were then standardized as a ratio to the 13-month simple moving average centered on the month to give an interpretation of more deaths (ratio > 1) than the yearly average or fewer deaths (ratio < 1). Linear regression with month as a categorical predictor modeled seasonality of standardized mortality for each organ.
Results: Mortality rates on the kidney, liver, lung, and pancreas waitlists showed statistically significant variation by month. For kidney, liver, and lung, mortality rates were higher in the winter, particularly January and February, and lower in the summer. Pancreas waitlist mortality rates showed broader confidence intervals and a less clear seasonal trend. In comparison, heart waitlist mortality rates were fairly consistent through the year. Seasonal trends in mortality rates for kidney, pancreas, liver, and heart differed significantly from seasonal trends in the US population. In the case of kidney, liver, and heart, seasonal trends were less pronounced than in the general population (Figure 1).
Conclusions: Mortality rates on many solid organ transplant waitlists followed seasonal trends. Analysis of mortality outcomes before and after policy changes or natural experiments should use cohorts matched on time of year. For example, if data after a policy change are available only for January to April of a given year, an appropriate control cohort would most likely be January to April of the previous year.

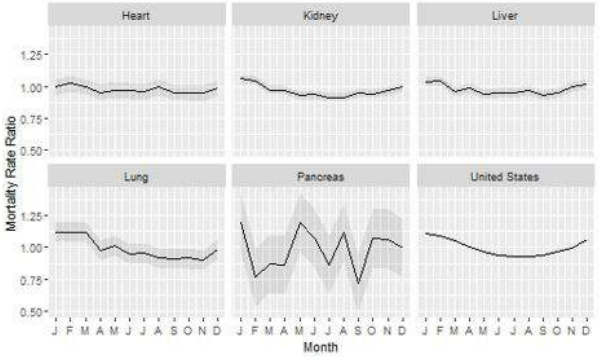

Figure 1. Average solid organ candidate waitlist mortality by month compared with that of the US general population. Curves are averages of monthly mortality rates from 1999 to 2018 standardized to 13-month simple moving averages (95% confidence interval shown in the shaded region).

Abstract# 696

Early Review of Liver Acuity Circles Allocation

S. Noreen[1], J. Heimbach[2], J. Pomposelli[3], M. Cafarella[1], J. Trotter[4], *[1]UNOS, Richmond, VA, [2]Mayo Clinic, Rochester, MN, [3]UCHealth, Aurora, CO, [4]BSWHealth, Dallas, TX*

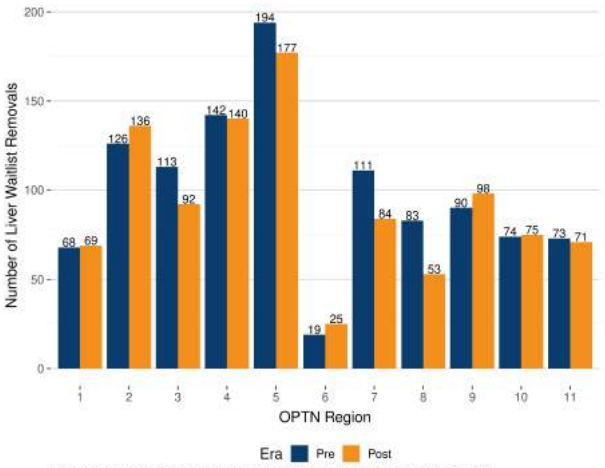
Purpose: Acuity circles (AC) allocation was implemented on February 4, 2020, followed shortly by the declaration of national emergency for COVID-19. The goal of this policy was to broaden distribution of livers, particularly for highly medically urgent candidates.

Methods: OPTN liver waitlist, transplant, and donor data were used. Cohorts of deceased donor liver-alone transplants for the pre- (2/5 - 7/2/2019) and post-eras (2/4 - 6/30/2020), as well as cohorts of liver waitlist registrations added, liver-alone waitlist registrations removed due to death or too sick to transplant, and deceased liver donors during 2/5 - 8/6/2019 (pre-policy) and 2/4 - 8/4/2020 (post-policy) were assessed.

Results: Similar volumes of deceased liver donors were recovered pre- and post-policy (4545 vs. 4564). While 375 fewer new registrations were added to the liver waitlist post-policy largely due to COVID-19, similar numbers of registration removals occurred (1093 pre- vs. 1020 post-policy) (Figure 1). There were fewer transplants overall post-policy (2997 vs. 3140 pre), with similar proportions of recipients with MELD or PELD scores of 29 and higher (51.7% pre- vs. 51.2% post-policy). However, these most medically urgent recipients received livers from farther away post-policy (Figure 2). The variation in median allocation score at transplant, as a measure of disparity across areas, has also decreased by most geographic units (Figure 3).

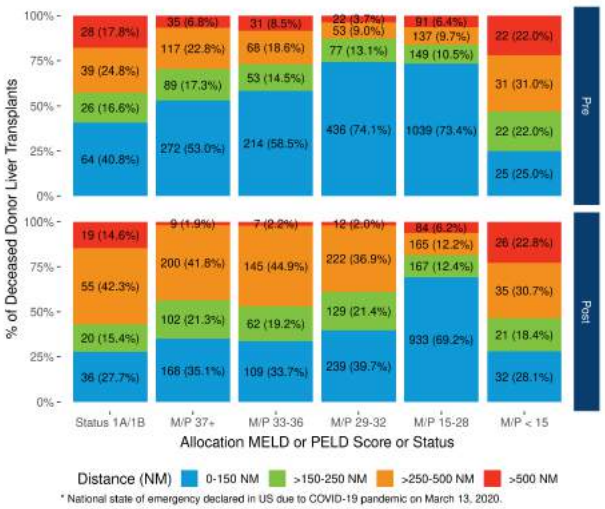
Conclusions: It can already be seen that livers are being more broadly distributed for those with greater medical urgency, and geographic disparities are decreasing. However, the confounding effects of COVID-19 cannot be parsed out from potential policy effects, and continued data accumulation and monitoring of the system by the OPTN Liver Committee will be needed to determine the true effects of this policy change.

Figure 1. Liver-alone waiting list registration removals due to death or too sick to transplant by OPTN Region and policy era



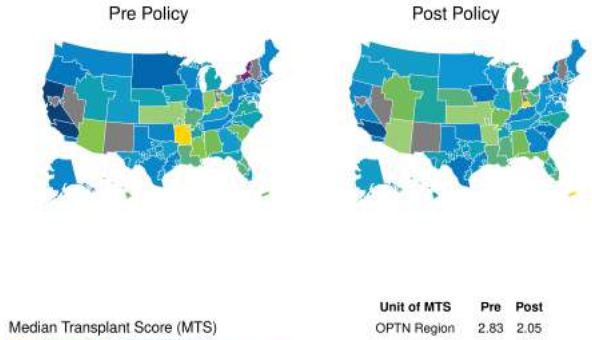
* National state of emergency declared in US due to COVID-19 pandemic on March 13, 2020.
** Candidates may be listed at multiple transplant programs, contributing multiple registrations and thus represent multiple deaths in these counts.

Figure 2. Deceased donor liver-alone transplants by allocation MELD or PELD score at transplant, classification distance, and policy era



* National state of emergency declared in US due to COVID-19 pandemic on March 13, 2020.

Figure 3. Median allocation MELD or PELD score at transplant by donation service area DSA and policy era, with table of standard deviation of median transplant scores by varying geographic units and policy era



Unit of MTS	Pre	Post
OPTN Region	2.83	2.05
DSA	3.71	3.40
State	4.00	3.70
Transplant Center	4.81	4.87

Abstract# 697

Black Disparity in Access to Kidney Transplant Waitlist Worsens in Illinois After New Kidney Allocation System (kas)

S. Park[1], D. Simpson[1], N. Katariya[2], J. Friedewald[3], B. Ho[3], D. P. Ladner[1], *[1]Transplant Outcomes Research Collaborative, Comprehensive Transplant Center, Northwestern University, Chicago, IL, [2]Division of Transplant Surgery, Northwestern University, Chicago, IL, [3]Transplant Nephrology, Northwestern University, Chicago, IL*

Purpose: We hypothesized racial/ethnic disparities to access the kidney transplant (KT) waitlist (WL) remain after the implementation of the new kidney allocation system (KAS) at a state level.

Methods: We used the US Renal Data System (URSRDS) data from 1/1/2004 - 12/31/2018 for ESRD patients who resided in Illinois at the time of dialysis initiation. Inclusion criteria were; 1) 18 -70 years at dialysis initiation, and 2) first KT only. Multi-organ transplant was excluded. A competing risk analysis was conducted with a sub-distribution hazard model stratified by race/ethnicity. Death on dialysis was considered as a competing risk for waitlisting. Sub-distribution hazard ratio (SHR) between the pre-KAS (11/1/2004 - 12/4/2015) and post-KAS (12/5/2015 - 12/31/2018) compared Black and Hispanics to Whites.

Results: A total of 47,484 patients were included with 39,646 in the pre-KAS and 7,838 patients in the post-KAS era based on initiation date of dialysis. In the pre-KAS group, 10,472 (26.4%) patients were added to the WL. 764 (10.8%) patients enrolled on the WL during the post-KAS era. Before KAS, Black patients had the lowest SHR (0.945, p=0.01) for WL enrollment, with Hispanics (1.331, p<0.001) and others (1.693, p<0.001) above Whites. Post-KAS SHR of WL addition in Blacks fell even lower (0.639, p<0.001), relative to Whites. The SHR dropped somewhat for Hispanics (1.208, p=0.01) and Others (1.551, p<0.001) (Table 1).

Conclusions: In Illinois, the disparity in access to the WL became worse for Blacks in the post-KAS era. Causes for the widening gap need to be explored, to find mitigation solutions.

Table1) Sub-distribution hazard ratio for getting on WL in preKAS and postKAS era by race/ethnicity

PreKAS (Since 2004-12/4/2015)

	SHR	P-value
Black	0.945	0.01
Hispanic	1.331	<0.001
Others	1.693	<0.001

PostKAS (12/5/2015-12/31/2018)

	SHR	P-value
Black	0.639	<0.001
Hispanic	1.208	0.01
Others	1.551	<0.001

Abstract# 698

The Impact of Lack of Access to Simultaneous Kidney and Pancreas Transplantation Due to Insurance Ineligibility - A Single Center Analysis

Y. A. Qazi, E. Villalon, D. Samson, W. Mon, M. Smogorzewski, *Keck Medical Center at USC, Los Angeles, CA*

Purpose: Simultaneous kidney and pancreas transplantation(SPK) provides a survival and quality of life advantage in young, low BMI insulin dependent diabetics with End Stage Renal Disease (IDDMesrd). Because of secondary complications such as retinopathy, many are disabled and unable meet eligibility for Medicare coverage. The greater Los Angeles metropolitan area has had no active pancreas transplant program for Medi-cal patients (CA's Medicaid) with the nearest one contracted in San Francisco. The purpose of our study was to compare the transplant rate and waitlist mortality in diabetics under 50 years of age based on their insurance status.

Methods: IDDMesrd patients referred to our center and medically eligible for SPK were analyzed in this study. Following were the inclusion criteria ; Age < 50 years, Insurance status : Medi- cal or Medi-care. Other form of insurances were not included in this study. The following data was collected: waitlist mortality (both active and active on the list) , transplant rate and type of transplant.

Results: There were 129 patients that met the eligibility criteria- 47 Medi-Cal and 82 MedicareWaitlist mortality for Medi-cal was 10/47 (21%) , 0 patients received a SPK and 5/47 (10%) received a kidney transplant alone. Waitlist mortality for the Medicare group 11/82(13%) ,16/82 (20%) received a SPK.

Conclusions: In our single center analysis of young IDDMesrd ineligible for a SPK due to insurance, the waitlist mortality was almost double and transplant rate half when compared to individuals that were insurance eligible. The higher transplant rate in the Medicare group is likely the result of shorter wait times for SPK compared to kidney alone in the Los Angeles area. Young Medi-Cal IDDMesrd patients in the greater Los Angeles area that are unable to be to be listed for SPK locally due to insurance, are significantly disadvantaged and suffer higher mortality and lower transplant rates. There is an urgent need for Med-ical to provide more local access for SPK in the greater Los Angeles area.

Abstract# 699

Trends of Kidney Transplant Volume During Covid-19 Era

G. Rajashekar[1], S. Chang[1], K. Lentine[2], J. Wellen[1], T. Alhamad[1], M. Merzkani[1], H. Murad[1], *[1]Nephrology, Washington University in St. Louis, Saint louis, MO, [2]Nephrology, SSM Saint Louis University, Saint louis, MO*

Purpose: The emergence of SARS-CoV-2 and the clinical syndrome of COVID-19 have significantly disrupted routine healthcare and life-saving procedures, including solid organ transplantation. This resulted in holding living donor program activity and limiting solid organ transplant at many transplant centers. We examined the trend of kidney transplant volume before and after the first peak of COVID-19 to quantity the impact of the pandemic on kidney transplant practices.

Methods: Data on kidney transplant procedures from the national organ registries, Organ Procurement and Transplantation Network, 1/1/2019-5/31/2020) and Scientific Registry of Transplant Recipients (6/1/2020-9/30/2020) were examined. We excluded multiple organ transplantation.

