Conclusions: Treg-LEC LTα-LTβR interactions are important for Treg migration, stability and suppressor function. Disruption of the interactions results in poor migration, increased retention in graft, loss of Foxp3 expression, and thereby the ability to protect the allograft. The exTreg have the potential to become T effector cells and cause allograft rejection. ExTreg conversion can be prevented therapeutically by inhibiting IL-6 or LTβR NFκB, or by stimulating A2AR.

Abstract# 259

CEACAM1 Signaling is Essential to Elicit Tim-3 Inhibitory Regulation in Liver Transplantation

H. Kojima, H. Hirao, T. Ito, K. Kadono, K. J. Dery, F. M. Kaldas, J. W. Kupiec-Weglinski, *The Dumont-UCLA Transplantation Center, Los Angeles, CA*

Purpose: T cell immunoglobulin domain and mucin domain-3 (TIM-3) has been reported to induce T cell exhaustion. By alleviating hepatic ischemia-reperfusion injury, we have explored whether activation of TIM-3 function may be explored as a novel therapeutic target in orthotopic liver transplantation (OLT). Although carcinoembryonic antigen cell adhesion molecule 1 (CEACAM1) was recently discovered as a novel cellular TIM-3 ligand, whether and how CEACAM1/TIM-3 signaling axis can affect OLT outcomes remains unknown. We have generated TIM-3 transgenic/CEACAM1 knockout (TIM-3Tg/CC1KO) double-mutant mice to investigate the role of CEACAM1/TIM-3 axis on host CED4+ T cells in OLT.

Methods: In a clinically-relevant mouse OLT model, wild-type (WT; C57BL/6) livers, subjected to the extended cold storage (4°C/18h) in UW solution, were transplanted to groups of: WT, TIM-3 Tg, TIM-3 Tg/CC1 KO, and CC1 KO mouse recipients. Liver graft and serum samples were collected at 6h post-reperfusion. Mouse splenocytes from these animals groups were probed in standard cell activation culture systems. Human liver graft biopsies (2h post-reperfusion), collected from 55 adult OLT patients, were analyzed for immunological status by Western blots/RT-PCR.

Results: CEACAM1 signaling, reduced hepatocellular injury in TIM-3 Tg recipient mice, compared to WT hosts, as evidenced by serum ALT/AST levels, and Suzuki's histological grading of WT-OLT (n=8/group, p<0.01). In contrast, in the absence of recipient CEACAM1, the alleviation of WT-OLT injury in TIM-3 proficient recipients of double-mutants was curtailed (TIM-3 Tg/CC1 KO versus WT: n=7/8, p=0.737; TIM-3 Tg/CC1 KO versus CC1 KO: n=7 per group, p=0.11), suggesting CEACAM1 was essential to elicit TIM-3 inhibitory regulation in OLT. In agreement with our in vivo findings, RT-PCR analysis revealed that splenocytes from TIM-3Tg/CC1KO mice were highly susceptible to CD3 stimulation, while TIM-3 proficient T cells were immune suppressive. In the clinical arm, the expression of TIM-3 gene was significantly and negatively correlated with mRNA levels coding for TLR4, CD68, CD80, CD86, CXCL10, and cathepsin G in human OLT liver samples.

Conclusions: CEACAM1 serves as a critical ligand for TIM-3 to suppress T cell activation, leading to alleviation of liver innate immune-driven injury in the peri-transplant period.

Abstract# 260

Laminins Differentially Regulate Adaptive Alloimmune Responses

L. Li[1], M. Shirkey[1], W. Piao[1], Y. Xiong[1], V. Saxena[1], T. Zhang[1], J. Iyyathurai[2], R. Lakhan[1], R. Abdi[3], J. Bromberg[1], *[1]Surgery, UMB, Baltimore, MD, [2]CVID, UMB, Baltimore, MD, [3]Harvard University, Boston, MA*

Purpose: Lymph node (LN) stromal cell expressed laminin α4 (Lama4) and laminin α5 (Lama5) fibers are associated with tolerance and immunity, respectively. They regulate cell trafficking within the LN. We hypothesized that stromal Lama4 and Lama5 differentially regulate specific alloimmune responses.

Methods: LN stromal Lama5 conditional KO and Lama4 conditional KO mice on a C57BL/6 background were established. Littermate control (WT) and Lama5 KO mice received BALB/c donor-specific splenocytes (DST), or DST plus anti-CD40L mAb for immune and tolerance induction, respectively. T cell receptor transgenic CD4 TEa cells recognizing alloantigen were adoptively transferred into recipients. TEa cell migration, distribution, activation, and differentiation were analyzed. BALB/c donor hearts were transplanted into Lama4, Lama5 KO and WT mice and graft survival measured.

Results: Alloantigen specific TEa cell activation to $CD44^{hi}CD69^{+}$ effector cells were lower in Lama5 KO LN compared to WT, indicating that depletion of Lama5 prevented T cell activation. Under tolerance conditions, activation induced cell death of TEa cells in LN was lower in Lama5 KO than WT, showing that inhibition of T cell activation preserved antigen specific T cells. Under both tolerance and immune conditions, TEa cell differentiation to Foxp3+ Treg and IL-17+ Th17 was altered, making the Foxp3:Th17 ratio higher in Lama5 KO than in WT. Low dose tacrolimus (2 mg/kg/d) treated Lama5 KO cardiac recipients had significantly prolonged allograft survival (mean survival time (MST) 89 days vs 27.5 days in WT, p<.002). Low dose anti-CD40L mAb treated Lama5 KO recipients also had prolonged allograft survival (MST 155 vs 91 days in WT, p=0.07). In contrast, tacrolimus treated Lama4 KO recipients had significantly shorter allograft survival (MST 11.5 days vs 18 days in WT, p<.002). Lama4 KO recipients receiving a single dose of anti-CD40L displayed a trend for decreased survival (MST 42.5 vs 60 days, p<0.01).

Conclusions: Depleting stromal Lama5 suppressed T cell activation, and channeled alloantigen specific T cell differentiation from inflammatory to suppressive regulatory phenotypes. Depleting stromal Lama5 also promoted Treg induction and inhibited Th17 differentiation, creating a tolerogenic niche to enhance cardiac allograft survival. LN stromal Lama4 is necessary for allograft tolerance. Targeting laminins on LN stromal cells could be efficient to modulate adaptive immune responses.

Abstract# 261

TIGIT Identifies Polyfunctional Donor-Specific CD4+ T Cells Lost After Kidney Transplantation

A. C. van der List, N. H. Litjens, M. G. Betjes, M. Klepper, *Nephrology and Transplantation, Erasmus MC, Rotterdam, Netherlands*

Purpose: Development of T-cell hyporesponsiveness to donor antigen may explain the substantial decrease in the risk for acute rejection in the years following kidney transplantation. The underlying mechanisms of donor-specific hyporesponsiveness (DSH) are largely unknown but may allow for lowering of immunosuppressive medication. This study aimed to test the hypothesis that donor-specific recipient T cells become hyporesponsive due to exhaustion from continuous stimulation by donor antigen.

Methods: Peripheral blood mononuclear cells (PBMCs) of stable kidney transplant recipients (N=17) before and 3-5 years after kidney transplantation were stimulated with CD3-negative donor cells for 18-24 hours. Donor-specific T lymphocytes were identified at the single-cell level by CD137 (marker for antigen-specific T cells) and characterized for exhaustion marker expression by multi-parameter flow cytometry. Analysis was performed through unsupervised and unbiased clustering using Flow Self-Organizing Map (FlowSOM), a dimensionality reduction technique. The FlowSOM clusters containing cells of a particular expression profile with significant differential abundance after transplantation were identified using the statistical method, edgeR, via diffcyt.

Results: Unexpectedly, our results do not demonstrate an increase in exhausted donor antigen-specific T cells post transplantation. Instead, the study shows a significant decrease in donor antigen-specific CD4+ T cells expressing T cell

immunoglobulin and ITIM domain (TIGIT) long after transplantation. Further analysis at earlier timepoints indicated that this decrease is already present at six months post transplantation. Although TIGIT is often thought of as a marker for exhausted T cells, characterization of CD4+ T cells expressing TIGIT revealed these cells to have a predominantly central and effector memory T cell phenotype and a highly polyfunctional cytokine expression profile.

Conclusions: This study has identified TIGIT as a marker for a previously undescribed polyfunctional donor-specific CD4+ T cell population whose decline after kidney transplantation may underlie the phenomenon of DSH. Prospective clinical studies could help determine whether a low frequency of donor-specific TIGIT-expressing CD4+ T cells could guide lowering of immunosuppressive drugs.

Abstract# 262

TOLS are Novel Regulatory TLOs with A B Cell Signature

I. Rosales[1], Q. Yuan[1], C. Yang[1], P. Russell[1], J. Madsen[1], A. Alessandrini[1], R. Colvin[1], -. AA and RC[2], *[1]Massachusetts General Hospital, Boston, MA, [2]Co-Senior Authors, Boston, MA*

Purpose: Our previous studies suggest that a DBA/2 kidney graft is accepted by a MHC-fully mis-matched C57/BL6 recipient. Accepted renal allografts exhibited lymphoid like structures containing numerus Foxp3+ T cells within 2 weeks of transplant, referred to as Treg-rich Organized Lymphoid Structures (TOLS). We have previously shown that depletion of Tregs results in the dissolution of TOLS and the rejection of the kidney allograft by day 6.The aim of this study is to do an in-depth analysis of the TOLS - investigating the time-course change of infiltrated cells in accepted mouse kidney allografts, which immune cells could be involved in the formation of lymphoid like structures, and the role CCR7 plays in the formation of TOLS.

Methods: DBA/2 donor kidneys were transplanted into C57/BL6 or CCR7 KO recipients that have undergone bilateral nephrectomy. Transplanted animals were sacrificed at week 1, 2, 3, and 6 post-transplant, kidney allografts were examined by H&E, immunohistochemistry staining, and Nanostring RNA analysis. Some renal allografts were digested by collagenase and mononuclear cells were isolated by density centrifugation subsequently, flow cytometry was then used to quantify the percentage of various immune cells.

Results: H&E staining showed widespread infiltration of immunes cells in the cortex of renal allografts at week 1, and the formation of TOLS can be observed by week 2, localized to small arteries. By week 6, these structures are highly defined, showing the appearance of lymphoid structures. IHC staining showed these structures contain mixtures of CD4+ and CD8+ T cells, Tregs, dendritic cells, B cells, and plasma cells. FACS data suggest 18.8% ± 4.4 of T cells in the TOLS at week 6 were Foxp3+ cells. IHC staining also showed TOLS are PDPN+ (podoplanin), LYVE-1+, and PROX-1+, demonstrating its lymphatic characteristics. TOLS are MECA79-, lacking high endothelial venules that are specific to inflammatory tertiary lymphoid organs. We observed decreased survival of CCR7 KO recipients transplanted with DBA/2 allo-kidneys. TOLS were smaller in kidney allografts from CCR7 KO versus WT recipients (0.40 ± 0.17 mm^2 vs 1.73 ± 0.39 mm^2, respectively, $p < 0.001$) with a decrease number of B cells when compared to allografts procured from B6 WT recipients (48% vs 75% B220+ cells, respectively, $p < 0.001$). Nanostring RNA analysis confirmed a B cell signature associated with accepted kidney allografts which was significantly reduced in CCR7 KO recipients.

Conclusions: TOLS seem to be unique structures in tolerized kidney allografts and their formation is dependent on the CCR7 pathway. They represent novel regulatory tertiary lymphoid organs, different from inflammatory TLOs. Nanostring analysis reveals an increased B cell signature associated with TOLS. How infiltrating immune cells are organized into TOLS and how these structures contribute to tolerance induction need to be further studied.

Abstract# 263

Successful Induction of Hematopoietic Chimerism by Dual Inhibition of Mcl-1 and Bcl-2 Without Myeloablative Treatments in Nonhuman Primates

T. Hirose, D. Ma, G. Lassiter, T. Kawai, *Center for Transplantation Sciences, Massachusetts General Hospital, Boston, MA*

Purpose: Induction of hematopoietic chimerism by donor bone marrow transplantation (BMT) is essential for achievement of allograft tolerance in clinical HLA mismatched kidney transplantation, while myelosuppressive toxicity of the radiation is yet to be solved. We have recently found that chimerism can be achieved with minimal total body irradiation in nonhuman primates (NHPs) by inhibiting Bcl-2 (anti-apoptotic protein) with Venetoclax (ABT-199). However, a minimal dose of TBI was still required for chimerism induction. Since Mcl-1, another member of the Bcl-2 family proteins, is highly expressed in hematopoietic stem cells (HSC) in bone marrow (BM), we hypothesized that Mcl-1 inhibition might delete the host HSC niche, thus facilitating donor bone marrow engraftment without TBI requirement.

Methods: HSC (CD34+CD90+CD45RA-) counts and Colony Forming Units (CFU) of BM aspirates were measured after treatment with ABT-199 (10mg/kg X11) alone (n=3), Mcl-1 inhibitor (S63845, 5mg/kg X 5) alone (n=3), or combination of both (n=3). In three recipients treated with the combination of S63845 and ABT-199, BMT from the MHC mismatched donor was performed. All BMT recipients were also treated with ATG (3 doses pre-transplant) and anti-CD154 and a 28 day-course of cyclosporine (CyA), all of which were included in our standard BM conditioning for NHPs (Fig. 1a). One NHP underwent skin transplantation after BMT.

Results: Monotherapy of ABT-199 or S63845 depleted CD34+ BM cells to 50 ± 13% and to 42±17% of pre-treatment levels, respectively. CFUs were also suppressed to 58 ± 8.6% and to 46 ± 17%, respectively. Combining ABT-199 with S63845 depleted more HSCs (22 ± 11%) with near complete depletion in two animals. CFUs were also effectively suppressed to 23 ± 8%(Fig. 1b). Since dual inhibition of both Mcl-1 and Bcl-2 most effectively depleted HSCs, BMT was perfomred using the combination of S63845 and ABT-199 (Fig. 1a). After conditioning, all recipients successfully developed multilineage chimerism, which lasted for 3 months (Fig. 1c) despite discontinuation of CyA at one month. Transplanted donor skin was engrafted, while two grafts from different third-party were rejected.

Conclusions: Dual inhibition of Mcl-1 and Bcl-2 effectively depleted BM HSC, leading to successful hematopoietic chimerism induction without myeloablative treatments and donor-specific tolerance. This approach may set the path for the development of a novel and clinically applicable protocol for induction of hematopoietic chimerism without myeloablative treatments.

Abstract# 264

Increased T Cell Cross-dressing in Accepted Kidney Allografts

Q. Yuan[1], S. Hong[2], E. Szuter[2], I. Rosales[2], Y. Zhao[2], B. Gonzalez-Nolasco[2], G. Benichou[2], P. Russell[2], J. Madsen[2], R. Colvin[2], A. Alessandrini[2], *[1]Massachusetts General Hospital/Chinese PLA General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, MA*

Purpose: Kidney allografts transplanted across certain mouse strain combinations (e.g. DBA/2 to B6) develop tolerance while other combinations do not (e.g. B6 to DBA/2). We have recently shown that a subset of infiltrating conventional and plasmacytoid dendritic cells in the accepted DBA/2 kidney allografts are cross-dressed. In certain tumor models, cross-dressing is observed in T cells and these cells are immunoregulatory. In this study, we looked at the frequency of recipient T cells cross-dressed with donor MHC in accepted kidney allografts.

Methods: DBA/2 donor kidneys were transplanted into C57/BL6 recipients. Recipients were sacrificed at several timepoints post-transplant, kidney allografts were examined by H&E and immunohistochemistry staining. Some renal allografts were enzymatically digested and mononuclear cells were isolated by density centrifugation; flow cytometry and image flow cytometry was then used to quantify the percentage of H-2K^b+H-2K^d cross-dressed T cells. Preliminary Nanostring RNA analysis was performed on sorted cross-dressed (XD) and non-crossed (nXD) CD4+ and CD8+ T cells.

Results: Transplantation of DBA/2J kidneys into B6 recipients resulted in the presence of cross-dressed T cells within the allograft as early as 6 days and persisting until 46 days post-transplantation shown by flow cytometry (Fig. 1) and further characterized by image flow cytometry (Fig. 2). Preliminary RNA Nanostring data show that XD CD4+ T cells contain exosomal transcripts (CD63, CD81, Lamp1,

Lamp2), as well as specific endothelial and epithelial transcripts, while XD CD8+ T cells do not, suggesting that XD CD8+ T cells may have undergone cross-dressing via trogocytosis. Cross-dressing was not appreciatively observed in rejecting allografts.
Conclusions: Our data suggest that cross-dressing of infiltrating recipients T cells correlates with kidney graft acceptance in a model of spontaneous tolerance.

BK virus in Kidney Recipients

Abstract# 265

VP2 MRNA Distinguishes the Direct Injury and Inflammation Effects of Polyoma Virus (BK) Infection from the Cognate TCMR Response That Follows Immunosuppressive Minimization

P. F. Halloran[1], K. Famulski[1], K. S. Madill-Thomsen[1], G. Böhmig[2], G. Gupta[3], M. Myślak[4], O. Viklicky[5], &. the INTERCOMEX Study Group[6], *[1]Alberta Transplant Applied Genomics Centre, Edmonton, AB, Canada, [2]Medical University of Vienna, Vienna, Austria, [3]Virginia Commonwealth University, Richmond, VA, [4]Pomeranian Medical University, Szczecin, Poland, [5]Institute for Clinical and Experimental Medicine, Prague, Czech Republic, [6]., Edmonton, AB, Canada*

Purpose: BK virus nephropathy (BKN) and T cell-mediated rejection (TCMR) are difficult to distinguish by histology but often coexist due to the necessity for immunosuppression minimization. We sought to use molecular changes to distinguish direct virus damage from cognate T cell activity.
Methods: We used microarrays to study molecular changes associated with histologically defined BKN in kidney transplant biopsies in the INTERCOMEX study. Molecular classifiers estimated parenchymal injury, inflammation, and TCMR in 1679 biopsies (55 with BKN). In a subset of 102 biopsies (50 BKN/52 no BKN, 26 TCMR/26 other abnormalities), we measured expression of BK capsid protein VP2 mRNA by RT-PCR to quantify viral activity.
Results: Top transcripts associated with BKN (Fig. 1A) reflected inflammation (e.g. CXCL13) and atrophy-fibrosis (e.g. IGKC immunoglobulin gene). Gene Ontology (GO) analysis revealed terms related to DNA replication.
VP2 mRNA identified BKN with AUC=0.94. VP2 expression was positive in 45/50 histologic BKN biopsies and negative in 46/52 control biopsies. GO analysis of VP2-associated transcripts (Fig. 1B) represented injury, atrophy-fibrosis, inflammation, with terms associated with mitosis and DNA repair, many shared with the BKN analysis in Fig. 1A.
Transcripts correlating with VP2 activity correlated with the BKN classifier but not the TCMR classifier, distinguishing BKN from TCMR (Fig. 1C). BKN/VP2 mRNA positive biopsies with molecular TCMR had severe tubulitis compared to BKN/VP2 positive biopsies with no TCMR, plus increased injury and atrophy-fibrosis (Fig. 1C). In 5 sets of serial biopsies, molecular TCMR scores increased as VP2 decreased, indicating distinct dynamics for direct virus injury vs. cognate T cell activity.
Conclusions: VP2 mRNA expression in BKN parallels virus-induced parenchymal injury and innate immunity, while molecular TCMR develops independently as an adaptive immune response. Heavy tubulitis in BKN indicates emergence of TCMR. Whether BK-specific adaptive immunity produces a molecular TCMR phenotype without alloimmunity requires further study. VP2 mRNA measurement could guide clinical management when BKN and TCMR coexist.

Abstract# 266

Coexistence of BKPyV Lytic Infection and Viral Integration in the Development of BKPyV Diseases After Renal Transplantation

S. Yan[1], Y. Wang[1], Y. Liu[1], W. Deng[1], Z. Yan[1], J. Xu[1], C. Wu[2], Y. Miao[1], *[1]Department of Organ Transplantation, Nanfang Hospital, Southern Medical University, Guangzhou, China, [2]Departments of Urology & Pathology, Massachusetts General Hospital, Harvard Medical School, Boston, MA*

Purpose: To understand the role of BK Polyomavirus (BKPyV) infection and integration in the pathogenesis of BKPyV-associated diseases.
Methods: Sixteen patients with BKPyV-associated diseases were included, 3 with BKPyV-viruria, 3 with BKPyV-viremia, 5 with BKPyV-associated nephropathy (BKVAN), and 5 with BKV-related urothelial carcinoma (Table 1). Viral copy numbers and virome capture sequencing were conducted in the samples of allograft, tumor, blood and urine.
Results: BKPyV integration was detected in all 16 patients (Table 1), including 5 of 5 biopsies of BKVAN allograft (1 of them also had viral integration in blood and urine), 5 of 5 tumor samples of BKPyV-associated urothelial carcinoma, in both urine and blood samples of 3 of 3 patients with viremia and 1 of 3 with viruria, and in urine samples of 2 of 3 patients with viruria. There is a significant difference in the average supporting reads of viral integration sites among the above samples (Fig. 1A). Similarly, increased microhomology-mediated end joining (MMEJ) patterns at

the integration sites were also observed in the tumor and BKVAN samples (Fig. 1B-C). Renal allografts from BKVAN recipients showed SV40-LTAg-positive cells by immunohistochemistry (Fig. 1D-E) and a large number of viral inclusions detected in renal tubular epithelial cells by electron microscope, indicating an active BKPyV lytic infection (Fig. 1F). Well-amplified integration sites (supporting reads > 300) were detected in the BKVAN allograft tissues, indicating a significant BKPyV integration.