Results: There were 12,757 deceased donor and 1,889 living donor kidney transplants between Jan 2020 and Sep 2020. The volume plummeted in March, reached a nadir in April, and gradually increased starting from May. There were only 72 living donor kidney transplants performed in April 2020, compared to 530 in the April 2019. However, by September 2020, the volume appeared to return to a level similar to the same month in 2019. In a similar pattern, numbers of kidneys recovered for transplantation decreased in March and April, before recovering in May 2020. **Figure 1**

Conclusions: As testing and PPE supply improve along with more experience with conducting safe transplant procedures during the pandemic, recommendations regarding transplant practice during COVID-19 continue to evolve. The availability of COVID-19 testing with rapid PCR results before transplant has led to an uptake of solid organ transplants and a recovery of suspended practice. Ongoing monitoring of both practices and outcomes is necessary to guide decisions of proceeding with transplantation as the country faces additional surges of COVID-19 during the winter months.

Abstract# 700

Investigating Physician Outlook Regarding Living Donation Prior to Planned Withdrawal of Care

S. Rath[1], L. Washburn[2], S. Creden[1], M. Goss[3], A. Rana[1], J. Goss[1], N. T. Galvan[1], *[1]Baylor College of Medicine, Houston, TX, [2]University of Pittsburgh Medical Center, Pittsburgh, PA, [3]McGovern Medical School, Houston, TX*

Purpose: The aim of this study is to assess the attitudes of physicians, physician assistants, and nurse practitioners in transplant and critical care regarding Living Donation Prior to Planned Withdrawal of Care (LD-PPW), which is the recovery of a living donor organ prior to withdrawal of life sustaining measures in a patient who is not brain dead, but for whom medical care towards meaningful recovery has been deemed futile.

Methods: A case scenario was administered via email through Medical Marketing Services to healthcare practitioners involved in transplant and critical care. This scenario included a survey about a potential LD-PPW donor ("Jason"), and participants rated their agreement with hypothetical statements on a 5-point Likert scale as it pertains to his eligibility to donate (Figure 1). 17519 surveys were distributed, 3611 were viewed, and 148 completed responses were received.

Results: Compared to previously published data surveying public perception of LD-PPW, this pilot data suggests that LD-PPW would be met with similar or even greater support from the professional community, with over 70% of responding practitioners indicating support for LD-PPW (Figure 2). 82% of respondents were confident in their ability to declare futility of care and 94% of respondents felt the care they provide would not vary with a patient's organ donor status (Figure 2).

Conclusions: This study was initiated because donation after cardiac declaration of death (DCDD) does not satisfy the current need for organ donation and transplantation, as nearly half of all DCDD does not proceed to organ donation. LD-PPW has been proposed as an alternative procedure targeted at increasing the quality and quantity of transplantable organs while respecting the donor's right to donate. This pilot study revealed strong support for LD-PPW among healthcare practitioners, reaffirming previously published data of strong support within the public at large. Further research will assist execution of a formalized process for LD-PPW by allaying common concerns and identifying further barriers to implementation.

Figure 1. Case scenario of a potential LD-PPW donor, "Jason", and comprehension questions. At the time of survey distribution, LD-PPW was referred to as Imminent Death Donation (IDD).

Jason has been admitted to the ICU after a serious car accident where the passenger has already died on the scene. He has suffered a devastating brain injury leaving him completely unresponsive but does not fulfill the criteria for brain death. Your team informs his family that although Jason's heart continues to beat, he is unlikely to have any meaningful neurologic recovery and is completely dependent on ventilation. Any other measures would amount to medical futility.

Jason is a registered organ donor. The ICU charge nurse notified the organ procurement organization (OPO) to assess his eligibility to donate. After reviewing his case, the organ procurement organization decides that Jason's organs are healthy but **do not meet the criteria for donation after brain death (DBD)** because he is **not legally brain dead**. He could be eligible for **donation after cardiac death (DCD)** (organ procurement which takes place quickly after removal of life sustaining measures and pronouncement of death). However, approximately 40-45% of DCD donors fail to progress to asystole in the amount of time allotted for successful procurement, and of those organs that are donated, transplant outcomes are not as good as donations from living donors or brain dead donors. Based on DCD tools available, Jason would likely not pass in the 2 hours allotted. Jason's family is disappointed that he cannot donate because they want to honor his wishes and for "something good to come out of this tragedy."

The family then asks if organ donation is possible before withdrawal of life sustaining care. **Like a living donor, Jason could donate one kidney - an organ he could technically live without and would not, in itself, cause death.** After the organ donation procedure, Jason would still have a heartbeat and need a ventilator to breathe. Jason's family would then remove life sustaining care and be present when he passes.

This process would be called **Imminent Death Donation (IDD)**. This donation could **only occur with the consent of Jason's family.**

1. In the above case scenario, was Jason responsive?
2. According to your healthcare team, would Jason recover from his condition?
3. Was Jason able to breathe without the ventilator machine?
4. Was Jason legally brain dead?
5. Could Jason live without one kidney?
6. Could the Imminent Death Donation of organs occur without the consent of Jason's family?

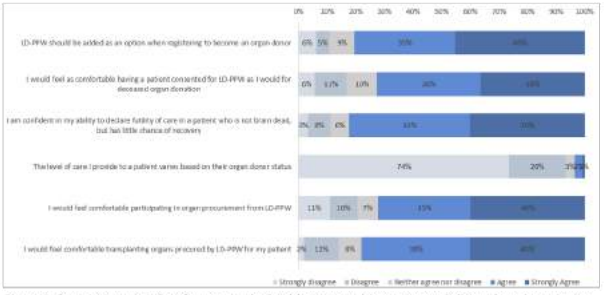

Figure 2. Descriptive statistics of responses by healthcare practitioners towards living donation prior to planned withdrawal of care (LD-PPW), called Imminent Death Donation (IDD) at the time of survey administration. Participants (n = 148) rated their agreement on a 5-point Likert scale with statements about a hypothetical patient and potential living donor prior to planned withdrawal of care, "Jason", in a case scenario.

Abstract# 701

Impact of Traveling for Transplant on Access to and Outcomes from Kidney and Liver Transplantation

K. Ross-Driscoll[1], R. Lynch[1], D. Axelrod[2], R. Patzer[1], *[1]Emory University, Atlanta, GA, [2]University of Iowa, Ames, IA*

Purpose: Newly developed transplant referral regions (TRRs) can be used to understand how and why patients travel outside of their home transplant center to receive care. We used TRRs to estimate the association between travel for transplant and transplant access and outcomes for kidney and liver candidates.
Methods: We obtained data on adult kidney and liver transplant candidates listed from 2006 to 2016 from SRTR. Traveling for transplant was defined using TRRs, and categorized as (1) no travel, (2) travel to a neighboring TRR, (3) travel to an outside TRR, or (4) dually listed in home TRR and outside TRR. We estimated cause-specific hazard ratios for the association between transplant travel, time to transplant, and waitlist mortality, adjusting for clinical and demographic factors. We used Cox proportional hazards models to estimate the association between transplant travel and post-transplant survival.
Results: Between 2006 and 2016, 108,864 kidney and 32,314 liver candidates were listed outside their home TRR. Kidney candidates who traveled had higher transplant rates (Figure 1A). After adjustment, transplant rates were 7% higher for those who traveled to a neighbor, 12% higher for those who traveled to a non-neighbor, and 23.5% higher for dually listed patients compared to non-travelers. Those who traveled to a neighbor had 7% higher waitlist mortality (csHR: 1.07, 95% CI: 1.05, 1.10) than those who did not travel, while dually listed patients had nearly 50% lower waitlist mortality (csHR: 0.55, 95% CI: 0.53, 0.57). However, dually listed patients had higher post-transplant mortality than non-travelers (HR: 1.45, 95% CI: 1.38, 1.52). Among liver candidates, only those who traveled to a non-neighboring TRR had higher transplant rates relative to those who did not travel (Figure 1B, csHR 1.15, 95% CI: 1.13, 1.19). Dually listed candidates had lower waitlist mortality (csHR 0.80, 95% CI: 0.75, 0.85). Those who traveled to a non-neighboring TRR (HR: 1.06, 95% CI: 1.01, 1.12) and dually listed candidates (HR: 1.60, 95% CI: 1.10, 2.33) had higher post-transplant mortality than those who did not travel.
Conclusions: Traveling for transplant was associated with higher rates of transplant and shorter waiting time, but dually listed candidates appeared to have higher post-transplant mortality. Further research is needed to understand how transplant travel affects patients, transplant centers, and the communities they serve.

Figure 1. Cumulative incidence functions for kidney (A) and liver (B) waitlist outcomes, by travel group.

Abstract# 702

Accounting for Survivor Bias in Transplant Benefit Models

E. M. Schnellinger[1], E. Cantu[2], M. O. Harhay[1], D. E. Schaubel[1], S. E. Kimmel[1], A. J. Stephens-Shields[1], *[1]Department of Biostatistics, Epidemiology, and Informatics, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [2]Department of Surgery, Division of Cardiovascular Surgery, Hospital of the University of Pennsylvania, Philadelphia, PA*

Purpose: The lung allocation system in the U.S. prioritizes lung transplant candidates based on estimated pre- and post-transplant survival. However, these models do not account for all waitlist candidates; rather, they only account for those who survive on the waitlist long enough to receive transplant. Transplanted candidates may differ from un-transplanted candidates, resulting in survivor bias and inaccurate predictions.
Methods: We propose a weighted estimation strategy to account for survivor bias in the pre- and post-transplant models used to calculate Lung Allocation Scores (LAS), the current basis for prioritizing lung transplant candidates in the U.S. We then created a modified LAS using these weights, and compared its performance to that of the existing LAS via time-dependent receiver operating characteristic (ROC) curves, calibration curves, and Bland-Altman plots.
Results: Overall, accounting for survivor bias improved discrimination and calibration over the existing LAS, and led to changes in patient prioritization. Individuals who received lower (worse) priority under the modified LAS tended to experience increases in their estimated waitlist urgency, whereas those who received higher (better) priority under the modified LAS tended to experience increases in their estimated transplant benefit.
Conclusions: Our approach to addressing survivor bias is intuitive and can be applied to any organ allocation system that prioritizes patients based on estimated post-transplant survival. This work is especially relevant to current debate about methods to ensure more equitable distribution of organs.

Abstract# 703

Has the Proportional Rise in Deceased Organ Donation Rate Over Last 5 Years Been Optimal? Data-based, Forecasting Model Analysis of UNOS/NHSBT UK Donor Data

H. Sharma[1], A. Sharma[2], *[1]Transplant and Vascular Access Surgery, Royal Liverpool University Hospital, Liverpool, United Kingdom, [2]Data Analytics, Loyola University, Chicago, IL*

Purpose: The increase in deceased donor numbers since last decade has been widely reported. We aim to analyse if the trend in rise of numbers has been optimum as per the forecasting casting model based on historical organ procurement data from UNOS/NHSBT UK from 2005-2014.

Methods: We created a Forecasting model using exponential moving average method for time-series forecasting . We compared the forecasted figures to the actual deceased donor numbers for last 5 years (2015-2019) . We also compared the forecasted versus actual donation rates in the minority population group.

Results: The total actual versus forecasted deceased donation rates in US have kept pace p=0.46. In 2019, the actual donation numbers were in excess of forecasted digits but the actual donation rates in minority population in US have shown a negative trend compared to the forecasted figures p=0.002. In the UK, the actual donation rates were inferior compared to the forecasted numbers p=0.02. The actual organ donation rates were sub optimal in minority population too p=0.007.

Conclusions: The actual total deceased organ donation rates in US exceed the forecast but fall in actual donation from minority population compared to forecasted figures indicates failure of social initiatives. The UK actual total and minority population deceased organ donation trends have fallen behind the forecasted figures. More creative initiatives are needed to involve the minority population to improve the numbers

	Total Deceased Donors USA	Total Deceased Donors USA Forecasted	Minority USA Donors	Minority USA Forecasted	Total Deceased Donors UK	Total Deceased Donors UK Forecasted	Minority UK Donors	Minority UK Forecasted

Abstract# 704

Panic in the Pandemic: A Medical Decision Analysis Examining When Kidney Transplant Programs Should Close

A. J. Vinson[1], B. Kiberd[2], K. Tennankore[1], *[1]Nova Scotia Health Authority Division of Nephrology, Departm, Halifax, NS, Canada, [2]Dalhousie University, Halifax, NS, Canada*

Purpose: Pandemics greatly interfere with overall health care delivery as resources are diverted to combat the crisis. Kidney transplantation programs were closed temporarily during the COVID-19 pandemic. Given the critical shortage of organs and the overall importance of transplantation in improving length and quality of life for those with kidney disease, this analysis examines the impact of discarding deceased donor organs or in the case of live donation, deferral during a pandemic.

Methods: The net benefit (or harm) of discarding deceased donor organs or deferring live donor kidney transplant was measured in projected life years from a societal and individual perspective using a Markov model. A wide range of infection rates, pandemic durations, and case fatality rates associated with infection in waitlisted and transplant recipients was examined.

Results: Overall, patient life expectancy fell for both waitlisted and transplant recipients as the pandemic conditions became more unfavourable. However, the overall net benefit of a transplant during the pandemic was preserved. Even assuming plausible but higher relative case fatality rates in transplant recipients compared to waitlisted patients and risks of nosocomial and donor transmission, there remained a benefit with proceeding with deceased donor kidney transplant; net benefit >4 years up until age 60, Table 1. The net benefit of proceeding with live donor transplant during a pandemic was >7 years for all ages. Deferring transplantation, even accounting for additional pandemic-associated risk, negatively impacted most recipients.

Conclusions: As long as hospitals have adequate resources to deal with the pandemic and can limit nosocomial infection, kidney transplantation should not be curtailed.