Conclusions: We report in the study, for the first time to our knowledge, viral integration in patients with BKPyV-associated non-cancer diseases, including BKPyV viruria, BKPyV viremia, and BKVAN. In BKPyV-affected non-cancerous tissues, lytic infection and viral integration can co-exist. The increase of viral integration sites, likely affecting more key cellular genes, and the increased proportion of MMEJ integration pattern likely may contribute to the pathogenesis of the BKPyV-associated diseases.

Table 1. Viral load and integration in the patient cohort

*BKPyV: BK Polyomavirus; BKVAN: BKPyV-associated nephropathy; N/A: not available; NA: not applicable; Y, yes; N, no.

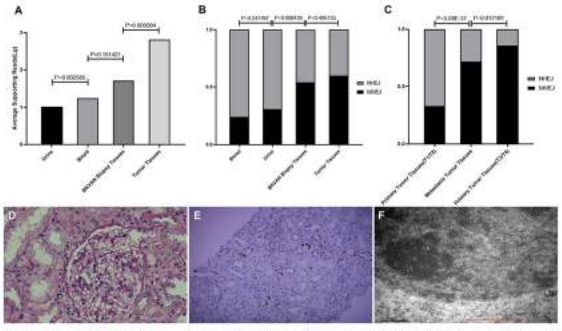

Figure 1. BKPyV lytic infection and virus integration in BKPyV-associated disease processes. (A) The average supporting reads of BKPyV integration sites differ in the four types of samples, suggesting that the role of viral integration becomes more significant along the disease progression. (B-C) The proportion of MMEJ integration increased with the progression of the disease. (D-F) The pathological findings of the renal allograft of Case 6. (D) light microscopy showed typical characteristics of BKPyV-associated nephropathy (hematoxylin and eosin staining, 400×): nuclear enlargement of a few renal tubular epithelial cells; basophilic viral inclusions were found in the nucleus; focal tubular atrophy, interstitial edema and multifocal infiltration of lymphocytes and plasma cells could be seen. (E) Immunohistochemistry showed SV40-TAg-positive cells in renal allograft tissue (100×); (F) electron microscopy showed a large number of intracellular viral inclusions(25000×). MMEJ, microhomology-mediated end joining; NHEJ, nonhomology-mediated end joining.

Abstract# 267

Duration and Magnitude of BK Viremia Do Not Predict Outcome in Patients After Kidney Transplantation

E. A. Farkash[1], J. T. Rajagopal[2], M. Vincent[2], M. D. Doshi[3], *[1]Dept of Pathology, Michigan Medicine, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]Dept of Nephrology, Michigan Medicine, Ann Arbor, MI*

Purpose: BK viremia was a major cause of kidney transplant failure in the early 2000's and remains a risk factor for subsequent rejection. The standard of care at our large transplant center now includes frequent testing for BK viremia and early reduction in immunosuppression. What are the features and outcomes of BK infection in the setting of aggressive monitoring and treatment?

Methods: We retrospectively analyzed the demographics and outcomes of 401 renal transplant recipients with BK viremia from 2/2006 to 8/2017. Demographic data, transplant type and outcome, biopsy reports, and BK viremia tests were collected from electronic medical records and laboratory information systems. Demographic data was analyzed by chi-squared and Fisher exact tests, and survival data was analyzed by effect likelihood ratio. (JMP v15, SAS).

Results: During the study period, there were roughly 2550 kidney transplants, corresponding to a 15.6% rate of BK viremia. Patients with BK viremia were of similar gender (253/401, 63.1% male) compared to the overall transplant population (62.2% male; p=0.74 by Fisher exact). 127 patients (31.7%) with BK viremia were non-white (97 African-American, 10 Asian, 20 Native American and other), similar to regional demographics. The proportion of living related (15.2%), living unrelated (23.9%), and deceased donor (60.8%) transplants were also similar to the overall transplant population (17.8%, 23.6%, and 58.6%; p=0.43 by chi-squared). In patients with BK viremia, there was no association between peak BK titer and risk of graft failure (p=0.93, likelihood ratio) or combined failure/death (p=0.98). Duration of BK infection correlated with better outcome (p=0.019 and 0.032), likely due to length bias. Graft half-life was similar for patients with BK viremia and nationally reported graft survival (deceased ~13 years, living ~16 years).

Conclusions: Kidney transplant recipients with BK viremia are demographically similar to the overall transplant population. In comparison to historical reports, BK infection does not affect graft failure and overall survival in a modern, aggressively managed cohort. Within the cohort of patients with BK viremia, severe or persistent infections also do not predispose to poor outcome. There were 734 biopsies on 348 of the patients in the study during active BK viremia or within 6 months after viral clearance, and future studies will examine the influence of histologic features during and after infection on graft survival.

Abstract# 268

Donor-Derived Cell-Free DNA Levels Risk-Stratify Polyoma BK Viremia and Associated Clinical Events After Kidney Transplantation - Preliminary Results from ADMIRAL Study

A. Pai[1], L. Bu[2], J. S. Bromberg[3], G. Gupta[4], I. Moinuddin[4], T. Alhamad[5], V. Bowers[6], S. Ghosh[7], W. Tian[7], E. Stites[8], S. Anand[9], *[1]University of Texas McGovern Medical School, Houston, TX, [2]University of Minnesota, Minneapolis, MN, [3]University of Maryland School of Medicine, Baltimore, MD, [4]Virginia Commonwealth University, Richmond, VA, [5]Washington University in St. Louis, St. Louis, MO, [6]Tampa General Hospital, Tampa, FL, [7]CareDx, Brisbane, CA, [8]University of Colorado, Aurora, CO, [9]Intermountain Medical Center, Murray, UT*

Purpose: The threshold of 10,000 copies for blood Quant BK PCR has been used as a surrogate for BK nephropathy (BKN) in kidney transplant recipients (KTR) and affects treatment decisions. We hypothesized that patients with BK viremia are heterogeneous in terms of clinical outcomes and may be optimally stratified when also assessing donor-derived cell-free DNA (dd-cfDNA) levels.

Methods: 883 visits from 246 patients were examined from the Assessing dd-cfDNA monitoring insights of renal allograft with longitudinal surveillance (ADMIRAL study; clinicaltrials.gov: NCT04566055219). All patients had dd-cfDNA (AlloSure®; CareDx) with standard post-transplant surveillance. All clinical events and BK Quant PCR were assessed. A high dd-cfDNA level was defined as >0.5% based on previous injury analysis in the ADMIRAL cohort.

Results: The distribution of BK PCR viral load demonstrated that majority of KTR were assessed as *asymptomatic.* In ADMIRAL (**FIGURE 1**), 96.5% of viremia KTR had Quant PCR < 10,000 copies and 3.5% >10,000 copies. No significant association was observed between dd-cfDNA and the PCR-based dichotomized BK classes (Kruskal-Wallis p-value:0.4237). No significant correlation was observed between dd-cfDNA levels and PCR copies (R:0.0088). However within this cohort of <10,000 copies, patients with elevated dd-cfDNA (>0.5%) levels had increased incidences for DSA (HLA) and allograft rejection (ABMR and TCMR) based on histopathology results (**FIGURE2**).

FIGURE 1:

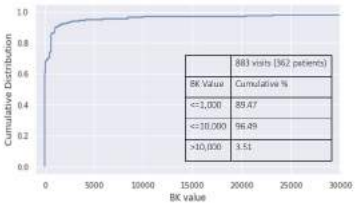

FIGURE 2:

BK PCR <10,000	AS >= 0.5	AS < 0.5	Chi-square; P value
Count	176	666	
DSA positive	17.05%	4.95%	4.10e-211
ABMR	14.20%	1.50%	1.95e-91
TCMR	6.82%	1.35%	1.17e-82
No rejection	11.36%	11.56%	

Conclusions: The utility of dd-cfDNA as a decision supporting tool, when modulating immunosuppression in response to the BK PCR magnitude, may provide benefit for detecting rejection. Higher levels of dd-cfDNA in the context of BK viremia are associated with increases of other adverse events, suggesting that BK PCR copies alone are insufficient to risk-stratify the severity of BKV graft injury. dd-cfDNA does not correlate with BK PCR copies and so provides additive information to interpretation.

Abstract# 269

Characterization of Retransplantation Following Graft Failure Due to Bkvn

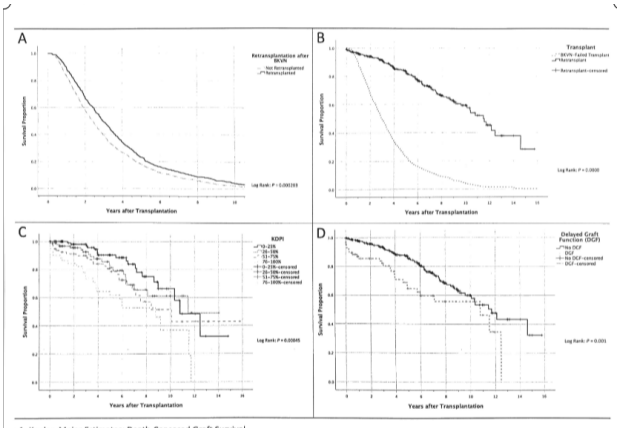
K. Nguyen[1], H. Curtis[2], J. Panichella[2], H. Resweber[3], A. Di Carlo[2], S. Karhadkar[1], *[1]Surgery, Temple University School of Medicine, Philadelphia, PA, [2]Surgery, Temple University School of Medicine, Philadephia, PA, [3]Surgery, Temple University School of Medicine, Gladwyne, PA*

Purpose: Immunosuppression following kidney transplantation allows for the reactivation of BK polyomavirus (BKV)- frequently implicated in graft dysfunction and failure. Although BKV Nephropathy (BKVN) was first described nearly fifty years ago, there is still inadequate understanding of the disease and a lack of specific therapies. For patients whose grafts fail due to BKVN, re-transplantation is a viable option that has not been extensively studied. This study further characterizes BKVN and subsequent re-transplantation in the most expansive population studied to date, geographically, temporally, and in magnitude.

Methods: The OPTN/UNOS database was used to identify patients who received kidney or kidney-pancreas transplantations between October 1, 1987 and December 31, 2018 that resulted in renal allograft failure attributed to BKVN (n=1587). This population was further divided into those who underwent kidney re-transplantation (n=495) and those who did not (n=1092). Subject characteristics were summarized using means and standard deviations or frequencies and percentages, as applicable. Significance between groups was determined by independent samples t-tests and χ^2 tests ($\alpha = 0.05$.). Death-censored graft survival for various subgroups was estimated using Kaplan-Meier with Log-Rank to assess significance. All analysis was completed using SPSS Statistics 26

Results: The cohort that was re-transplanted after BKVN failure was significantly younger and had fewer prior kidney transplants, lower EPTS scores at failure, lower rates of delayed graft function, and a greater proportion of living donors when compared to those who were not re-transplanted. Allograft lifespan prior to BKVN failure was significantly greater in the population that was re-transplanted than the population that was not. Among re-transplants, delayed graft function or high KDPI significantly decreased allograft lifespan. The re-transplanted allografts lasted significantly longer than the original grafts that had failed due to BKVN. Use of steroids for induction was found to have no significant impact on graft survival when compared to a steroid-free regiment.

Conclusions: Trends in and characteristics of successful re-transplantation after BKVN-associated graft failure, using the largest population of this type to date affirms viability of treatment of patients who lose grafts to BKVN and of re-transplantation following BKVN-associated graft failure.



1. Kaplan-Meier Estimates: Death-Censored Graft Survival
BKVN-attributed graft failures: Subsequently retransplanted vs. not retransplanted. B: Retransplanted patients: Original BKVN-failed transplant vs. retransplantation after BKVN: KDPI groups. D: Retransplantation after BKVN: Those who experienced DGF vs. those who did not

Abstract# 270

Transcriptomics and Proteomics Profiling of Complement Pathway (cp) Proteins in Biopsies With Polyomavirus Bk Nephropathy (bkvn)

P. Randhawa[1], F. Fei[2], Y. Huang[1], G. Tseng[3], K. Xiao[4], *[1]Departments of Pathology, Pittsburgh, PA, [2]Pharmacology and Chemical Biology, Pittsburgh, PA, [3]Biostatistics, Pittsburgh, PA, [4]Pharmacology and Chemical Biology, University of Pittsburgh, Pittsburgh, PA*

Purpose: Late stage BKVN can show C4d as well as classic immune complex deposits in the tubular basement membranes (Bracamonte et al. Am J Transplant 2007: 7: 152: Batal et al. Modern Pathology 2012: 43: 69). A comprehensive study of the role of complement in the pathogenesis of BKVN has not been performed.

Methods: RNA-seq, Tandem mass tag (TMT) isobaric labeling and label free quantitative profiling were used to interrogate a set of 15 allograft biopsies with equal representation of stable graft function (STA), healthy kidney (HKD), and BKVN. Data analysis consisted of reporter ion intensity relative quantification, log transformation, quantile normalization, and differential expression (DE) analysis by the R package "limma".

Results: In RNAseq data, 6201 genes were differentially expressed between BKVN and stable biopsies ($p<0.05$). This dataset was intersected with 326 human complement related genes downloaded from the European Bioinformatics Institute (EBI) website. This resulted in the identification of 44 genes associated with positive regulation of classical pathway (IGHM, IGHG1, IGHA1) or alternate pathway (CFD, a C3 proactivator convertase), and negative regulation of both the classical and lectin pathways (SERPING1 or C1-inhibitor). To date, 5 genes in the RNA-seq data have been validated by TMT or label free proteomics analysis. Immunoglobulin gene expression provides evidence for antibody-antigen complex driven activation of the classical complement pathways. Complement factor D (CFD) cleaves factor B to a noncatalytic chain Ba and a catalytic chain Bb. The active subunit Bb associates with C3b to form the alternative pathway C3 convertase. C1-inhibitor irreversibly binds to and inactivates C1r and C1s proteases in the C1 complex of classical pathway, as well as the MASP-1 and MASP-2 proteases in the MBL complexes of the lectin pathway.

Conclusions: Complement proteins play a role in the pathogenesis of virus mediated tissue injury in BKVN. This observation opens up the possibility of exploring anti-complement therapies in a subset of patients with C4d staining or immune complex deposits in the tubular basemen.

Abstract# 271

Efficacy of MAU868, a Novel BKV Neutralizing Monoclonal Antibody (mAb), for the Treatment of Severe BK Virus Nephropathy (BKVN) After Kidney Transplant

S. C. Jordan[1], N. Ammerman[2], M. Toyoda[3], K. Lim[2], J. R. Abend[4], A. Patick[5], M. R. Hodges[5], A. Vo[2], S. J. Kovacs[6], *[1]Comprehensive Transplant Center, Cedars Sinai Medical Ctr, West Hollywood, CA, [2]Comprehensive Transplant Center, Cedars Sinai Medical Ctr, Los Angeles, CA, [3]Cedars Sinai Medical Ctr, Los Angeles, CA, [4]Novartis Institutes for BioMedical Research, Virology Research, Emeryville, CA, [5]Amplyx Pharmaceuticals, San Diego, CA, [6]Novartis Institutes for BioMedical Research, Translational Medicine, East Hanover, NJ*

Purpose: BKV reactivation leading to nephropathy and allograft loss in kidney transplant (KT) recipients remains a clinical significant concern. No specific or effective anti-BKV therapies exist. Clinical management involves reduction of immunosuppression (IS), which increases the risk of acute graft rejection. MAU868 is a novel, human mAb (IgG) directed against the major BK viral capsid protein, VP1. In vitro, MAU868 potently neutralizes all 4 major BKV genotypes, has a high barrier-to-resistance and a long half-life (range 23-30 days). Data are presented from the first 2 patients with BKVN treated with MAU868, under separate single patient expanded access programs.

Methods: Patient 1 is a 31 YO female with ESRD due to SLE and on HD for 3 yrs, underwent A2→B pediatric en-bloc DDKT. Patient 2 is a 67 YO male with history of idiopathic pulmonary fibrosis who underwent his second KT after the first was lost to BKVN. BK viremia developed in both patients and persisted despite IS reduction and treatment with IVIG. Patient 1 had biopsy-confirmed BKVN.

Results: Patient 1 initially received 3 IV doses of MAU868 20 mg/kg monthly. The sCr and BK viremia decreased from 2.4 to 1.6 mg/dl and by 1.0 log10 copies/ml, respectively. Biopsy also showed improvement in BKVN. Eight additional doses of 20 mg/kg were administered biweekly with no further improvements. More than 2 yrs PT, BK viremia remained $<10^4$ log10 copies/mL, sCr was 3.0 mg/dl and dialysis has not been required. Patient 2 received 5 IV doses of MAU868 20 mg/kg monthly with sCr and eGFR remaining stable (~60 ml/min/1.73m^2). BK viremia decreased by 1.0 log10 copies/ml and is $<10^3$ log10 copies/ml 4 months after the last dose. MAU868 was safe and well-tolerated in both patients.

Conclusions: MAU868 treatment of 2 patients with active BKVN was associated with viral load reductions and improvement or stabilization of renal function. The clinical utility of MAU868 for the prevention and/or treatment of BKV disease warrants further clinical investigation in randomized, controlled clinical trials because the medical need for a specific anti-BKV therapy remains unmet and the experiences reported here suggest benefit is possible.

Abstract# 272

Immunosuppression Reduction Strategies for Polyoma BK Viremia in Kidney Transplant Patients on Belatacept-Based Immunosuppression

O. Roe[1], E. Meredith[1], A. Reid[2], A. Basu[3], *[1]Emory University Hospital, Atlanta, GA, [2]University of California San Francisco Medical Center, San Francisco, CA, [3]Emory Transplant Center, Atlanta, GA*

Purpose: The mainstay of treatment for BK infection is immunosuppression (IS) reduction, however limited literature provides guidance for treatment of patients with a belatacept-based IS regimen. Our center primarily utilizes a belatacept-based regimen coupled with an 11-month tacrolimus overlap period, mycophenolate (MMF), and prednisone. We assessed BK viremia clearance using different IS reduction strategies in patients on a belatacept-based regimen.

Methods: This single-center, retrospective review included kidney transplant recipients on a belatacept-based regimen who developed BK viremia (BK DNA PCR of > 4 log 10 copies/mL) within one-year post-transplant between March 1, 2015 and January 1, 2019. Patients were placed into two cohorts based upon whether MMF or tacrolimus was reduced first after BK viremia diagnosis. BK viremia clearance was defined as BK DNA PCR of < 3 log 10 copies/mL at one year follow up. Secondary outcomes included biopsy confirmed BK virus associated nephropathy (BKVN) or rejection, graft loss with positive BK viremia, and time until viremia clearance. The primary outcome was compared using the Chi-square test and secondary outcomes with either Fischer's Exact test or Student's t-test.

Results: 88 patients were included for analysis: 70 patients with tacrolimus reduction first and 18 patients with MMF. Both groups were similar in demographics. Overall patient age was 51.3 ± 13.1 years at time of transplant and 71.4% (n=50) were African American. Patients developed BK viremia (4.58 ± 0.51 log 10 copies/mL) 121 days (IQR 71.5, 175) post-transplant (p=0.131, p=0.102). There was no statistically significant difference in BK viremia clearance between groups, although the time to viremia clearance was shorter in the MMF group [6 months Vs. 4.5 months (p=0.172)]. The percentage of patients with biopsy proven rejection trended higher in the tacrolimus reduction group [37% Vs. 17%, p=0.159].

Conclusions: Choice of initial IS reduction did not affect BK viremia clearance however more acute rejection with early tacrolimus reduction suggests this may be a suboptimal approach. Additional studies with larger sample sizes may help further elucidate the optimal IS reduction strategy in this population.