Table 1. Life Years by Options: Baseline Variables

Age	Transplant COVID-19	Transplant No COVID-19	Wait List (WL) COVID-19	Wait List No COVID-19	Difference COVID-19 (Transplant-WL) No COVID-19 (Transplant-WL) Transplant (No COVID-COVID)

Abstract# 705

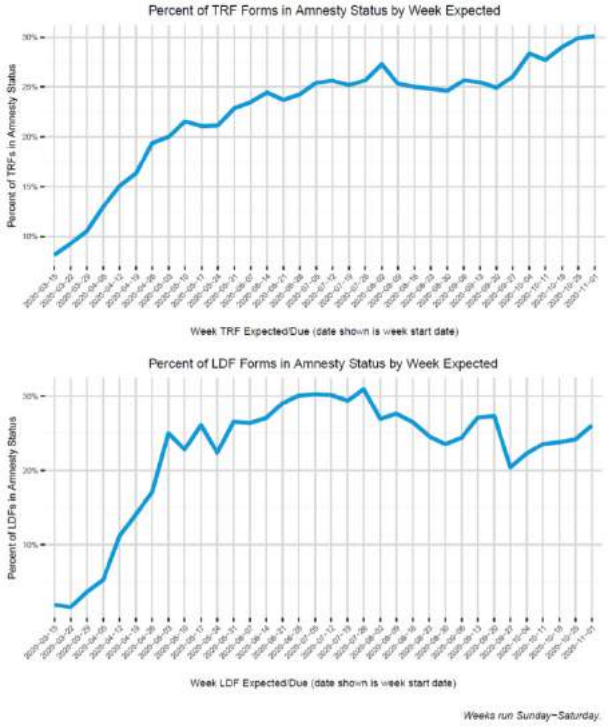
Summary of the OPTN's Policy and System Modifications in Response to the COVID-19 Pandemic

A. Wilk, S. Taranto, C. Jett, L. Cartwright, *UNOS, Richmond, VA*

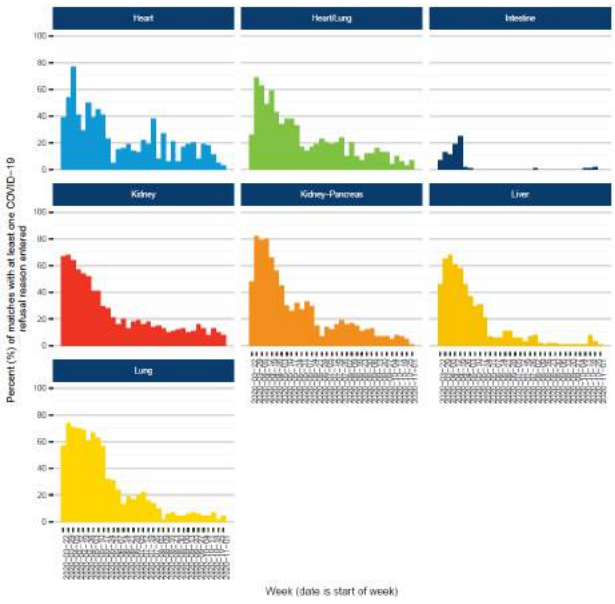
Purpose: In April 2020, the OPTN made several policy and system modifications in response to the growing COVID-19 pandemic including updates to candidate lab data, relaxing data submission requirements, incorporation of donor COVID-19 infectious disease testing, and the addition of new COVID-19 specific offer refusal and candidate cause of death codes. The changes were intended to reduce institutional burden in a time of unprecedented challenge to the US healthcare system and to protect transplant candidates/recipients from unnecessary potential COVID-19 exposure.

Methods: OPTN candidate, donor, and recipient data was analyzed by week from March-November 8, 2020.

Results: The percent of candidates that appeared to carry labs forward to maintain waiting list status has been low and varied by organ and candidate age group (0-17% in any given week). The number and percent of TRF and LDF forms in amnesty status at form due date has grown since policy implementation, remaining at ~25-30%, and varied by OPTN Region and organ.



There continues to be a decline in the percent of matches with at least one COVID-19 refusal reason for all organs from a peak of over 60% in March to <20% in November.



The proportion of COVID-19 related waiting list deaths among all reported deaths was highest for kidney, and decreased from a high of 26% in mid-April to an average of 6% per week in October. All OPOs that recovered deceased donors reported COVID-19 donor testing results through the optional donor infectious disease fields in DonorNet or via free response donor text fields or attachments. At the time of this analysis, no donors with a known active COVID-19 infection were transplanted.

Conclusions: As the COVID-19 pandemic continues to evolve, the OPTN Executive Committee has been committed to monitoring the usage and impact of these modifications and is weighing committee feedback and public comment responses in determining a path forward. There was broad support from the community during public comment to maintain these changes until the healthcare system is able to resume normal operations despite concerns regarding missing data from follow-up forms in amnesty status. There continues to be remarkable transplant community involvement in responding to the evolving challenges faced by the nation's healthcare system.

Abstract# LB 71

The Calculated Panel of Incompatible Epitopes (cPIE) in the Service of Equitable Access to Transplantation

J. Lamsatfi[1], B. Bingfan Liu[1], S. Parto[2], A. Lewin[3], K. Oualkacha[1], F. Claas[4], P. Keown[5], R. Sapir-Pichhadze[6], *[1]McGill University, Montreal, QC, Canada, [2]McGill University Health Centre, Montreal, QC, Canada, [3]Hema-Quebec, Montreal, QC, Canada, [4]Leiden University Medical Centre, Albinusdreef, Netherlands, [5]University of British Columbia, Vancouver, BC, Canada, [6]Medicine, McGill University Health Centre, Montreal, QC, Canada*

Purpose: To inform on feasibility of eplet matching, we developed the calculated Panel of Incompatible Epitopes (cPIE), an algorithm informing on the likelihood of identifying blood group and eplet-compatible donors. We applied cPIE to study how self-identified ethnicity may affect access to transplantation.

Methods: Analyses were conducted in a subcohort of 1568 participants from the Hema-Quebec Stem Cell Registry (HQ) who underwent genotyping for 11 HLA loci by NGS (Jan 2018-Jan 2020). Genotypes were transformed to epitypes and blood groups were assigned randomly using distributions in self-reported ethnic groups of Quebec blood donors. Participants from the HQ subcohort with similar self-reported ethnicity represented candidate groups. The likelihood of finding blood group matched and eplet compatible donors was assessed by the cPIE algorithm considering eplet compatibility thresholds limited to antibody-verified (AbVer), HLA class II, and a subset of 15 eplet mismatches highly predictive of death-censored graft failure. For each threshold, donors from the entire HQ subcohort were deemed compatible, if all their eplets were included in the candidates' epitypes. Distributions of cPIE were also assessed when considering blood group compatible donors.

Results: The distribution of cPIE (Median and Interquartile Range (IQR)) by 16 self-identified ethnic groups represented in HQ (Arab (N=25), South Asian (N=9), South East Asian (N=5), Black African (N=9), Black American (N=15), Black Other (N=6), Caucasian (N=966), Chinese (N=13), Philippine (N=7), First Nation (N=8),

SMALL BOWEL

Hispanic (N=126), Jewish Ashkenazi (N=82), Jewish Sephardi (N=42), Metis (N=5), Other (N=240), and Unknown (N=10)) for each eplet compatibility threshold are presented in Table 1. Likelihood of finding donors was greater when allowing blood group compatibility with candidates.

Conclusions: Across self-identified ethnicities there is extensive heterogeneity at the individual level in the likelihood of identifying blood group and eplet-compatible donors. Verification of individual candidates' allele-level HLA genotypes is needed to inform on access to transplantation. For harder to match candidates, blood group compatibility may help expand the donor pool.

Intestinal Transplantation and Rehabilitation

Abstract# 1245

Dynamic Reconstitution of Recipient Resident Memory T Cell Repertoire After Human Intestinal Transplantation

W. Jiao, M. Martinez, J. Zuber, A. Obradovic, R. Jones, E. Waffarn, Z. Wang, A. Gorur, K. Rogers, T. Kato, Y. Shen, J. Fu, M. Sykes, *Columbia University, New York, NY*

Purpose: Our studies in intestinal transplant (ITx) recipients demonstrated that donor T cell blood macrochimerism(peak level ≥4%) is associated with slower graft T cell replacement by the recipient and less rejection. Graft-infiltrating recipient T cells gradually take on the resident memory (TRM) phenotype during quiescence. However, TRM repertoire formation under quiescent and rejection conditions is largely unexplored.

Methods: We have investigated the dynamics of T cell receptor (TCR) repertoire reconstitution by recipient T cells in intestinal allografts across time and space by applying TCR sequencing and flow cytometry from pre-Tx recipient lymphoid tissue and post-Tx gut and blood over years.

Results: In ileal allografts, cumulative percentages of TCRs identified in earlier graft biopsies increased over time, demonstrating the establishment of a stable recipient repertoire (Fig. 1). Establishment of a stable repertoire appeared more rapid in patients without blood macrochimerism, as 4 out 4 showed an overall decline in jensen-shannon divergence (JSD) values between adjacent times in ileum within 400 days. In contrast, 5 out 6 patients with blood macrochimerism and long-term follow up showed delayed establishment of a stable repertoire, as reflected by either an increased or a stable trend of JSD values. Low JSD values in Pts 15 and 13 early post-Tx reflected persistent donor TRM repertoires and JSDs increased as recipient cells eventually replaced those of the donor. The delay in recipient replacement of donor TRM resulted in a delay in the establishment of a stable recipient repertoire. Recipient sequences were shared across different gut tissues and these demonstrated higher clonal dominance and lower diversity compared to those appearing in only one gut region, indicating that dominant recipient-derived TRM T cell clones seeded the entire gut, including the native colon (Fig. 2).

Conclusions: Our data reveal the dynamic establishment of a stable TRM repertoire over time after ITx by recipient T cells across different regions of the gut. This process is more rapid in patients without blood macrochimerism, who are also more prone to rejection.

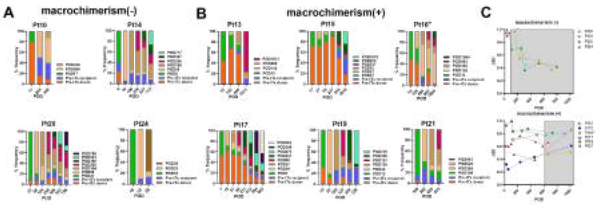

Figure 1. Graft-infiltrating recipient T cells gradually established a stable repertoire after ITx. (A) and (B) Dynamic establishment of the recipient TCR repertoire in intestinal allograft in patients without ("-") and with ("+") macrochimerism. In bar plots, the top 1000 sequences defined by frequency in each ileal sample collected on different post-operative days (POD) are presented and their constitution from pre-Tx donor or recipient mappable clones and clones first identified in the indicated PODs are shown. "Putative de novo sequences" are defined as sequences first identified at the designated time point but not previous time points and are located on the top section of each bar. (C) Dynamic establishment of the recipient repertoire in patients with ("+") and without ("-") macrochimerism is shown. Repertoire stability was reflected by changes of JSD values between adjacent time points among the top 1000 sequences identified at each time point post-Tx. JSD values range between 0 and 1, where 0 indicates identical repertoires and 1 indicates complete divergence. Grey shaded areas indicate the overall time frame when >50% of donor T cells in an ileum allograft had been replaced by the recipient.

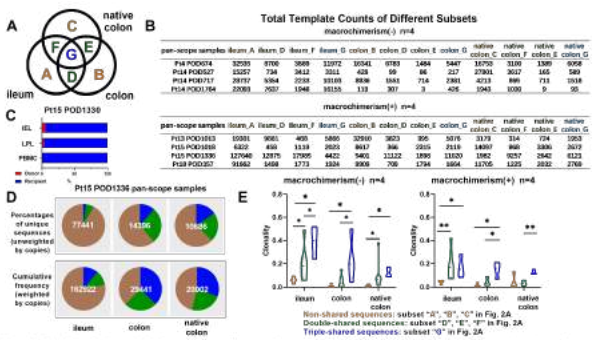

Figure 2. Clonal distribution and dominance across different regions of the gut late post-Tx. (A) Venn diagrams illustrate the subsets of sequences ("A" to "G") appearing in different regions of the intestine in one patient at a given time point when transplanted ileum, transplanted colon and native colon were simultaneously biopsied through a pan endoscopic procedure. (B) Total template counts of different subsets for each pan-scope sample are shown. Non-shared sequences (in subset "A", "B", "C") are in brown. Double-shared sequences (in subset "D", "E", "F") are in green. Triple-shared sequences (in subset "G") are in blue. Samples were included if recipient T cell chimerism in gut >90% and total template counts >500. (C) Chimerism status in PBMC, ileal intraepithelial lymphocytes (IEL) and lamina propria lymphocytes (LPL) in Pt15 POD1330 is shown, one week earlier than the pan-scope performed on POD1336. (D) Representative pan-scope samples collected from Pt15 on POD1336 showed higher fractions for those sequences shared across 3 different gut tissues when measured by cumulative frequency compared to unique sequence numbers. Pie chart color codes match each subset defined in Fig. 2A, 2B and 2E. Total number of unique sequences or templates within samples are shown in the center of each pie. (E) Triple-shared sequences had higher clonalities compared to double-shared sequences or non-shared sequences, regardless of the status of blood macrochimerism. Mann-Whitney test was performed to determine statistical significance: * p<0.05, **p<0.01.

COVID-19

COVID-19

Abstract# LB 43

SARS-CoV-2 Infection in Solid Organ Transplant Recipients: A Retrospective Cohort Study

A. Adeel, *Infectious Diseases, University of Massachusetts, Worcester, MA*

Purpose: Initial studies of COVID-19 in solid organ transplant (SOT) recipients demonstrated high mortality rates, but more recent comparative data shows contradictory results.