Primary and Secondary Outcome Results			
	Tacrolimus first (n=70)	MMF first (n=18)	p-value
BK viremia clearance	54.3% (n=38)	50% (n=9)	p=0.745
Time to clearance (months)	6 (IQR 2.8, 8.8)	4.5 (IQR 4.2, 7.2)	p=0.172
Biopsy confirmed BKVN	24.3% (n=17)	16.7% (n=3)	p=0.753
Biopsy confirmed rejection	37.1% (n=26)	16.7% (n=3)	p=0.159
Graft loss with BK viremia	0% (n=0)	0% (n=0)	p=1

Kidney Immunosuppression

Abstract# 273

A Phase 1 Study to Evaluate the Safety, Tolerability and Pharmacokinetics of At-1501

S. Perrin[1], A. Gill[2], C. Gill[2], P. Gustafson[1], *[1]Novus Therapeutics, Irvine, CA, [2]ALS Therapy Development Institute, Cambridge, MA*

Purpose: Execute a phase 1 study of AT-1501 to assess safety, pharmacokinetics, and functional activity.

Methods: The study employed a placebo-controlled, sequential, dose-escalation design. 28 healthy subjects and 4 adults with ALS were enrolled. Five sequential ascending doses of AT1501 (0.5, 1, 2, 4, or 8 mg/kg) or placebo were administered by IV infusion. The primary endpoint was the safety and tolerability of AT-1501. The secondary endpoint was to determine plasma pharmacokinetics (PK) and anti-drug antibody (ADA) responses to AT-1501. An exploratory endpoint was to examine the ability of AT-1501 to block an immune challenge in subjects who received a Keyhole Limpet Hemocyanin (KLH) challenge.

Results: Dose proportionality was achieved over the AT-1501 dose range of 0.5 to 8 mg/kg for C_{max} and AUC_{0-t}. AT-1501 plasma concentrations decreased over time at all dose levels and were measurable out to 42 days post dose. The mean AT-1501 $t_{1/2}$ in healthy volunteers was 18 to 26 days. The PK parameters in ALS were consistent with those from healthy volunteers at the 1 mg/kg dose level.AT-1501 had a safety profile comparable to placebo and was well tolerated in healthy subjects and subjects with ALS. 54% of subjects treated with AT-1501 had at least 1 TEAE and 62% of subjects treated with placebo had at least 1 TEAE. TEAEs ranged from 33% to 66.7% across groups and did not appear to be dose proportional. No subject had a Grade 2 or higher TEAE. The most commonly reported TEAEs overall were headache, somnolence, and upper respiratory tract infection. There were no meaningful laboratory abnormalities, vital sign assessments, ECG assessments, or physical examination findings.Positive ADA responses to AT-1501 were observed in 6 of 30 subjects in the study. There was no dose dependence with respect to the incidence of positive ADA titers. ADA did not appear to affect AT-1501 plasma PK profiles or parameters suggesting they were not neutralizing.8 mg/kg AT-1501 successfully blocked an immune response to KLH challenge in 2 of the 3 subjects tested.

Conclusions: Our results support further clinical development of AT-1501 for transplantation and autoimmune indications.

Abstract# 274

Evaluation of a Weight-Based Mycophenolate Mofetil Dosing Protocol for Kidney Transplant Maintenance Immunosuppression

M. Mahoney[1], E. Kincaide[1], J. Nelson[1], K. Klein[1], R. Hall[1], S. Bhayana[2], *[1]University Health, San Antonio, Department of Pharmacotherapy and Pharmacy Services, The University of Texas at Austin, Pharmacotherapy Division, College of Pharmacy, San Antonio, TX, [2]University Transplant Center, University Health, San Antonio, Department of Nephrology, The University of Texas Health Science Center at San Antonio, San Antonio, TX*

Purpose: To evaluate the safety and efficacy of a weight-based mycophenolate mofetil (MMF) dosing protocol in adult kidney transplant recipients (KTR).

Methods: This single-center retrospective study of adult KTR compared biopsy proven acute rejection (BPAR), any infections, hospitalizations, granulocyte colony-stimulating factor (G-CSF) use, and MMF dose changes within one year of transplant pre- and post-implementation of a weight-based MMF dosing protocol. Adult patients who received a kidney transplant at University Transplant Center between 12/15/16 and 12/1/19 were reviewed for inclusion. Patients in the weight-based MMF group received 1000 mg twice daily by first clinic visit if ≥ 80 kg, 750 mg twice daily if 50-79 kg, and 500 mg twice daily if < 50 kg. Patients in the fixed-dose MMF group received MMF 1000 mg twice daily. Goal tacrolimus trough was 8-12 ng/mL and prednisone was tapered to 5 mg PO daily by POD5.

Patients who received basiliximab induction immunosuppression, previous renal transplant, experienced delayed or slow graft function (defined by 24-hour urine output ≤500 mL by post-operative day 2), or were African American were excluded.

Results: A total of 140 KTR (51% ≥ 80 kg, 45% 50-79 kg, 4% <50 kg) were included. Baseline characteristics were similar between groups. The majority of patients were middle-aged (median 50 years) Hispanic (62%) males (63%) and received rabbit anti-thymocyte globulin (57%). BPAR and infection rates were similar between both groups. The weight-based MMF group had fewer hospitalizations associated with non-infectious nausea, vomiting, or diarrhea (2.9% vs 12.9%; p = 0.03). Additional outcomes at 1 year are presented in Table 1.

Conclusions: Weight-based MMF dosing was associated with fewer hospitalizations related to non-infectious GI adverse events compared to fixed-dose MMF. BAPR rates and other MMF-related adverse events assessed were similar between groups. Weight-based MMF dosing in standard immunologic risk adult KTR results in similar rates of BPAR and significantly fewer hospitalizations for non-infectious GI adverse events.

Table 1: Rates of Identified Outcomes at 1 Year

	Fixed-Dose MMF n (%) (n=70)	Weight-Based MMF Dose, n (%) (n=70)	p-value
BPAR	8 (11.4)	10 (14.3)	0.80
Any Infection	57 (81.4)	61 (87.1)	0.49
G-CSF use	19 (27.1)	13 (18.6)	0.31
MMF dose change	61 (87.1)	55 (78.6)	0.26
Hospitalization associated with neutropenia	3 (4.3)	2 (2.9)	1
Hospitalization associated with any infection	26 (37.1)	27 (38.9)	1
Hospitalization associated with nausea, vomiting, or diarrhea	9 (12.9)	2 (2.9)	**0.03**

Abstract# 275

The Clinical Validation of a Dried Blood Spot Method for Simultaneous Tacrolimus and Creatinine Measurement

M. I. Francke[1], S. Bouarfa[2], B. van Domburg[2], D. van de Velde[2], M. E. Hellemons[3], O. C. Manintveld[4], S. M. Last-Koopmans[5], M. B. Mulder[2], D. A. Hesselink[1], B. C. de Winter[2], *[1]Internal medicine, nephrology and transplantation, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [2]Hospital Pharmacy, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [3]Pulmonary medicine, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [4]Cardiology, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [5]Hematology, Erasmus MC, University Medical Center, Rotterdam, Netherlands*

Purpose: Monitoring tacrolimus concentrations and kidney function after transplantation is important to avoid tacrolimus under- and overexposure and its clinical consequences, including acute nephrotoxicity. Using dried blood spot (DBS) instead of a venipuncture for blood sampling has several advantages: it allows blood sampling at home and it makes it easier to draw blood samples at a specific or at multiple time points (e.g. for an AUC measurement).

Methods: In this study, a DBS sampling method for tacrolimus and creatinine concentration measurement in blood was clinically validated, by comparing pre-dose whole-blood and serum concentrations (for tacrolimus and creatinine, respectively) obtained by a venipuncture to concentrations measured via DBS. The need for a DBS correction factor and hematocrit correction using near infrared spectroscopy was evaluated. Deming regression was used for validation and potential bias was evaluated with a Bland-Altman analysis.

Results: A total of 50 solid organ transplant recipients was included in the analysis. We calculated the following conversion formula for tacrolimus: $[\text{Tacrolimus}]_{DBS}+1.49)/1.788$, with a Deming intercept of 0.272 (95%-CI -0.53 to 1.08) and a slope of 0.960 (95%-CI 0.84 to 1.07). Using this conversion formula, 92% of the tacrolimus measurements were within the 20% limits of agreement (LOA) and 76% of the tacrolimus measurements were within the 15% LOA (Figure 1). We calculated the following conversion formula for creatinine: $[\text{Creatinine}]_{DBS}+0.8069)/0.9077$, with a Deming intercept of -0.5261 (95%-CI -12.73 to 11.68) and a slope of 1.004 (95% CI 0.92 to 1.08), respectively. Using this conversion formula, 94% of the creatinine measurements were within the 15% LOA. For both tacrolimus and creatinine, no additional correction for hematocrit was required.

Conclusions: DBS sampling was clinically validated and can be used in clinical practice for simultaneous measurement of tacrolimus and creatinine with the use of a conversion formula. An additional correction for hematocrit was not required.

Abstract# 276

CD40 Blockade by the Fc-Silent Immunosuppressive Antibody Iscalimab Results in Diminished B Cell Activation and Differentiation and is Paralleled by Whole Blood Gene Expression Data

R. Kraaijeveld[1], M. W. van den Hoogen[1], A. E. de Weerd[1], E. Ferroro[2], G. Robert[2], U. Laessing[2], B. Haraldsson[2], J. S. Rush[2], C. C. Baan[1], *[1]Erasmus MC, Rotterdam, Netherlands, [2]Novartis Pharmaceuticals AG, Basel, Switzerland*

Purpose: Blockade of costimulatory molecule CD40 by the Fc-silent immunosuppressive drug Iscalimab has shown to inhibit acute alloreactivity in non-human primates and is currently being investigated for prevention of rejection in a CNI-free regimen in transplant patients. Interaction of CD40 on B cells with its ligand on T cells serves as the co-stimulatory factor for B cell activation, proliferation and differentiation, and we were interested in exploring how Iscalimab affected B cell activation in the context of kidney transplantation.

Methods: We measured the number and composition of B cells in kidney transplant recipients who enrolled into the CFZ533X2201 study in the first year after transplantation. Recipients received Iscalimab (n=3) or tacrolimus (n=3) in combination with mycophenolate mofetil and steroids. Additionally, we examined the functional effects of Iscalimab on B cell functions from healthy donors. We also performed RNA-seq profiling of blood samples from CFZ533X2201 collected at baseline before transplant and nine and forty-one weeks post-transplant.