Methods: We evaluated differences in demographic characteristics, comorbidities, clinical presentation, and outcomes among three patient groups based on their solid organ transplant status and COVID-19 status between 3/1/2020 and 6/30/2020: SOT recipients with COVID-19 (T+|C+), SOT recipients who tested negative for COVID-19 (T+|C-), patients with cirrhosis or end-stage renal disease (ESRD) who were positive for COVID-19 (T-|C+). Controls (T-|C+) were chosen in a 2:1 match with cases (T+|C+) based on age range, gender and testing date. Bivariate analyses were done using chi-square and Fisher's exact test for categorical data and ANOVA for continuous data using STATA 15. Bonferroni correction was applied for multiple comparison.

Results: A total of 222 patients were included in this analysis, 22 (10%) T+|C+, 153 (69%) T+|C-, 47 (21%) T-|C+ (Table 1). Among transplant recipients, patients with COVID-19 were more likely non-Hispanic Black or Hispanic and younger. T+|C+ patients were more likely to present with symptoms than other groups; however, they were less likely to be hospitalized and die ($p < 0.01$). Among patients with COVID-19, patients with transplant were less likely to require supplemental oxygen support ($p = 0.01$) and ICU admission ($p = 0.05$). SARS-CoV-2 PCR cycle thresholds are shown in Figure 1.

Table 1: Characteristics, comorbidities and presenting symptoms of transplant patients with and without COVID-19 and non-transplant patients with COVID-19

	Transplant COVID + T+ | C+ (N=22)	Transplant COVID - T+ | C- (N=153)	Controls COVID - T- | C+ (N=47)	P-value

Abstract# LB 44

Kidney Transplantation in Patients with Prior Coronavirus Disease 2019 (COVID-19)

A. Santeusanio, A. Bhansali, M. Rana, S. Lerner, D. Von Ahrens, O. Sulimani, S. Farouk, F. Tedla, R. Shapiro, *Mount Sinai Hospital, New York, NY*

Purpose: We describe short-term outcomes as well as peri- and post-transplant complications in patients with prior coronavirus disease 2019 (COVID-19) who subsequently underwent kidney transplantation.
Methods: This was a single-center, retrospective cohort study of all recipients of isolated living- or deceased-donor kidney transplants between 4/1/2020-10/1/2020. Patients with prior PCR confirmed COVID-19 were considered candidates for kidney transplantation if they were at least 4 weeks post-infection, had resolution of symptoms, and had one negative nasopharyngeal PCR swab specimen. Standard doses of induction and maintenance immunosuppression were administered at the time of transplant and included anti-thymocyte globulin, tacrolimus, mycophenolate, and tapering corticosteroids. Patients were followed from the date of transplantation until study conclusion (11/1/2020), to compare short-term patient and allograft outcomes between those with prior COVID-19 and COVID-19 naïve controls transplanted during the same time-period.
Results: 81 patients received isolated kidney transplants during the review period, 13 (16.0%) of whom had recovered from prior COVID-19 infection. The median time between COVID-19 diagnosis and transplantation was 71 (IQR=56.5-135) days, and all 10 patients who were tested had evidence of significant antibody titers to the SARS-CoV-2 spike protein. The majority of patients had mild disease (69.2%), while 3 patients required hospital admission and supplemental oxygen, and 1 patient required mechanical ventilation. Baseline characteristics were similar between COVID-19 positive and negative patients, with the exception of more Hispanic/Latino patients in the prior COVID-19 group (53.8% vs 17.6%; p<0.01). At study conclusion, after a median follow-up of 3.6 months, patient and allograft survival were similar between COVID-19 positive and negative patients (92.3%/92.3% vs 100.0%/98.5%), and mean baseline serum creatinine was 1.5 mg/dL in both groups. One patient with prior mild COVID-19 died due to a pulmonary embolism within 1-month of transplant; however, no differences were observed in the overall rate of thromboembolism (7.7% vs 4.4%; p=0.61). Index hospital length of stay and readmission rate within 30-days of transplant were also similar between groups, but patients with prior COVID-19 did have a higher incidence of delayed extubation post-transplant (15.4% vs 1.5%; p=0.02). No cases of COVID-19 re-infection or biopsy proven allograft rejection were observed among patients with prior COVID-19.
Conclusions: In our preliminary experience, patients with prior COVID-19 infection appeared to have similar short-term outcomes when compared with COVID-19 naive patients. We did observe a potential signal for increased peri-operative respiratory complications in patients with prior COVID-19, which may warrant additional monitoring and further study in multi-center cohorts.

Abstract# LB 45

Kidney Transplant Biopsy Findings After Covid-19

E. Daniel[1], S. Kudose[2], D. J. Cohen[1], L. Ratner[3], V. D'Agati[2], I. Batal[2], *[1]Division of Nephrology, Columbia University Medical Center, NY, NY, [2]Department of Pathology, Columbia University Medical Center, NY, NY, [3]Department of Surgery, Columbia University Medical Center, NY, NY*

Purpose: COVID-19 has been reported as a cause of kidney injury and data from published native kidney biopsy results demonstrate a variety of causes. To our knowledge, there are no published series looking specifically at kidney allograft biopsy findings in patients with COVID-19.
Methods: We identified 10 kidney transplant recipients who underwent allograft biopsy within one month after infection with SARS-CoV-2 virus. We collected data regarding patients' clinical characteristics, transplant history, COVID-19 illness, and histology and immunohistochemistry findings of the kidney allograft biopsies.
Results: Patients had a median age of 50.3 years, and four of the patients were female. Demographics included four Hispanics, three Whites, two Blacks, and one unidentified. All patients had co-morbidities, including hypertension in eight and diabetes in three. Cause of allograft biopsy was acute kidney injury (n=9), proteinuria (n=2), and nephrectomy after allograft failure (n=1). 6/10 had developed COVID pneumonia, and two of those required mechanical ventilation.On analysis of histology results, three had severe acute rejection (two with acute T cell rejection - grades 2A and 2B, and one with a mixed rejection), two revealed podocytopathy (one with collapsing

glomerulopathy and one with recurrent lupus podocytopathy), one showed cortical necrosis, one had chronic thrombotic microangiopathy/transplant glomerulopathy, one had acute tubular injury, and two showed no specific histologic abnormalities. Immunohistochemical staining for SARS-N-Capsid was negative in 5/5 biopsies where performed.Follow up data including serum creatinine levels was available for 8/10 patients. Of these, only two demonstrated an improvement in kidney function back to baseline. No deaths were reported in the studied population.

Conclusions: This series of kidney transplant recipients who underwent allograft biopsy after COVID-19 illness demonstrates a wide variety of causes of kidney allograft dysfunction, the most common of which was rejection. Similar to the cases of native kidney dysfunction, we found no evidence of direct viral invasion.

Liver and Kidney Transplantation During the Covid-19 Pandemic Period: A Single Center Experience

M. Haberal[1], E. Karakaya[1], A. Akdur[1], E. Ayvazoglu Soy[1], F. Ozcay[2], E. Baskin[3], S. Boyacioglu[4], A. Torgay[5], S. Yildirim[1], G. Moray[1], F. Yarbug Karakayali[1], *[1]Division of Transplantation, Department of General Surgery, Baskent University, Ankara, Turkey, [2]Department of Pediatric Gastroenterology, Baskent University, Ankara, Turkey, [3]Department of Pediatric Nephrology, Baskent University, Ankara, Turkey, [4]Department of Gastroenterology, Baskent University, Ankara, Turkey, [5]Department of Anaesthesiology, Baskent University, Ankara, Turkey*

Purpose: Introduction: Beginning of this year, when the Covid-19 pandemic has first started, it had the immediate effect of severely reducing living and deceased organ donation and transplantation activity worldwide. Our early experience showed that neither hemodialysis nor transplant patients have got infected with Covid-19 higher than the normal population. While it seems obvious that life-saving transplant activity should not be stopped, it should be tailored with careful selection of both donors and recipients within **transparency** and considering **ethical and legal aspects.**

Methods: Materials and Methods: With the declaration of COVID-19 as a pandemic, many studies have indicated that elective surgeries including transplantation should be postponed. However, according to our study results, we decided to continue our transplant activities in a controlled manner at our centers located in 3 different cities. From March 1 2020 to December 30, 2020, we performed 69 kidney transplants (58 adults, 11 pediatrics) and 21 liver transplants (8 adults, 13 pediatrics). All recipients were given a routine immunosuppressive protocol. We reviewed the medical records of both recipients and donors, PCR tests have been carried out twice before transplantation, and they were screened with thoracic CT.

Results: Results: Kidney transplants were performed from 67 living related and 2 deceased donors and liver transplants were performed from 20 living related and 1 deceased donors. Out of 69 kidney transplants, 68 patients are alive with normal kidney function and 1 patient died to due to cardiac problem. Out of 21 liver transplants, 20 patients are alive with normal liver function and 1 patient died due to cardiac oxalosis. During this period, no patients died due to Covid-19 pandemic, both recipients and donors were discharged successfully. Only one patient has got infected with Covid-19 and has recovered.

Conclusions: Conclusions: Our results show that when precautions are taken, transplant does not pose a risk to patients during the pandemic period. The safety and success of our transplantation activities lies in our newly developed protocol in response to the COVID-19 pandemic.

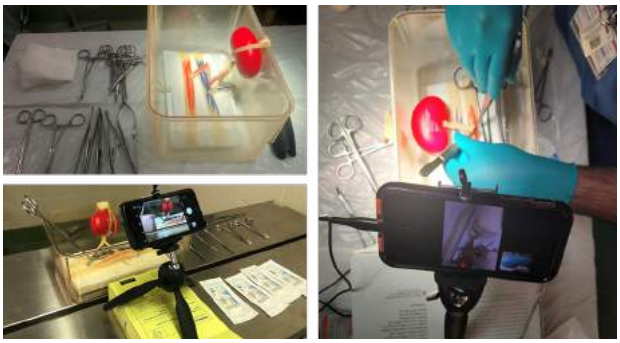
Abstract# LB 47

Feasibility of a Virtual Renal Transplant Simulation Model for Surgical Trainees in the Covid Era

O. Eletta[1], S. Iacono[1], D. Walls[1], S. Puri[2], B. Perry[1], C. Anderson[1], M. J. Nguyen[3], A. Bongu[2], *[1]General Surgery, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [2]Transplant, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [3]Transplant Institute, Loma Linda University Medical Center, Loma Linda, CA*

Purpose: The COVID-19 pandemic and social distancing requirements has affected our resident education curriculum. We developed a virtual renal transplant simulation session to simulate renal vascular anastomoses (RVA). We hypothesize that this tool can be used to continue surgical skills education and enhance resident comfort with RVA in the COVID era.

Methods: We employed a well described model to mimic RVA to the iliac vessels using a mock kidney and penrose drains in a 5x8x11inch transparent container to simulate operating in the iliac fossa. Additionally, each kit included camera stands for mobile phones. General surgery residents with varying levels of experience participated. Our virtual workshop started with a demonstration and took place via a live video interface from several remote locations. An attending surgeon observed each resident and provided real time feedback. Pre and post simulation surveys were sent out to elicit comfort levels with procedure on a scale from 0 (not comfortable) to 100(very comfortable) and fidelity as a tool to improve general surgery residency training in renal transplantation.



Results: 16 surgical residents participated in the simulation. 12 (75%) had previously rotated on transplant surgery service. 75% of residents reported performing <10 vascular anastomoses. There was a statistically significant increase in mean comfort level score with performing a vascular anastomosis after the simulation compared to before (52 vs 23, P <0.01). There was also a statistically significant increase in mean comfort level score for assisting with a vascular anastomosis after compared to before (70 vs 38, p<0.01). 100% of residents reported that the model was useful for practicing needle control and precision, practicing knot tying, and learning the steps for completing renal vascular anastomoses. All residents recommended that this training model be used prior to rotating on the transplant service.

Conclusions: We demonstrated the feasibility of virtual sessions that surgical residents found to be effective in improving their technical skills. This method can be modified for other elements of surgical simulation while maintaining social distancing measures.

Abstract# LB 48

Living Organ Donor Perspectives on Covid-19 Vaccines

M. N. Harhay[1], A. Klassen[2], H. Zaidi[1], M. Mittelman[3], R. Bertha[3], R. Mannon[4], K. Lentine[5], *[1]Medicine, Drexel University, Philadelphia, PA, [2]Drexel University, Philadelphia, PA, [3]American Living Organ Donor Fund, Philadelphia, PA, [4]University of Nebraska Medical Center, Omaha, NE, [5]Saint Louis University, Saint Louis, MO*

Purpose: Promoting widespread COVID-19 vaccinations is a crucial strategy to protect living organ donors and transplant recipients during the pandemic. We examined perspectives and sources of hesitancy about COVID-19 vaccines among former and prospective living organ donors.

Methods: We conducted an IRB-approved study of US living organ donors and prospective donors. An online survey was disseminated on multiple social media platforms between 12/28/20-2/9/21. Survey items included multiple choice, ranking, and ratings of agreement to statements about COVID-19 vaccine effectiveness, convenience, and importance. We used descriptive statistics and a multivariable logistic regression model to examine associations between respondent characteristics and preferences and COVID-19 vaccine acceptance.

Results: Among 323 respondents from 40 US states and DC, 53% were 31-50 years old, 91% were non-Hispanic white, and 88% were female. Respondents included 267 living donors (94% kidney) and 56 in evaluation to donate (75% kidney). When asked if they would accept a COVID-19 vaccine, 76% answered yes, 11% no, and 13% unsure. Compared to those who would decline a vaccine or are unsure, respondents who would accept a vaccine were more likely to receive yearly influenza vaccines (48% vs 83%, p<0.001) and rely on public health officials for information (4% vs 35%, p<0.001). Respondents who relied on information sources other than public health officials were less likely to agree that COVID-19 vaccines are safe, effective, adequately studied or that donors and recipients should receive COVID-19 vaccines (**Figure**). Adjusting for demographics, education, and donor type, prioritization of public health officials for information and acceptance of yearly influenza vaccines were independently associated with higher COVID-19 vaccine acceptance (p<0.001 for both). The association between public health official guidance and higher

COVID-19 acceptance was similar among respondents who do and do not receive yearly influenza vaccines (adjusted marginal probabilities of vaccine acceptance of 97% and 94%, respectively).
Conclusions: Living organ donors who prioritize information from public health officials are more likely to accept a COVID-19 vaccine than those who rely on other information sources. Transplant programs could incorporate public health messaging and education when discussing the risks and benefits of COVID-19 vaccination.

Abstract# LB 49

Sars-cov-2 Stat Testing for Organ Donation; One Laboratory's Experience

S. Dionne, B. O'Neale, *VRL-Eurofins, Centennial, CO*
Purpose: The COVID-19 pandemic took the U.S. by storm. The Transplant Community had to navigate through unprecedented scenarios in order to continue the life-saving mission of donation. Testing for SARS-CoV-2 initially was not readily available to all OPOs. This abstract reviews the early data of STAT testing for a single OPO in Region 8.
Methods: Retrospective data analysis was performed spanning a seven-month time period (July 2020-Jan 2021). SARS-CoV-2 testing was performed using Transcription Mediated Amplification on the Panther platform. 148 donors were evaluated.
Results: We needed to factor the feasibility of adding an additional STAT test to the lab work assignments. When choosing an assay/instrumentation, outside of sensitivity and specificity, we took into consideration the ability to streamline testing in our lab operations. The results of 148 deceased donor SARS-CoV-2 results were retrospectively reviewed. TAT averaged 6.4 hours for testing; there was no negative impact to the standard infectious disease panel TAT. TAT was efficient for two reasons (i) Lab Management assessed staffing needs and made adjustments to accommodate the additional STAT test (ii) the Panther allows for random access for STAT sample loading/testing. AST recommendations are that donors should be screened epidemiologically and a clinical history for suspected infection should be performed. The prevalence for asymptomatic disease is high. Our SARS-CoV-2 reactive rate for deceased donors averaged 5.8%. We observed trends in the reactive rates which mirrored the restrictions and relaxed restrictions that were imposed by the State. The rates increased during the holiday season when COVID-19 was prevalent in our DSA.
Conclusions: While the risk of transmitting SARS-CoV-2 through organ transplantation is not known, this data demonstrates the importance of continued screening for donors to prevent the potential for donor-derived recipient infection. With proper laboratory planning and choosing an assay/platform that can be streamlined into operations, STAT testing options for new diseases is achievable without majorly delaying organ allocation practices.

Abstract# LB 50

Covid-19 Severity within One Year of Liver, Pancreas and Kidney Transplantation

H. Sarumi, J. Fisher, B. Johnson, T. Pruett, *Solid Organ Transplant Surgery, University of Minnesota, Minneapolis, MN*
Purpose: The current pandemic has created uncertainty in the severity of COVID-19 in transplant recipients, especially those given lymphocyte depleting therapy within a year prior to acquisition. Our experience was reviewed to stratify outcomes of COVID-19 infection occurring before or after one year from transplant.
Methods: All COVID-19 PCR positive liver, pancreas and/or kidney transplant recipients with a minimum of 28 days follow up were reviewed for demographics and outcomes.
Results: 216 recipients were identified: 20 <1 year and 196 >1 year post-transplant. Almost 80% were kidney alone or with pancreas or liver, ~ 2% pancreas alone and ~19% liver recipients. In the <1 year group 17 (85%) received thymoglobulin induction, 1 (5%) received thymoglobulin rejection treatment 8 days post-transplant and 3 (15%) received steroid rejection treatment 2, 2.5 and 10 months prior to COVID-19 diagnosis. Of recipients > 1 year from transplant there was 1 (0.5%) rejection treated with steroids 8 months prior to diagnosis. In the <1 year group 15% were asymptomatic at time of diagnosis. Both groups had a similar mortality rate. Infections diagnosed >1 year after transplantation had a higher hospitalization rate due to COVID-19, statistical significance was not feasible due to small sample size. There were patients in both groups hospitalized for other reasons. Of those hospitalized for COVID-19, 1 (20%) in the <1 year group was readmitted. This patient was diagnosed with COVID-19 due to fever and dyspnea 2 weeks following SPK, induction included thymoglobulin 2 mg/kg. Immunosuppression was decreased, patient was treated with dexamethasone and remdesivir, but ultimately was intubated and died 29 days following diagnosis. In the <1 year group an additional 4 patients were hospitalized, none of whom required intubation. It is likely that not all COVID-19 positive recipients were captured in this data for the >1 year post transplant group due to loss of follow up.
Conclusions: With a limited experience, COVID-19 infection within the first year after transplantation does not appear to have a greater mortality or hospitalization rate after lymphocyte depletion induction contrasted to recipients acquiring COVID-19 greater than a year after transplantation.

Figure 1: Demographics		
	<1 Year	>1 Year
Age	51.2 (25-73)	54.6 (14-85)
Sex: Male	55.0%	63.3%
Race: Caucasian	50.0%	70.4%
BMI	27 (20.2-33.3)	29.1 (15.5-46.3)
Previous transplant	15.0%	19.4%

Figure 2: Outcomes		
	<1 Year	>1 Year
Symptomatic at Diagnosis	85.0%	80.6%
COVID-19 Hospitalization	25.0%	36.2%
COVID-19 Mortality	5.0%	7.1%
Hospital Readmission	20% (1/5)	13% (9/69)

Abstract# LB 51

Short Term Outcomes in Previously Covid Positive Kidney Transplant Recipients in Pre-vaccine Era

R. Prashar, N. J. Khoury, M. Ramesh, A. K. Patel, *Henry Ford Transplant Institute, Detroit, MI*

Purpose: To study clinical characteristics and short-term outcomes in kidney transplant recipients who were previously infected with SARS-CoV-2

Methods: In this retrospective, single-center case-series, we identified 5 consecutive kidney transplant recipients (KTRs), who were diagnosed with COVID-19 prior to transplant. Data from electronic medical records were retrieved for demographic, epidemiologic and clinical characteristics. All patients were transplanted after meeting institutional requirements of resolution of COVID-19 infection. Patients were required to have a negative Nasopharyngeal testing by NAT for SARS-CoV-2, 28 days post symptom resolution. For living donor KTRs repeat testing was done at 48 hours prior to transplant date. For deceased donor KTRs, Rapid Nasopharyngeal testing by NAT for SARS-CoV-2 was done at the time of organ offer. Severity of disease was determined by WHO COVID-19 severity classification.

Results: The demographics, severity of COVID-19 disease, timing of transplant and post-transplant course of the 5 KTRs with recovered COVID-19 are shown in .

Patient No	Age at transplant (years)	Gender	Race	Severity of COVID	Days post COVID diagnosis, when patient received transplant	Type of transplant LDKT-Living Donor DDKT-Deceased Donor	cPRA (%)	Induction	Post-transplant SARS-CoV-2 PCR positive	Most recent creatinine (mg/dL) (days post-transplant)
#1	30	Female	White	Mild	78	LDKT	0	Basiliximab	Yes (asymptomatic)	0.95 (166 days)
#2	48	Male	Black	Moderate	192	DDKT	0	ATG	No	1.9 (121 days)
#3	56	Female	Middle Eastern	Moderate	89	LDKT	0	Steroids	No	0.7 (66 days)
#4	28	Female	Black	Mild	255	DDKT	20	ATG	No	1.3 (44 days)
#5	38	Male	White	Moderate	273	LDKT	0	Basiliximab	No	1.3 (41 days)

Three patients received living donor kidney transplant. Patients were transplanted at a median of 192 days after COVID-19 diagnosis, after complete recovery and documentation of 2 negative SARS-CoV-2 PCRs. Three patients had moderate disease requiring hospitalization. Two patients received ATG for induction, 2 received basiliximab and one living related transplant recipient received steroids for induction. Post-transplant course was uncomplicated, except in one patient (#1), who had bleeding and had to be taken back to surgery on post-operative day 4. SARS-CoV-2 PCR was checked as a part of Per protocol with a positive result. However, patient remained asymptomatic, and tested negative 3 weeks posttransplant. The other four patients developed no symptoms of COVID 19 in their post-transplant course and continue to have excellent graft function at a median of 66 days post-transplant.

Conclusions: Potential KTRs with previously resolved COVID 19 disease can be safely transplanted and have favorable short-term post-transplant outcomes. While there could be persistent shedding, re-infection or re-activation of disease, disease course appears to be mild

Abstract# LB 52

Kidney Transplantation in Times of Covid-19 - Decision Analysis in the Canadian Context

I. Yanev[1], M. Gagnon[1], M. Cheng[2], S. Paraskevas[2], D. Kumar[3], A. Dragomir[4], R. Sapir-Pichhadze[4], *[1]McGill University, Montreal, QC, Canada, [2]McGill University Health Centre, Montreal, QC, Canada, [3]University Health Network, Toronto, ON, Canada, [4]Research Institute of McGill University Health Centre, Montreal, QC, Canada*

Purpose: The coronavirus disease 2019 (COVID-19) pandemic significantly impacted the field of transplantation across Canada. In this study, we outline the implications of COVID-19 related interruptions in kidney transplant activities to Canadian end-stage renal disease (ESRD) patients.

Methods: We used an adapted Markov microsimulation model with a 10-year horizon and an ESRD patient perspective to study the effectiveness (patient survival in months) of living (LD) or deceased donor (DD) transplantation vs. halting transplantation for the course of the pandemic. We conducted base case, scenario, and sensitivity analyses to illustrate the impact of patient and donor characteristics as well as SARS-CoV-2 infection rates and pandemic length on the preferred strategy.

Results: The base case analysis suggested that LD offered greater effectiveness (99.18 months, 95% CI 98.32-100.04) in comparison to delaying LD and remaining on dialysis for the duration of the pandemic (95.7 months (95% CI 94.80-96.6)). In contrast, DD offered effectiveness of 95.4 months (95% CI 94.50-96.30) in comparison to 94.3 months (95% CI 93.38-95.22) when experiencing interruptions in DD transplant activities for the duration of the pandemic. Infection incidence greater than 1.4% over 5-months, shorter periods of interruptions in transplant activities, younger candidates, delayed pre-emptive transplants and transplantation of donors with higher Kidney Donor Risk Index scores made the DD strategy comparable to delaying transplant activities.

Conclusions: Cessation of transplant activity during the COVID-19 pandemic appears to be detrimental to long-term survival of ESRD patients, contributes to organ discard, and worsens the everlasting gap between organ supply and demand.

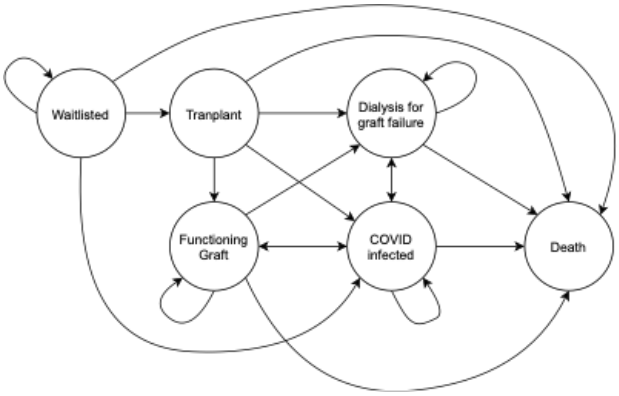

Figure 2. Two-way sensitivity analysis, Preferred Strategy as a function of SARS-CoV-2 Infection Rate and COVID-19 Pandemic Length by Candidate Age Groups

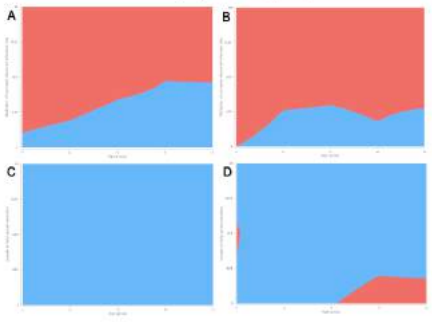

A: Multiplier of currently observed infection rates vs age group in LD (red) vs. "Hold LD" (blue) strategy; B: Multiplier of currently observed infection rates vs age group in DD (red) vs. "Hold DD" (blue) strategy; C: Length of hold period in months vs candidate's age group in LD (red) vs "Hold LD" (blue); D: Length of hold period in months vs candidate's age group in DD (red) vs "Hold DD" (blue) Abbreviations: DD: deceased donor; LD: living donor.

Abstract# LB 53

Influence of Vitamin D Status on the Prognosis of Covid 19 in Patients with Kidney Transplant

J. Ugalde-Altamirano, I. Revuelta, A. Carrillo, M. Xipell, F. Cofan, N. Esforzado, E. Montagud, G. Piñeiro, A. Molina, P. Ventura, D. Cucchiari, F. Oppenheimer, F. Diekmann, J. Campistol, B. Bayes, J. Torregrosa, *Nephrology, Hospital Clinic de Barcelona, Barcelona, Spain*

Purpose: The protective role of Vitamin D as an immunomodulator has been demonstrated in different pathologies included the viral etiology. This effect has been described by different mechanisms among these acting as an immunoprotein inducer, participates in growth and cell differentiation and acts as a mediator of apoptosis. Some evidence suggests that it could influence the SARS-COV 2 infection and its prognosis. Kidney transplant (KT) patients are more susceptible to 25 (OH) VitD (Calcidiol) deficiencies. The purpose of this study is to evaluate the Vitamin D status in transplant patients who have been diagnosed with COVID-19 and its possible correlation with prognosis.