Results: Serial flow cytometric monitoring of samples from Iscalimab-treated patients demonstrated that this agent does not affect the numbers of circulating B cells. In these 3 subjects a complete saturation was found of the CD40-Iscalimab epitope, while a different epitope (HB14) of CD40 was detectable. CD40 occupancy by Iscalimab lead to a 2-fold decrease in memory B cells in the Iscalimab group: 15-26% (range) vs range: 34-65% (range) tacrolimus group. To investigate the effect of CD40 blockade on B cell functions, co-cultures of alloantigen-stimulated B cells with induced follicular T helper cells in the presence of Iscalimab were performed. Proliferation of these allo-activated B cells and their subsequent differentiation towards memory class switched B cells and plasma blasts was significantly inhibited. Activation of these B cells was also inhibited, as shown by the diminished expression of co-stimulatory molecules CD86 and CD40-(HB14). At the transcriptomic level, analyses of biological pathways in whole blood RNAseq data showed evidence of reduced B cell activation in Iscalimab treated patients in comparison to allograft recipients on tacrolimus.

Conclusions: Our sub-study shows that blockade of the Iscalimab-specific CD40 epitope inhibits T cell dependent B cell activation resulting in reduced B cell differentiation *in vitro* and *in vivo* after kidney transplantation. These results were consistent with reduction in a transcriptomic signature associated with B cell activation in patients treated with Iscalimab but not tacrolimus. Collectively our results suggests that one of the mechanisms of action of Iscalimab in kidney transplantation is suppression of B cell activation.

Abstract# 277

Conversion to Belatacept Based Immunosuppression Regimen in Kidney Transplant Patients: Lessons Learned

R. Saidi, N. Huang, C. Yang, I. Movileanu, K. Ecal, A. Senay, O. Pankewycz, R. Dvorai, R. Shahbazov, M. Laftavi, *SUNY Upstate, Syracuse, NY*

Purpose: The costimulatory inhibitor, belatacept (Bela) has been shown to be an effective alternative in several clinical situations including calcineurin toxicity, de novo alloantibody formation and thrombotic microscopic angiopathy. In order to further explore the usefulness of Bela under various clinical scenarios, we performed a retrospective analysis of a prospective database of all recipients who were converted to betatacept maintenance immunosuppression regimen after kidney transplantation.

Methods: This single center study reviewed the electronic records of all patients who received a KT between 2016 and 2020. A total of 57 patients were converted to Bela. Of these recipients, 25 (43.8%) converted within the first 6 months and 32 (56.2%) converted after 6 months. The indications for conversion were: calcineurin inhibitor (CNI) toxicity (26.3%), thrombotic microangiopathy (8.8%), de novo DSA (36.8%), chronic antibody rejection (AMR) with or without significant fibrosis (IFTA) (28.1%).

Results: Early conversion significantly improved GFR at 3, 6- and 12-months post-conversion. However, late conversion has no effect on GFR . Thirty four (59.63%) patients were converted Bela, mycophenolate and steroids and 23 (40.4%) converted to Bela, low dose CNI and steroids. Only 6 patients (10.5%) developed rejection after conversion, 5 (83.4%) in early conversion group. Five patients (83.4%) had T cell mediated cellular rejection and one patient (16.6%) had acute antibody mediated rejection. The rejection rate was 14.7% in group of belatacept without CNI compared to 4.3% in the group on belatacept with low dose CNI ($p<0.001$). All patients with chronic AMR±IFTA were in late conversion group (59.2%) which led to stabilization in their GFR (32 vs 30 mL/min) at 1 year post conversion. Out of 21 patients who were converted to belatacept due to de-novoDSA, 9 (42.9%) patients had complete or partial resolution of DSA. Interestingly, in early conversion group 80% responded vs (31.2%) in late conversion group ($P<0.001$)

Conclusions: The conversion to belatacept was effective, especially when performed early after kidney transplantation. Late conversion to belatacept was beneficiary for a subgroup of patients with chronic changes.

Abstract# 278

Immunosuppression and Cancer Risk in Kidney Transplant Recipients: A Retrospective Cohort Study

R. Sapir-Pichhadze[1], C. Laprise[1], X. Zhang[1], M. Abrahamowicz[1], M. Beauchamp[2], A. Della Vecchia[1], L. Azoulay[1], E. Franco[1], B. Nicolau[1], *[1]McGill University, Montreal, QC, Canada, [2]McGill University Health Centre, Montreal, QC, Canada*

Purpose: Kidney transplant recipients (KTR) have an elevated risk of cancer. We sought to estimate to what extent does the immunosuppression regimen increase KTRs' susceptibility to cancer, and if this risk is modified by age and sex.

Methods: We reconstructed a retrospective 20-year Quebec province-wide cohort including first time kidney only transplant recipients by linking two provincial administrative healthcare databases. Immunosuppression prescription data (date, form, dose, and duration) along with pertinent effect modifiers and confounders were obtained from the *Régie de l'assurance maladie du Québec*. Incident cancer cases were identified in Quebec's clinical and administrative database (Med-ECHO) using the World Health Organization International Disease Classification ICD-10 codes. We computed hazard ratios and 95% confidence intervals [HR (95%CI)] for the associations between risk of cancer and time-varying unweighted cumulative doses of prednisone, MMF and tacrolimus administered over the last 8 years. Exposure to immunosuppression agents was lagged by 2 years as very recent exposure is unlikely to affect the immediate risk of cancer. In addition, we assessed the recency-Weighted Cumulative Exposure (WCE) for the same immunosuppression agents in multivariable models adjusted for sex, age at transplant, era, and the unweighted cumulative doses of the other two immunosuppression agents. Interactions between the main exposures and age, using a 50-year threshold, and sex, were also assessed.

Results: A total of 3,112 KTR experienced 423 cancer events. Cumulative prednisone dose (5mg per day over 8 years, the median follow-up) was associated with an increased risk of cancer [HR 1.28 (95% CI, 1.01-1.64)] while MMF (1000mg per day over 8-years) and tacrolimus (2mg per day over 8-years) were not [0.94 (0.74-1.21) and 0.96 (0.82-1.12), respectively]. We observed a significant interaction between cumulative prednisone dose and age ($p<0.01$), with a higher risk of cancer observed among recipients >50 years of age [1.51 (1.15-1.97)]. We also observed a statistically significant interaction between the cumulative dose of MMF and age ($p=0.03$) with patients ≤50 years experiencing a lower risk [0.67 (0.44-1.01)]. No significant interaction was observed between the cumulative dose of tacrolimus and age or between the cumulative dose of prednisone, MMF or tacrolimus and sex. A similar trend was observed in WCE models for prednisone, MMF and tacrolimus use over an 8-year period vs. non-use with HRs 1.26; 0.91; and 0.95, respectively.

Conclusions: An increased risk of cancer was observed the higher the cumulative dose of prednisone. The cancer risk by cumulative prednisone dose was further accentuated in older KTR. Whether lower intensity regimens may help mitigate risk of cancer warrants further study.

Abstract# 279

Clinical Outcomes Associated with Induction Therapy Regimens for Kidney Transplantation in Children: A NAPRTCS and PHIS Collaborative Report

H. Pizzo[1], D. Levy Erez[2], N. M. Rodig[3], T. Richardson[4], M. Somers[3], *[1]Pediatric Nephrology, Cedars-Sinai Medical Center, Los Angeles, CA, [2]Nephrology Institute, Schneider Children's Medical Center, Tel Aviv, Israel, [3]Nephrology, Boston Children's Hospital, Boston, MA, [4]Children's Hospital Association, Lenexa, KS*

Purpose: Choice of induction agent at the time of pediatric kidney transplant (KTx) is often based upon patient characteristics and center practice. There are limited large scale comparisons of induction agents used for pediatric KTx. We evaluated clinical outcomes and costs based on induction therapy among children in the North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS) registry and the Pediatric Health Information System (PHIS) database.

Methods: Retrospective study of merged data from the NAPRTCS registry and PHIS database between 1999-2019. Participants were grouped by induction agent: no induction, IL2 RB only, rATG/ALG, alemtuzumab. Unadjusted outcomes included graft failure, estimated GFR (eGFR) at 1, 3, and 5-year post-KTx and index hospitalization cost (IHC). Subgroup analysis evaluated graft failure and eGFR at 1, 3, and 5-year post-KTx for deceased donor kidney transplant (DDKT) vs. living donor kidney transplant (LDKT) between 2009-2019. Categorical outcomes were compared across induction therapy groups using a chi-square test for association; continuous variables were compared using a Kruskal-Wallis test.

Results: 2410 KTx with data in both NAPRTCS and PHIS were included in the analysis. 340 subjects (14.1%) received no induction, 960 (39.8%) received IL2 RB only, 943 (39.1%) received rATG/ALG (164 of these also received IL2 RB), and 176 (7.3%) received alemtuzumab. Table 1 highlights the graft failure rate, eGFR, and IHC for those transplanted between 1999-2019. Subset analysis of graft failure and eGFR in those who received DDKT vs. LDKT between 2009-2019 are shown in Table 2 (3.8% no induction, 30.9% IL2 RB, 49.8% rATG/ALG, 15.5% alemtuzumab).

Conclusions: Over the last two decades IL2 RB and rATG/ALG are the more frequently used induction agents at the time of pediatric KTx, however, there is no difference in graft survival at 1, 3, and 5-years post-KTx based on the induction agent used. Alemtuzumab appears to be associated with higher eGFR at the same time points and appears to be associated with lower IHC. Among DDKT performed between 2009-2019, it appears those without induction had higher rates of graft failure, while eGFR was similar among the induction groups at all three time points. Among LDKT, graft failure was similar but recipients with alemtuzumab induction had higher eGFR across all time points.

Abstract# 280

Single-Dose Basiliximab Induction Therapy in Low-Immunologic Risk Kidney Transplant Recipients

A. Hutchins, J. Schoen, J. S. McMullen, *Pharmacy, Nebraska Medicine, Omaha, NE*

Purpose: The purpose of this study is to examine the outcomes associated with single-dose basiliximab in low-immunologic risk kidney transplant recipients following a revision to the kidney transplant induction protocol at our institution.

Methods: A retrospective, single-center, observational chart review was conducted on kidney transplant recipients ≥19 years old who received single-dose basiliximab induction therapy from June 2019 to May 2020 based on the institution's kidney transplant induction protocol (Table 1). All patients received a standard initial steroid taper and three-drug maintenance immunosuppression with tacrolimus, mycophenolate, and prednisone. Patients were excluded if they received lytic induction after receiving basiliximab or experienced graft loss prior to POD4. Patients who received single-dose basiliximab were assessed for incidence of biopsy proven acute cellular rejection (BPAR), antibody mediated rejection (AMR), graft loss, death, BK viremia, and cytomegalovirus (CMV) infection. Data on outcomes were collected for at least 6 months up to 12 months following transplantation.