Methods: It is an observational, retrospective, cross-sectional and descriptive study that includes kidney transplant patients diagnosed with COVID-19 and with serum 25 (OH) Vit D

Results: 79 patients were evaluated. The mean age was 58 years, 60.8% were men. 86% were KT, 11% were simultaneous pancreas and kidney transplant (SPK). 39 (48%) presented neumonia, 22 (28%)flu-like syndrom. 14 (17%) asymtomatic and 2(2,5%) fever. From this patients 39,2% had not changes in the antiinflamatorie therapy, 20.3%, required increased dose of corticosteroids, and 30.4% required methylprednisolone bolus or initiation of anti-interleukin therapy. The mean of Vit D was 21.41+/- 11% we found that 52% has Vit D <20 ng/ dl. 25% between 20 -30 ng / dl and 21,51% > 30 ng / dl

In 32 patientes who required intensification of treatment we found that 73% had Vit D levels <20 ng. 11 patients need an citical care unit, of these 62.5% had levels below <20 ng / dl. There were 12 deaths. 66% of deaths had vitamin D values <20 ng / dl.

Conclusions: We were able to observe that vitamin D levels could influence in the prognosis of SARS-COV 2 infection.

Vitamin D deficiency was found in a high percentage of transplant patients with COVID 19. Low levels of 25 OH Vit D were evidenced in patients who required greater intensification of antiinflamatory treatment and in deaths.

Abstract# LB 54

Short Term Outcomes in Previously Covid Positive Living Kidney Donors and Their Recipients

R. Prashar, N. J. Khoury, M. Ramesh, A. K. Patel, *Henry Ford Transplant Institute, Detroit, MI*

Purpose: Study short term outcomes of living kidney donors (LKD) who were previously infected with COVID 19, and in their recipients.

Methods: After a brief hiatus due to COVID March-May 2020, 33 living donor transplants have been performed at our center so far. Of these, we identified 3 consecutive LKD who were diagnosed with COVID prior to transplant. We collected retrospective data on clinical characteristics for these donors, and recipients of these previously infected donors. They were approved after meeting institutional requirements of resolution of COVID. Donors and recipients were required to have a negative Nasopharyngeal testing by NAT for SARS-CoV-2, 28 days post symptom resolution, and a repeat negative test 48 hours prior to transplant.

Results: Table 1 shows demographics, severity of COVID, timing of donation and post-donation course of the 3 LKD .

Patient No	Age at donation (years)	Gender	Race	Severity of COVID	Days post COVID diagnosis , when patient donated	Pre-donation eGFR (CKD-EPI using creatinine) (ml/min/1.73m^2)	Post-donation complications	Post-donation eGFR at 2 weeks (CKD-EPI using creatinine) (ml/min/1.73m^2)
D#1	22	Male	Middle Eastern	Mild	72	134	None	91
D#2	52	Female	Middle Eastern	Mild	50	105	Incidental finding of IgAN on post perfusion biopsy	58
D#3	22	Female	White	Mild	47	123	None	80

Mean time to donation from COVID diagnosis was 56 days. All had mild disease with no hospitalization. None had hematuria or proteinuria prior to donation. Post donation course was uncomplicated in all, with expected initial decline in GFR. In one (D#2), post-perfusion biopsy showed an incidental finding of IgA nephropathy (Oxford Classification 0). There were no viral particles on electron microscopy. There was patchy podocyte foot process effacement, believed to be from recurrence of FSGS in recipient(R#2). Clinical characteristics and post-transplant course of recipients of these LKD are shown in

Patient No	Age at donation (years)	Gender	Race	Severity of COVID	Days post COVID diagnosis , when patient donated	Pre-donation eGFR (CKD-EPI using creatinine) (ml/min/1.73m^2)	Post-donation complications	Post-donation eGFR at 2 weeks (CKD-EPI using creatinine) (ml/min/1.73m^2)
D#1	22	Male	Middle Eastern	Mild	72	134	None	91
D#2	52	Female	Middle Eastern	Mild	50	105	Incidental finding of IgAN on post perfusion biopsy	58
D#3	22	Female	White	Mild	47	123	None	80

One patient (R#1), previously had COVID. Post-transplant course was uneventful in 2 recipients. One (R#2) developed recurrence of FSGS immediately post-transplant. Her course was further complicated by COVID on post-op day 7, moderate in severity, managed by reduction in immunosuppression, bamlanivimab, steroids & remdesivir. While the exact exposure for this patient is yet to be determined, she appears to have contracted it from the community.

Conclusions: LKD with previously resolved COVID appear to have an uncomplicated immediate post-donation course. Recipients of LKD with resolved COVID tend to do well. Questions remain regarding optimal timing of donation and transplant after COVID resolution, to minimize risk of SARS-CoV2 transmission through tissue, even with negative nasopharyngeal PCR

Abstract# LB 55

Elevated Tacrolimus Levels in Hospitalized Organ Transplant Recipients with COVID-19

K. Mecadon[1], A. Hardesty[2], K. Vieira[3], R. Rogers[3], B. Merhi[4], A. J. Osband[5], G. Bayliss[4], R. Gohh[4], P. Morrissey[5], D. Farmakiotis[3], *[1]Department of Pharmacy, Rhode Island Hospital, Providence, RI, [2]Department of Internal Medicine, Residency, Warren Alpert Medical School of Brown University, Providence, RI, [3]Division of Infectious Diseases, Warren Alpert Medical School of Brown University, Providence, RI, [4]Division of Nephrology, Warren Alpert Medical School of Brown University, Providence, RI, [5]Department of Surgery (Transplantation), Warren Alpert Medical School of Brown University, Providence, RI*

Purpose: The effect of COVID-19 on immunosuppressant drug levels in organ transplant recipients (OTRs) has not been adequately studied.

Methods: We retrospectively studied hospitalized adult (>18-year-old) OTRs with COVID-19, who were receiving tacrolimus and were hospitalized between 3/1 and 12/16/2020. Categorical data were compared by Fisher's exact test, and continuous by the Mann-Whitney and Wilcoxon rank sum tests for unrelated or paired samples, respectively.

Results: We studied 30 OTRs. 67% were men, 90% had a kidney transplant. Two were heart transplant and one small intestine transplant recipients. Median age was 60.5 (range 21-84) years, median time from transplant 36 (range: 1-224) months. Tacrolimus troughs were significantly higher on admission for COVID-19 than baseline (average trough in the 6 months prior): median 11.5 vs. 7.4 ng/mL, P=0.001; Fig. 1. Patients with diarrhea had higher tacrolimus trough levels, compared to those without diarrhea (P=0.09). We found no significant association between tacrolimus trough and acute kidney injury or bacterial infections. Compared to OTRs with tacrolimus trough <10 ng/mL, those with trough >10 ng/mL were more likely to have elevated aspartate aminotransferase (AST) on admission (P=0.01, Fig. 2) and require supplemental oxygen during hospital admission (P=0.026, Fig. 1: black lines represent OTR requiring supplemental oxygen).

Conclusions: Tacrolimus trough levels were substantially elevated in most OTRs with COVID-19 at the time of hospital admission, compared to baseline. In OTRs with COVID-19, including outpatients, immunosuppressant drug levels should be closely followed; management of immunosuppression should be individualized.

Abstract# LB 56

Monoclonal Antibodies for Covid-19 in Patients with Solid Organ Transplant Recipients

L. Hasan[1], H. Hardgrave[2], T. Osborn[3], R. Dare[1], L. Burdine[4], E. Giorgakis[4], J. Rico[1], *[1]Internal Medicine, University of Arkansas for Medical Sciences, Little Rock, AR, [2]University of Arkansas for Medical Sciences, Little Rock, AR, [3]Surgery, University of Arkansas for Medical Sciences, Little Rock, AR, [4]Transplant surgery, University of Arkansas for Medical Sciences, Little Rock, AR*

Purpose: The FDA has issued Emergency Use Authorization (EUA) for monoclonal antibodies for the treatment of mild to moderate COVID-19 in patients at risk for progressing to severe disease. The authorized use includes treatment for patients with suppressed immune system (1,2). To our knowledge, there are no reports in the literature of Solid Organ Transplant Recipients receiving outpatient monoclonal antibodies for the treatment of mild to moderate COVID-19. We predict that SARS-CoV2 neutralizing antibodies infusion would help reduce hospital admissions and complications from SARS-CoV2 infection in this population.

Methods: In this retrospective descriptive study, we identified patients with kidney and/or liver transplant who were diagnosed with SARS-CoV2 infection in the outpatient setting with mild symptoms at the time of diagnosis and agreed to receive one of the two products available. 17 total patients were identified and followed by clinic visits or phone calls. Follow-up assessment included complications from Bamlanivimab infusion, resolution or progression of symptoms, hospitalizations, and outcome. The assessment was conducted at time of presentation and at least three weeks later.

Results: Out of the 17 patients, 14 had kidney transplant, 2 had liver and only one had both. Eleven patients received monoclonal antibodies within 10 days of symptom onset, 3 received it beyond 10 days of symptom onset and 3 patients had an unknown duration of symptoms before infusion. Three out of 17 patients (17%) experienced side effects after infusion including fever, myalgia, generalized weakness and pruritus. There were no serious adverse events. Four patients were hospitalized with a mean length of stay of 3.75 days (1-7 days). There were no ICU admissions. All 17 patients were alive at 3-week follow up.

Conclusions: Infusion of monoclonal antibodies for the treatment of mild to moderate Covid-19 was a safe strategy for Solid Organ Transplant Recipients, reducing hospitalizations and mortality from SARS-CoV2 infections in such high-risk population.

Abstract# LB 57

Covid-19 in Renal Transplant Recipients: Experience of Lithuania

M. Miglinas[1], M. M. Janušaitė[2], E. Ašakienė[2], L. Vareikienė[2], *[1]Nephrology, Vilnius University Santaros Klinikos, Vilnius, Lithuania, [2]Nephrology, Vilnius University Santaros clinics, Vilnius, Lithuania*

Purpose: Renal transplant recipients are at increased susceptibility to many viral infections, including coronavirus disease 2019 (COVID-19). The purpose of this review is to define the effect of COVID-19 infection on Lithuanian patients after kidney transplantation.

Methods: We enrolled patients who underwent kidney transplantation and were diagnosed with COVID-19 infection before January 24th, 2021. Patients were prospectively monitored. Clinical features, management and outcomes were recorded.

Results: We report on 53 cases of COVID-19 infection in kidney transplant recipients (median age 51 (range 29-75), 53 % females, from a 661 follow-up patients after renal transplantation) in 4 Lithuanian hospitals. Most common symptoms included febrile fever, cough and dyspnea. 55 % patients required hospitalization. Chest x-ray showed both sided infiltration in 63 % of patients, 55 % required supplemental oxygen, 6.8 % needed mechanical ventilation or extracorporeal membrane oxygenation (ECMO). Immunosuppression was changed to Hydrocortisone in 35 %. Remdesivir was administered to 23 % of hospitalized patients, 30.7 % were treated with Dexamethasone. 31 % were admitted to an intensive care unit (ICU) after an average of 3 days after hospitalization. Even though 27 % of the hospitalized patients required kidney replacement therapy, no patients lost their allografts. Overall mortality was 27 %. At an average of 3.6 months post-diagnosis - 76 % of patients tested positive for anti-spike IgG SARS-CoV-2 antibodies.

Conclusions: The data of COVID-19 infection in Lithuania was similar to that reported in the general population. A standard treatment and strategy of immunosuppression adjustment was applied, with 27% mortality among kidney transplant recipients hospitalized with COVID-19 infection. 76 % of patients tested positive for anti-spike IgG SARS-CoV-2 antibodies after 3.6 months post-diagnosis.

Abstract# LB 58

Nurse and Nurse Practitioner-lead Monoclonal Antibody Initiative for Solid Organ Transplant (sot) Recipients with Covid-19

W. Cochran[1], R. Avery[2], D. Brennan[2], N. Lawrence[2], A. Brown[2], S. Sullivan[2], B. Adams[2], M. McCarthy[2], S. Ellis[2], F. Naqvi[2], E. Kraus[2], N. Alachkar[2], S. Alasfar[2], F. Al Ammary[2], J. Horn[2], L. Hartman[2], L. Fessler[2], S. Purekal[2], Z. Siddiqui[2], D. Carter[2], J. Ficke[2], M. Kantsiper[2], L. Boyer[2], I. Gupta[2], A. Gurakar[2], D. Ostrander[2], J. Langlee[2], S. Shoham[2], K. Marr[2], P. Shah[2], *[1]Johns Hopkins Comprehensive Transplant Center, Baltimore, MD, [2]Johns Hopkins, Baltimore, MD*

Purpose: Monoclonal antibody (mAB) infusion (bamlanivimab or casirivimab/imdevimab) for symptomatic, non-hypoxemic, high-risk outpatients with COVID-19 infection, is an available early intervention for COVID-19+ SOT recipients. We aimed to assess efficiency in time from diagnosis to treatment, and outcomes in a retrospective cohort of SOT recipients with COVID-19 who received mAB.