Results: There were 57 patients who received single-dose basiliximab during the review period. The incidence of BPAR was 3.5% with one patient experiencing Banff Grade III rejection resulting in graft loss. The incidence of AMR was 1.7% with one patient experiencing graft loss. Overall graft survival at the end of the study period was 96.5% and patient survival was 100%. CMV infection was observed in 24.5% of patients and 22.8% of patients had BK viremia.

Conclusions: In this retrospective review, we observed low rates of BPAR, AMR, graft loss, and death in our low immunologic-risk kidney transplant recipients who

received single-dose basiliximab for induction therapy. Single-dose basiliximab appears to be a safe and effective induction therapy regimen in appropriately selected low-immunologic risk kidney transplant recipients. Further study is needed to confirm the findings in this descriptive review.

Disparities in Access and Outcomes in Kidney Transplantation

Abstract# 281

Initial Kidney Transplant Evaluations with Telehealth: Is it a Pandemic Only Practice?

A. Govil[1], E. Tims[2], C. Siemer[2], J. Harris[2], C. King[2], S. Shah[1], C. Thakar[1], *[1]Univ of Cincinnati, Cincinnati, OH, [2]UC Health, Cincinnati, OH*

Purpose: COVID -19 pandemic presented an unprecedented challenge to health care systems. It disrupted the transplant processes including evaluations, especially in rural or other geographically challenged areas in terms of access to transplant care (outreach locations). Prompt utilization of telehealth may change how healthcare is delivered beyond pandemic.

Methods: By April 2020, the healthcare disruption by the pandemic was evident; COVID-19 lockdowns were in full swing with a nationwide shortage of personal protective equipment, most staff working remotely, no in-person clinics, and all evaluation testing/elective surgeries on hold. We promptly converted all our transplant outreach clinics to telehealth based in April. The goal was to continue to connect, communicate, consent, educate, and evaluate our transplant referrals.

Results: The telehealth platform provided safe care for the patients and providers (minimal physical exposure) with the least intrusive means of evaluation. Patients and their families were more open to communicating. It lessened the patient's initial commitment burden towards a visit to the center and helped with their time off from work, transportation, opportunity costs, and provided easy access to health care from their home with almost zero no-show rate. We were able to filter an increasing number of referrals to identify the need for support plans/transportation/weight issues/living donor education at a much earlier stage and continued to move patients through the transplant evaluation process. The challenges noted were: 1) Patient barriers which included access to technology adeptness, system issues, ability to seek technical support, or asking for help. 2) Healthcare system & Provider barriers included a steep learning curve, lack of physical exam/assessment, time-consuming process, missing "personal rapport", lack of state licensure reciprocity across state lines, lower reimbursements/ work credits, and high technology costs. Figures 1 and 2 show trends in referrals, listings, and transplants in 2019 and 2020; despite the challenges in the pandemic, telehealth was able to achieve an increase in all activities in outreach locations.

Conclusions: Pandemic and beyond, telehealth could be a viable standard option for increasing transplant referrals, screening, and initial evaluation. It adds value to transplant outreach clinics and increases patients' access to transplant centers. Licensure reciprocity, improvement in reimbursements, and utilizing more patient-centric platforms are needed to make such models sustainable.

Abstract# 282

Low Socio-economic Status is Associated with Lower Kidney Graft Survival and Increased Risk of Graft Failure Due to Acute Rejection

W. Xie[1], G. Vrakas[1], S. H. Gray[1], A. Haririan[2], J. R. Scalea[1], J. S. Bromberg[1], D. G. Maluf[1], R. P. Meier[1], *[1]Department of Surgery, University of Maryland School of Medicine, Baltimore, MD, [2]Department of Medicine, University of Maryland School of Medicine, Baltimore, MD*

Purpose: Low socio-economic status (SES) has been shown to be associated with poor kidney graft outcomes. We aimed to characterize differences in high and low SES kidney recipients and identify interventions to improve graft survival.

Methods: Kidney transplants performed at the University of Maryland Medical Center between January 1994-June 2020 were evaluated. Income was estimated from recipient's zip code using income tax statistics from the IRS. Primary outcome studied was graft survival. Kaplan-Meier survival analysis, univariate and multivariate Cox regressions were performed.

Results: There were 3131 kidney recipients available for analysis. Income quartile (IQ) cutoff at 25%, 50% and 75% were $48,851, $64,602, and $86,306 USD respectively. Demographics were heterogeneous between IQ except for gender. Recipients in the lowest IQ were more likely to be younger, have higher BMI, have achieved a high school degree at transplant, and self-identified their race as Black. The worst graft survivals were experienced by those in the lowest IQ (Fig 1). Cox regression analysis showed that those in the lower two IQs had a 1.7-fold (95%CI, 1.4-2.1) and 1.4-fold (95%CI, 1.1-1.8) increased risk of graft loss, respectively, compared to those in the highest IQ. Graft failure due to acute rejection was more frequent in the lower IQ. Mixed and Black race were associated with an increased risk of graft loss by 2.9-fold (95%CI, 1.8-4.5) and 2.1-fold (95%CI, 1.9-2.4), respectively, compared to White race. Older recipient age and lower levels of education also negatively impacted graft survival. In multivariate analysis, lower SES, Black race, and older age were all independently associated with poor graft survival.

Conclusions: Low SES negatively impacts kidney graft survival along with race, education and age. Identifying increased rate of graft failure due to acute rejection in low SES groups transforms SES to a modifiable variable. Special attention from

at-risk programs to address systemic barriers to healthcare access, provide close surveillance and improve adherence to immunosuppression must be given to renal transplant recipients with low SES.

Abstract# 283

Geospatial Analysis of Organ Procurement Organizations and Its Impact on Organ Donation Rates

D. Chyou[1], K. Ross-Driscoll[2], R. Lynch[2], D. S. Goldberg[1], *[1]University of Miami, Miami, FL, [2]Emory University School of Medicine, Atlanta, GA*

Purpose: For the majority of organ procurement organizations (OPOs), OPO staff travel to donor hospitals to obtain consent and manage donors, while OPO headquarters (HQ) are the primary site for donor laboratory testing. We hypothesized that donation rates decrease with increased travel time from OPO HQ to donor hospital.
Methods: Retrospective cohort study from 2011-2018 using two data sources: organ donors per hospital per year, aggregated by county, from the Scientific Registry for Transplant Recipients, and potential donors using data from CDC WONDER of inpatient deaths ≤75 years of age from causes consistent with donation (CALC deaths). We aggregated data into two 4-year periods, 2011-2014 and 2015-2018, as these are periods when OPOs underwent review for re-certification by the Center for Medicare and Medicaid Services. OPOs in the contiguous US were included. We used ArcGIS to calculate driving time from the OPO HQ to each county's geographic centroid within the donor service area, accounting for traffic. Counties were aggregated into three bands of driving time (≤30, 31-120, and ≥121 minutes). We calculated the donation rate per 100 CALC deaths for each band. Multivariable mixed-effects linear regression models and post-estimation marginal means were used to calculate and compare donation rates adjusted for factors associated with donation rate.
Results: In adjusted mixed-effects linear models, increased driving time from OPO HQ was associated with decreased donation rates (p<0.001). Nationally, there was a stepwise decrease in donation rates between the three travel time bands during both 2011-2014 and 2015-2018 (Fig. 1). The magnitude of the association between driving time and donation rates varied across OPOs. However, all 56 OPOs analyzed in this study had a decrease in donation rate from the ≤30 to 31-120 minute band, and 55 OPOs had a further drop in donation from the 31-120 to ≥121 minute band (Fig. 2).
Conclusions: Nationally and within almost every OPO, donation rate decreases as driving time from OPO HQ increases in a dose-response relationship. This suggests that increased travel time to candidate donor may be a barrier to successful organ recovery.

Figure 1: National adjusted donation rates by period and driving time band

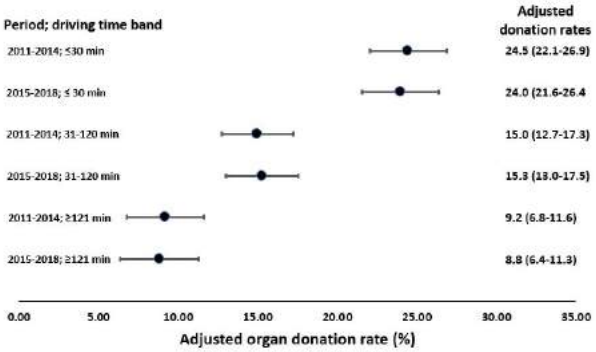

Figure 2: Map of the adjusted donation rates in driving time bands outside of each OPO HQ

Abstract# 284

Obesity is Associated with Greater Gender Disparity in Access to Kidney Transplantation

S. S. Sheikh, B. Orandi, P. MacLennan, H. Qu, R. M. Cannon, D. Anderson, M. Hanaway, S. Mehta, V. Kumar, R. Reed, J. Locke, *Surgery, University of Alabama at Birmingham, Birmingham, AL*

Purpose: Obesity and female gender have been associated with decreased access to kidney transplant. We sought to use contemporary data to examine the likelihood of waitlisting and transplant for obese women with end stage renal disease (ESRD).
Methods: We performed a retrospective cohort study with long-term follow up, using the U.S. Renal Data System, of incident ESRD patients from 2012-2014 who had no contraindication to transplant and were not waitlisted within 90 days at the time of first dialysis service date. We used Cox proportional hazards regression to investigate the likelihood of waitlisting and subsequently transplant for women, stratified by BMI.
Results: We identified 217,320 waitlist-eligible ESRD patients. Of this cohort, men comprised 58.3% and women 41.7%. Women were found to be less likely to be placed on the wait-list compared to men across all BMI categories>18.5 kg/m^2, with the disparity growing more pronounced at higher BMI; BMI 18.5-34.9 aHR 0.86 (95%CI 0.84-0.88), BMI 35.0-39.9 aHR 0.71 (95%CI 0.67-0.75), BMI 40.0-44.9 aHR 0.68 (95%CI 0.62-0.75), BMI 45+ aHR 0.55 (95%CI 0.48-0.62). Once wait-listed, the likelihood for achieving transplantation was not significantly different between genders across the BMI categories; BMI 18.5-34.9 aHR 1.07 (95%CI 1.03-1.11), BMI 35.0-39.9 aHR 0.94 (95%CI 0.85-1.05), BMI 40.0-44.9 aHR 1.11 (95%CI 0.95-1.3), BMI 45+ aHR 1.07 (95%CI 0.86-1.33).
Conclusions: Women, especially with obesity, are less likely to be placed on the deceased donor kidney transplant waitlist compared to men. However, once

waitlisted, the opportunity for subsequent transplant appears comparable to men of the same BMI category. Further research should focus on identification of barriers to referral and evaluation of obese, female patients with ESRD.