Methods: We developed a Nurse Coordinator-led initiative to screen, refer, and facilitate mAB infusion for COVID-19+ SOT recipients within 10 days of symptom onset. SOT recipients received electronic messaging to promptly report potential COVID-19 symptoms to the transplant team. Data were collected on time from symptom onset to diagnosis, mAB infusion, and follow-up > 21 days, and hospital admissions, disease severity, mortality, and rejection.

Results: 34 out of 36 referred SOT recipients with symptomatic COVID-19 disease without hypoxia received mAB therapy (3 heart, 8 lung, 16 kidney, 2 Liver-Kidney, 2 Pancreas-Kidney, 3 Kidney-Heart). Median time from symptom onset to diagnosis was 2 days and from date of diagnosis to mAB infusion was 4 days. Of those 34, 88% did not require hospitalization and recovered uneventfully. 12% required hospitalization for COVID disease progression, two on the same day as mAB infusion, and the other 2, more than 26 days post infusion. Of these, 2 patients had mild-moderate hypoxia, and 2 had critical disease. Only 1 patient died from COVID-19 complications and no episodes of rejection or graft loss were observed.

Conclusions: The Nurse Coordinator-led initiative efficiently facilitated mAB therapy for COVID-19+ SOT recipients and was associated with excellent outcomes. Compared to prior published COVID-19 outcomes in SOT recipients, patients who received mAB may have reduce hospitalization and low mortality. As mAB therapy may be underutilized in the general population, these results support efforts to educate transplant centers to implement efficient interventions for the screening and referral of COVID+ SOT recipients for mAB therapy.

Abstract# LB 59

Impact of Covid-19 Infection on Tacrolimus Levels in Solid Organ Transplant Recipients

K. Heagler, K. Tejani, S. Sanchez, *Loyola University Medical Center, Maywood, IL*

Purpose: Immunocompromised patients are considered to be at high-risk for infection with SARS-CoV-2 (COVID-19). There have been observations within the transplant community that patients infected with COVID-19 have increased tacrolimus trough levels. A common presenting symptom of COVID-19 is diarrhea, which is a risk factor for increased tacrolimus levels. COVID-19 treatment often includes remdesivir, a weak CYP3A4 inhibitor that may also lead to increased tacrolimus levels. The study purpose was to determine the effect of COVID-19 infection and associated treatments on tacrolimus levels.

Methods: This retrospective chart review evaluated all solid organ transplant recipients admitted inpatient to the study institution within 14 days of a positive COVID-19 PCR test. Patients were excluded if they were treated outpatient, were not on tacrolimus, or were initially treated at an outside hospital. Patients were considered to have a clinically significant increased tacrolimus trough level if their admission level was 20% or greater than their baseline. Baseline levels were defined as the most recent trough level on a consistent dose per pharmacist clinical judgement. A logistic regression was performed to evaluate potential risk factors for elevated levels.

Results: A total of 55 patients met inclusion criteria from March 1, 2020 to December 26, 2020. Baseline characteristics are listed in Table 1. The majority of patients were male (67.3%), kidney transplant recipients (63.6%), and Hispanic ethnicity (41.8%). A clinically significant increase from baseline was observed in 47.3% of patients on admission. When comparing baseline level to peak trough level, 72.7% of patients had a clinically significant increase (Table 2). Transplant type, tacrolimus formulation, presence of diarrhea, and treatment with remdesivir were not associated with increased tacrolimus trough levels.

Conclusions: In transplant patients admitted with COVID-19, 43.7% of patients and 72.7% had increased trough levels on admission and peak trough levels greater than 20% of baseline, respectively. Potential risk factors for elevated levels, including presence of diarrhea and treatment with remdesivir, did not significantly increase the risk of elevated tacrolimus levels. These findings suggest that infection with COVID-19 may be an independent risk factor for increased tacrolimus levels, but will require further investigation to determine the full effect. Increased tacrolimus trough level monitoring should be considered in solid organ transplant recipients infected with COVID-19 to avoid toxicities associated with supratherapeutic levels.

Table 1

Baseline Characteristics (N = 55)	
Male gender – n (%)	37 (67.3)
Kidney transplant recipient – n (%)	34 (63.6)
Hispanic ethnicity – n (%)	23 (41.8)
Tacrolimus IR formulation – n (%)	41 (76.4)
Age at time of infection, year [median (IQR)]	63.7 (49.9 – 68.9)
Time from transplant, year [median (IQR)]	3.3 (0.8 – 6.0)
Presence of diarrhea – n (%)	16 (29)
Treatment with remdesivir – n (%)	23 (41.8)
Treatment in ICU – n (%)	15 (27.3)

Table 2

Results (N = 55)	
BL TAC level (ng/dL), mean (± SD)	6.5 (± 5.9)
AD TAC level (ng/dL), median (IQR)	6.9 (4.8 – 10.5)
PK TAC level (ng/dL), median (IQR)	10.5 (8 – 14)
Increase in level from BL to AD, % [median (IQR)]	9.6 (-32 – 79.8)
Increase in level from BL to PK, % [median (IQR)]	61.8 (16.7 – 165.1)
Clinically significant increased level on AD – n (%)	26 (47.3)
Clinically significant increased PK level – n (%)	40 (72.7)

Abstract# LB 60

Bamlanivimab for Covid-19 in Kidney Transplant Patients

M. Y. Jan, S. El-Sayegh, M. S. Yaqub, D. P. Mishler, O. Adebiyi, M. D. Anderson, T. E. Taber, A. Sharfuddin, *Nephrology, Indiana University School of Medicine, Indianapolis, IN*

Purpose: Treatment options for patients with COVID 19 have limited efficacy in reducing severity and duration of viral symptoms as well as progression to severe disease. Bamlanivimab(LY-CoV555) received Emergency Use authorization (EUA) by the FDA on November 9,2020 for non-hospitalized COVID 19 patients with mild to moderate illness who are considered high risk for progression to severe COVID 19 or to require hospitalization such as those on chronic immunosuppression therapy post-transplant. In this study we review its use among patients with kidney transplant.

Methods: 24 patients who tested positive for COVID 19 with nasopharyngeal PCR between November 9, 2020 and February 7, 2021 were retrospectively reviewed and analyzed. Labs, clinical course and communication with transplant team was reviewed. FDA approved standardized infusion dose was used.

Results: Average age of recipients was 57.5 +/- 11.8 years. Hypertension was most common co-morbidity in 17/24 patients followed by Diabetes Mellitus in 10/24. 3 patients had combined Pancreas Transplant, 1 combined-heart and 1combined- Liver. 3/24(12.5%) patients required hospitalization, and supplemental oxygen, while 1 patient required mechanical ventilation and died. Dialysis therapy for acute kidney injury was required in 1 patient. Majority of patients 14/24 were on Tacrolimus and Mycophenolic acid. 13/24 had no change to their immunosuppression after COVID diagnosis while 7/24 had mycophenolic acid decreased to half or lower and in 4 cases it was held temporarily. 1 patient each reported headache, elevated blood pressure after infusion. Among the 3 patients who were hospitalized 1 patient each was diagnosed with Aspergillosis and Histoplasmosis. Results summarized in Table 1.Table 1. Characteristics and outcomes among patients receiving Bamlanivimab, n=24

Age	57.5 +/- 11.8 Years						
Gender	Male 58.3% Female 41.7%						
Race:	Caucasian 83.3%, African American 12.5%, Hispanic 4.2%						
Type of Transplant:	LDKT 41.7%, DDKT 58.3%						
Co-Morbidities:	Hypertension 75%, Diabetes Mellitus (I and II) 41.7%%, Coronary Artery Disease 16.7%						
Time from kidney transplant to COVID 19	2828 +/- 2893 (mean) days, Median 1790 (19-11885) days						
IS Regimen Pre COVID	tac/mpa 58.3% (n=14)	tac/mpa/prednisone 16.7% (n=4)	tac/sirolimus 8.3% (n=2)	cyc/mpa/Prednisone 8.3% (n=2)			
IS Regimen Post COVID	No change in IS 54.2% (n=13)	Decrease mpa by ½ or lower 29.2% (n=7)	Hold mpa 16.7% (n=4)				
Time from COVID diagnosis to mab	2.25 (mean)+/- 2.1 days	1 (median) (1-9) days					
Hospitalizations	3	Supplemental Oxygen 3/3	ICU Admissions 2/3	Ventilator 1	Mortality 1		
AKI	3	AKI requiring RRT	1				
Dexamethasone	16.7% (n=4)	Remdesivir 8.3% (n=2)	Convalescent Plasma 1/24 4.2% (n=1)				
Common Symptoms	Cough 29.2%	Fatigue 29.2%	Fever 20.8%	SOB 20.8%	Headache 16.7%	Loss of taste/smell 12.5%	Asymptomatic 16.7%

Living Donor Kidney Transplant, DDKT Deceased Donor Kidney Transplant, MPA mycophenolic acid, IS Immunosuppression, Tac. Tacrolimus, Cyc. Cyclosporin, RRT Renal Replacement Therapy, mab. monoclonal antibody

Conclusions: To our knowledge this is the first report describing the use of Bamlanivimab in patients with Kidney Transplants. It showed a beneficial effect in immunosuppressed patients with mild to moderate COVID 19 symptoms with majority avoiding hospitalization. It appears to be well tolerated with no significant major adverse effects or allergic reactions in our cohort. Further large scale studies are needed to evaluate its impact on symptom duration and decrease in severity of COVID 19 among patients on immunosuppression for kidney transplant.

Abstract# LB 61

Impact of a "COVID-free" Pathway on Living Donor Transplantation During a Pandemic

S. Koganti, Y. Cheah, C. J. Simon, M. Tobon Lascano, J. Kim, M. E. Akoad, *Lahey Hospital & Medical Center, Burlington, MA*

Purpose: COVID-19 pandemic has significantly decreased rates of organ transplantation, with most programs curtailing living donor transplantations. This has led to an increase in waitlist deaths. We implemented a "COVID-free" pathway to minimize the risk of COVID infection in living donors and recipients to enable resumption of living donor transplantation.

Methods: The pathway consisted of a three-tier testing, quarantine and screening strategy (fig1). Most outpatient appointments were changed to televisits. Inpatients were roomed in units that do not have COVID patients. Rationale for the pathway was based on available data on the transmissibility dynamics of SARS-CoV-2 virus. We prospectively analyzed the impact of the pathway implementation on the number of living donor liver and kidney transplantation and its relationship to community 7-day COVID testing positivity rate, and COVID-related outcomes.

Results: A total of 54 patients (28 living donors and 26 living donor recipients) entered the COVID-free pathway from April 2020 until February 2021. Unsuspected asymptomatic COVID infection was detected in a living donor and kidney recipient pair (spouses) using our testing protocol which led to a postponement of their procedures. The rest of the living donor and recipient procedures proceeded as scheduled. None of the donors or recipients became infected with COVID during their hospitalization. One of the living donor liver recipients contracted COVID after discharge. The postponed pair who tested positive tested negative 2 months later with appropriate seroconversion and underwent uneventful donor nephrectomy and kidney transplantation. The rate of living donor transplantation was inversely related to the local COVID-19 positivity rate (fig2).

Conclusions: Our "COVID-free" pathway was useful in avoiding surgery in unsuspected infected living donor and their recipients. The comprehensive pathway allowed us to resume living donor transplant activity during the pandemic, though does not completely protect our patients after discharge.

Abstract# LB 62

Quantification of Multiple Isotypes of Anti-SARS-CoV-2 Antibodies in Kidney Transplant Recipients

J. S. Maltzman[1], L. Wang[1], P. Ahearn[1], T. Yalamarti[1], M. Menon[2], Y. Azzi[3], M. Melcher[1], M. Fernandez-Vina[1], R. Bray[4], H. Gebel[4], E. Woodle[5], E. Akalin[3], A. Girnita[1], P. Cravedi[2], *[1]Stanford University, Palo Alto, CA, [2]Icahn School of Medicine, NYC, NY, [3]Einstein School of Medicine, NYC, NY, [4]Emory University, Atlanta, GA, [5]University of Cincinnati, Cincinnati, OH*

Purpose: Solid organ transplant recipients are at increased risk of severe outcomes with infection by SARS-CoV-2, the etiologic agent of COVID-19. Antibodies directed against the virus are thought to offer protection and monoclonal antibodies directed against the virus have been used therapeutically. However, a thorough characterization of anti-SARS-CoV2 immune globulin isotypes in organ transplant recipients has not been reported.

Methods: Using a semi-quantitative Luminex-based multiplex assay, we determined antibody levels from 48 SARS-CoV-2 PCR+ hospitalized kidney transplant recipients. We measured total IgG, IgM, IgA and IgG subtypes of antibodies directed against 5 distinct viral epitopes including the nucleocapsid protein as well as multiple regions of the spike protein including the receptor binding domain.

Results: We identified multiple patterns of antibody responses. Specifically, 5 subjects were seronegative and 29 subjects had IgM, IgG and IgA antibodies specific for multiple epitopes of SARS-CoV-2. The 14 remaining subjects displayed a mixture of immunoglobulin isotypes. Of three subjects indeterminant for IgG antibodies, two had developed IgM, suggesting that they were early in the course of their immune response. Longitudinal samples from one subject demonstrated dynamic changes from IgM^+IgG^+ --> IgM^-IgG^+. Utilizing the semi-quantitative aspect of the assay, we found that IgG antibodies to the full Spike and Spike S1 domains were present at a statistically reduced level compared to immunocompetent controls while those directed against the Spike S2 domain were statistically higher. Interestingly, 77% of these subjects had detectable IgA directed against combinations of spike and/or nucleocapsid specificity. IgG subtype analysis and correlation between antibody expression patterns with clinical severity is under investigation.