Table 1:

Characteristics of waitlist-eligible end-stage renal disease patients (n=217,320) by Sex			
	Men (n=126,744) 58.3%	Women (n=90,576) 41.7%	p-value[1]

Abstract# 285

Age and Racial Disparities in Access to Re-kidney Transplantation

S. S. Patole[1], J. Ahn[1], S. Sandal[2], D. Segev[1], M. McAdams Demarco[3], *[1]Department of Transplantation Surgery, Johns Hopkins School of Medicine, Baltimore, MD, [2]McGill University, Montreal, QC, Canada, [3]Department of Epidemiology, Johns Hopkins School of Medicine, Baltimore, MD*

Purpose: Graft failure is likely increasing among kidney transplant (KT) recipients due to improvements in patient survival. While the benefits of re-KT have been well documented, there are likely disparities in access to re-KT; we quantified the trends and disparities in access to re-KT.

Methods: Using USRDS data, we identified 93,014 adult patients whose first KT graft failed between 1995-2017. We examined trends in graft failure over time and outcomes after graft failure by age, sex, and race. We estimated the chance of listing for re-KT, as well as waitlist mortality, and re-KT among those who were listed (n=46,613) by age, sex, and race using the Kaplan Meier method and adjusted Cox proportional hazards models.

Results: The number of graft failures increased from 2,320 in 1995 to 4,988 in 2017. There were substantial increases in the proportion of older (≥65 years) patients with graft failure; 5.7% in 1995 to 27.5% in 2017. The proportion of Black patients remained steady among those with graft failure, 33.5% in 1995 and 31.3% in 2017, while the proportion of women was 41.1% in 1995 and 39.9% in 2017. The chance of listing for re-KT was lower among older patients (adjusted hazard ratio [aHR]=0.37, 95% CI: 0.36-0.39) and Black patients (aHR=0.79, 95% CI: 0.77-0.81). Only, older patients had a higher risk of waitlist mortality (aHR=2.59, 95% CI: 2.40-2.79). Older patients (aHR=0.92, 95% CI: 0.85-0.99) and Black patients (aHR=0.53, 95% CI: 0.50-0.55) were less likely to receive re-KT. There were no differences in listing, waitlist mortality, or KT by sex.

Conclusions: There are age and racial disparities in access to re-KT. Efforts should be made to improve equitable access to re-KT for older and Black patient with graft failure.

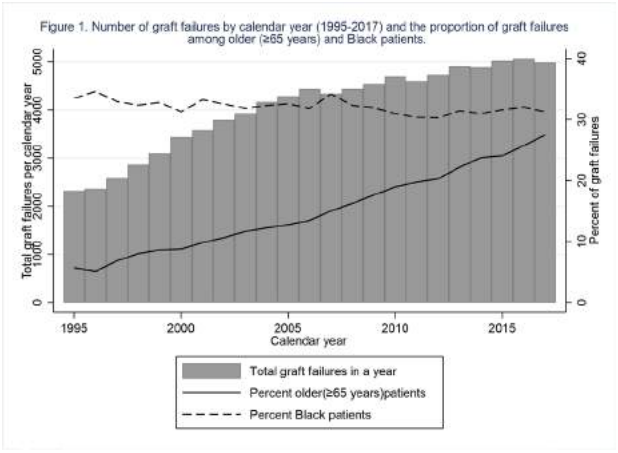

Table 1. Outcomes after kidney transplant graft failure (1995-2017) by age, sex, and race (n=93,014). Mortality and re-transplantation study populations were restricted to patients who were listed after graft failure (n=46,613). All Cox proportional hazard models were adjusted for age, sex and race. Disparities in access to KT were by age and race were observed; there were no disparities by sex.

	Listing (n=93,014) aHR (95% CI)	Mortality (n=46,613) aHR (95% CI)	Re-transplantation (n=46,613) aHR (95% CI)

Abstract# 286

Impact of a Latinx Kidney Transplant Clinic

P. Serrano Rodriguez, *Abdominal Transplant Surgery, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Purpose: To evaluate the impact of a Latinx clinic in our institution. With a growing increase of end stage renal disease (ESRD)in the Latino population we opened a clinic with a focus on providing care to Latino patients and their families. The clinic addresses commonly shared cultural values, beliefs, and misconceptions of this population while simultaneously providing information to meet the clinical needs of ESRD patients along with education and recruitment of potential living kidney donors in order to improve Latino access to transplant-related healthcare. The clinic is staffed by a Spanish speaking team of a nurse coordinator, an administrative assistant/scheduler, a financial advisor, and a transplant surgeon. Interpreters are also present to facilitate communication between the rest of the staff and non-English speaking patients.

Methods: This is a retrospective chart review study to evaluate waitlist data from our own institution. We compared the number of Hispanic/Latino patients in our institution the year prior to opening the Latinx clinic and the year after. Interaction terms and Wald Chi-square tests were used to estimate differences in transplant rate. In all data sources, race/ethnicity was self-reported.

Results: Comparing the number of patients in 2018 prior to the inclusion of the Latinx Clinic to the same group in 2019. The first year after its opening, there was a 125% increase in the number of Latinx referrals for kidney transplant evaluation (28 in 2018 vs 63 in 2019) and a 142% increase in the number of waitlisted Latinx patients (12 in 2018 vs 29 in 2019), there was an increase in kidney transplants of 145% (11 in 2018 vs 27 in 2019). The number of living donor kidney transplants (LDKT) in Latinx patients increased from 1 in 2018 to 4 in 2019.

Conclusions: With the increasing number of patients in the Latino community who are diagnosed with ESRD, there is a direct benefit for a culturally competent program that addresses access to transplantation.

Abstract# 287

Disparities in Access to Listing in Rural Populations Post-KAS Implementation

S. H. Nguyen[1], R. R. Redfield[2], N. Neidlinger[1], D. P. Foley[1], D. B. Kaufman[1], J. T. Adler[3], *[1]Department of Surgery, University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]Department of Surgery, University of Pennsylvania, Philadelphia, PA, [3]Department of Surgery, Brigham and Women's Hospital, Boston, MA*

Purpose: One major goal of the Kidney Allocation System (KAS) was to improve access to transplantation. The impact of KAS on rural populations has been poorly studied; here we assess access to the waitlist for rural populations compared to their urban counterparts.

Methods: Using the Scientific Registry of Transplant Recipients, we assessed changes in demographics of rural and urban patients listed pre-KAS (2010-2013) and post-KAS (2015-2018). Rurality was determined by candidate home address with Rural-Urban Commuting Area Codes. Access to transplant, measured via waitlist composition, being listed pre-dialysis, and dialysis time at registration, was analyzed using multiple regression.

Results: Overall, listings increased by 5,966 patients under KAS. Although rural patients make up 24.3% of the total waitlist registrant cohort, only 12.5% (n=746) of increased listings post-KAS were rural, suggesting they had less benefit from KAS than urban patients (P<0.001, Table). Adjusting for patient demographics, comorbidities, and organ procurement organization (OPO), post-KAS new listings were less likely to be from rural areas than pre-KAS (OR 0.97 [0.94-0.98], P<0.001). 5 OPOs increased rural registrants while 2 decreased (P<0.05, Figure) after KAS. Post-KAS status was associated with a slight increase in days on dialysis (95.3±5.2 days, P<0.001) and being listed preemptively (OR 1.51 [1.47-1.54], P<0.001), but neither were related to rural status (P=0.95).

Conclusions: Although KAS increased overall access to listing by increasing waitlist registration and preemptive listing, it generally disfavors rural versus urban populations. Further efforts are needed to evaluate causes of these disparities and the downstream effects on transplantation.

Table: Demographics

	Pre-KAS (n=106,451)	Post-KAS (n=112,417)	Total (n=218,868)
Population			
Urban	80209 (75.3%)	85429 (76%)	165638 (75.7%)
Rural	26242 (24.7%)	26988 (24%)	53230 (24.3%)
Age at listing (years)	52.6 (18-88)	52.9 (18-89)	52.8 (18-89)
Sex			
Male	65130 (61.2%)	70104 (62.4%)	135234 (61.8%)
Female	41321 (38.8%)	42313 (37.6%)	83634 (38.2%)
Race

Abstract# 288

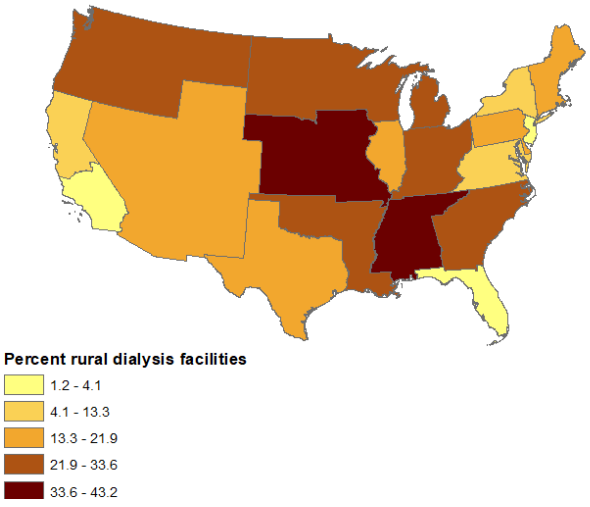
Rural Dialysis Facilities are Associated with Better Dialysis Quality but Less Home Dialysis Use

J. T. Adler[1], L. Xiang[1], S. S. Waikar[2], *[1]Surgery, Brigham and Women's Hospital, Boston, MA, [2]Medicine, Boston Medical Center, Boston, MA*

Purpose: Dialysis facility quality is associated with patient outcomes. The 60 million rural dwellers across the United States are older, more likely to live in poverty, and more likely to be either underinsured or uninsured compared to their urban counterparts. 240,000 of these rural dwellers have ESKD; it is unknown if differences in dialysis facility size and quality exist between urban and rural settings.

Methods: Using the 2017 United States Renal Data System Facility File and