Conclusions: Overall, these studies indicate that solid organ transplant recipients have the capacity to mount a dynamic antibody response to SARS-CoV-2 infection and that this response differs from immunocompetent individuals.

Abstract# LB 63

Donor-specific Anti-HLA Alloantibody in Kidney Transplant Recipients with COVID-19 Exhibit a Different Immunoglobulin Class and Subclass Profile When Compared to Anti-SARS-CoV-2 Antibodies

A. Girnita[1], L. Wang[1], M. Fernandez-Vina[1], E. Woodle[2], P. Ahearn[1], T. Yalamarti[1], M. Menon[3], Y. Azzi[4], M. Melcher[1], R. Bray[5], H. Gebel[5], E. Akalin[4], P. Cravedi[3], J. S. Maltzman[1], *[1]Stanford University, Palo Alto, CA, [2]University of Cincinnati, Cincinnati, OH, [3]Icahn School of Medicine, NYC, NY, [4]Einstein School of Medicine, NYC, NY, [5]Emory University, Atlanta, GA*

Purpose: Both anti-HLA and anti-SARS-CoV-2 antibodies target protein antigens. The aim of the present study was to compare the class and subclass profile of such antibodies in a cohort of kidney transplant patients.

Methods: We detected and identified anti-HLA and anti-SARS-CoV-2 antibody in 48 kidney transplant recipients who were hospitalized for SARS-CoV-2 PCR+ infection. Anti-HLA antibodies were detected by single-antigen bead Luminex assay, with IgG class, and IgG1-2-3-4 subclass secondary antibody. Anti-SARS-CoV-2 antibodies were also detected by Luminex assay directed against 5 distinct viral epitopes including the nucleocapsid protein as well as multiple regions of the spike protein. The secondary antibodies addressed total IgG, IgG1-2-3-4, IgM and IgA class/subclasses.

Results: The antibody profile (Table 1) included 12/48 cases of donor-specific anti-HLA antibodies, and 43/48 cases with anti-SARS-CoV2 antibodies. The majority of HLA-specific antibodies targeted HLA-DQ, with a dominant IgG class and an IgG1+IgG2+IgG3 subclass prevalence. However, anti-SARS-CoV2 antibody profile was characterized by increased prevalence of IgM (38/43, 79%) and IgA (41/42, 85%), and a lower prevalence of IgG2.

Conclusions: Overall, these data suggests that kidney transplant recipients with Covid-19 exhibit a humoral immune response both to donor-HLA and SARS-CoV-2. Although both are protein antigens, the allo-immune response has a high-IgG/low IgA pattern, while the Covid-19 antibody profile includes high IgA. Additional follow-up is needed to determine if the increased IgA is a consistent marker of anti-SARS-CoV-2 antibody response.

Patients	N = 48	%
Anti-HLA Antibody	43	90%
DSAs	12	25%
Class II DSA	12	100%
Class I DSA	1	8%
HLA-DR DSA	3	25%
HLA-DQ DSA	9	75%
HLA-DP DSA	2	17%
Total IgG DSA	12	100%
IgG1 DSA	11	92%
IgG2 DSA	6	50%
IgG3 DSA	9	75%
IgG4 DSA	0	0%
Anti-SARS-CoV2 Antibody	43	90%
IgG	42	88%
IgM	38	79%
IgA	41	85%
IgG1	41	85%
IgG2	10	21%

Abstract# LB 64

High Levels of Sars-cov-2 Detected in Immunosuppressed Covid-19 Patient Environments Weeks Following Initial Positive Test

C. E. Kuschner[1], Z. Brune[2], L. B. Becker[1], L. Teperman[1], *[1]North Shore University Hospital, Manhasset, NY, [2]Feinstein Institutes for Medical Research, Manhasset, NY*

Purpose: COVID-19 is a novel viral illness associated with significantly worse mortality, prolonged disease course, and extended periods of viral shedding in transplant patients on long-term immunosuppression. While prior case series have demonstrated extended disease duration in immunosuppressed kidney transplant patients, few have quantified the differences in viral shedding between immunosuppressed and immunocompetent patients. We provide the first case series demonstrating that immunosuppressed transplant patients have significantly higher viral loads, as measured through non-invasive environmental sampling.

Methods: We quantified viral particles on representative surfaces from the rooms of two patients on tacrolimus therapy with a history of renal transplant and compared against non-immunosuppressed patient. All patients had a SARS-CoV-2 positive nasopharyngeal swab within 48 hours of sampling and were symptomatic. Matched non-transplant patients were 3-4 days from initial symptoms while transplant patients were 3-4 weeks. Samples were collected using polyester-tipped swabs pre-soaked in DNA/RNA Shield (Zymo Research) for 1 minute. One-step quantitative real time-polymerase chain reaction performed using TaqPath 1-Step qRT-PCR Master Mix on the LightCycler® 480 System. Samples were run in triplicate for N1 and N2 primers and probes (IDT) recommended by the CDC. The viral copy count from each raw sample was divided by its respective surface area to calculate viral copies/cm^2.

Results: Despite the increased time between initial positive test result and sample collection, kidney-transplant patients on tacrolimus therapy demonstrated higher viral loads on associated bedrails, flooring, and bathroom flushes compared to the matched, non-immunosuppressed patients.

Patients	Bedrail (copies/cm²)	Floor beneath patient (copies/cm²)	Medication Dispenser (copies/cm²)	Bathroom Flush (copies/cm²)
Transplant A	549.1	78,292.2	19.2	1,528.7
Transplant B	105.8	674.9	437.9	74,864.8
Non-Transplant A	123.4	0.8	12.0	0
Non-Transplant B	0.4	0	0	0

Conclusions: This data raises a warning that immunocompromised individuals may shed higher levels of virus into their environment, likely through both aerosol and fecal mechanisms. Previous research has shown non-immunosuppressed individuals carry diminished environmental shedding by 21 days and may be safe to return to public service and general hospital floors, yet no similar analysis has been performed on immunosuppressed transplant patients. Our findings suggest that hospitals must take extensive isolation precautions when treating immunocompromised patients who have tested positive for SARS-CoV-2 due to the potential increase in the quantity of infectious virus particles.

Covid-19 Infections Post-liver and Kidney Transplantation in a Southern Ca Program

M. E. de Vera[1], J. Woloszyn[2], S. Regmi[2], R. Rattanavich[2], M. Rakoski[2], M. Lin[2], P. Mehta[2], A. Kore[2], J. Weissman[2], C. Martens[2], T. Phan[2], B. Jerez-Aguilar[2], M. Robinson[2], E. Wells[2], R. Villicana[2], M. Nguyen[2], *[1]Loma Linda University Health, San Bernardino, CA, [2]Transplant Institute, Loma Linda University Health, San Bernardino, CA*

Purpose: Southern CA is at the epicenter of the Covid-19 pandemic. We reviewed outcomes of our center's liver, kidney, and pancreas transplant patients stricken with Covid-19 infection.

Methods: Retrospective review of 161 post-transplant patients with Covid-19 infection.

Results: From March 2020 to January 2021, 43 liver, 107 kidney, 6 liver/kidney, and 4 kidney/pancreas patients came down with Covid-19 (TABLE). Transplants were performed from August 2000 to December 2020. Mean age was 54±1 yrs. Median time of infection was 27 months post-transplant (range 15 days to 21 years). Frequency of symptoms were: shortness of breath (55%), fever (52%), muscle aches (48%), diarrhea (36%), headaches (34%), loss of taste or smell (27%). Only 10 (6%) pts were asymptomatic. Overall mortality rate was 20% (33/161) and severe Covid-19 (hospitalization and death) occurred in 90/161 (56%) patients. Mortality risk factors included older age (62±2 vs 52±1 yrs, p<0.01), hospitalization (32/33, 97% vs 59/128, 46% p<0.01), mechanical ventilation (30/33, 91% vs 4/128, 3% p<0.01); there was no difference in gender (p=0.5), race (p=0.88), presence of diabetes (p=0.26), hypertension (p=0.06), or obesity (p=0.83). Liver/kidney recipients had the highest mortality rate (Table). Risk factors for severe Covid-19 included age (56±1 vs 51±2 yrs, P=0.01) and presence of diabetes (54/90, 60% vs 29/71, 41% p=0.02); there was no difference in gender (p=0.97), race (p=0.39), presence of hypertension (p=0.09), or obesity (p=0.82). Kidney patients had more severe Covid-19 than the other organ recipients. Kidney/pancreas patients were younger and tended to have mild infection and had no mortality. 156 (97%) patients were on tacrolimus (2 were on CyA, 2 on belatacept), 113 (70%) on MMF, and 127 (79%) on prednisone. 101 (63%) of patients were on triple immunosuppression. MMF was the most common agent to be adjusted (48/113, 42%) followed by tacrolimus (9/156, 6%). Of the 90 pts hospitalized, 70 (78%) received steroids, 30 (33%) received Remdesivir, and 53 (59%) were anticoagulated. 5 patients received convalescent plasma. Peak C-reactive protein levels when measured were significantly higher in patients who died (53.7±15.8 vs 19.8±5.3 mg/L, p=0.02).

Conclusions: Covid-19 infection inflicts a high mortality rate in liver, kidney, and pancreas transplant recipients.

Data and Demographics				
	Liver (n=43)	Liver/kidney (n=6)	Kidney (n=107)	Kidney/pancreas (n=4)
Age	58±13	54±16	54±18	42±8 (p<0.01)
Gender (M:F)	26:17	5:1	58:49	1:3
Severe Covid-19	19/43 (45%)	3/6 (50%)	67/107 (63%)	1/4 (25%)
Mortality	6/43 (14%)	3/8 (37%)	24/107 (22%)	0/4

Abstract# LB 66

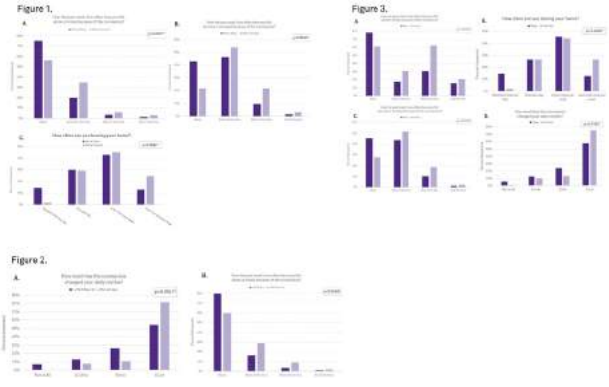
White, Older Men Are Less Affected by the Changes of the Covid-19 Pandemic

R. J. Berkowitz, A. Daud, S. Brietigam, T. S. Taylor, J. Carter, M. A. Callegari, B. Borja-Cacho, J. C. Caicedo, D. Simpson, D. P. Ladner, *Surgery, Northwestern Medicine, Chicago, IL*

Purpose: This study explores quality of life and lifestyle changes due to the COVID-19 pandemic among pre- and post- liver (LT) and kidney (KT) transplant patients across race, age, and gender.

Methods: Patients listed (pre) for liver transplant (LT) or kidney transplant (KT) and recipients (post) of LT and KT were prospectively enrolled at a large single center from 5/2020 - 1/2021. Demographics were collected from the EHR. The Chicago COVID-19 Comorbidities (C3) survey was administered via phone by trained research assistants to ascertain patient knowledge about COVID-19. Chi-Square or Fisher's Exact tests were used (p<0.05).

Results: A total of 310 pre- and post-LT and KT patients were enrolled (Table 1), with 187 (60%) KT patients and 122 (40%) LT patients. The mean age group for the cohort was 55-64, 104 (34%) were female, 228 (74%) were White, 45 (15%) were Black, 43 (14%) were Hispanic, and 251 (87%) had some college education. 26 (8%) patients had known COVID-19, 22 (85%) were post- LT or KT. There were no significant differences in COVID-19 diagnoses between genders or organ category (Table 2).



Compared to men, women felt lonelier (Fig 1A, p=0.0159), more nervous or stressed (Fig 1C, p= 0.0138), and left their home less frequently (Fig 1B, p= 0.0006) due to the pandemic. Specifically, white men left their homes more (Fig 3C, p= 0.0092) than white women, and a higher percentage of white men "never" felt nervous or stressed (Fig 3B, p= 0.004) or were "never" lonely because of the coronavirus (Fig 3A, p=0.0321) compared to white women. Further, women ≥55 reported that their routines changed more (Fig 2A, p= 0.0041 and felt lonelier (Fig 2B, p= 0.0249) than men ≥55 because of the coronavirus.

Figure 1.

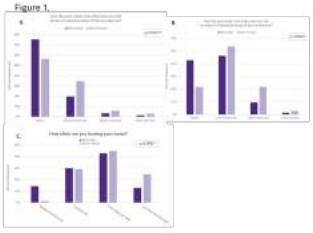


Figure 3.

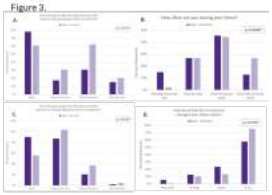

Figure 2.

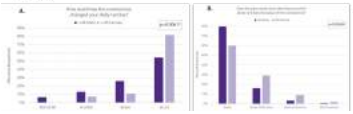

Conclusions: It has been previously demonstrated that women have shouldered a bigger mental health burden during the pandemic. Our findings show that this holds within the transplant population across age and race. Though our population is primarily male and chronically ill, that did not seem to affect behaviors and attitudes towards COVID-19. Thus, targeted social support for this particularly vulnerable population may be beneficial in closing this mental health gap.
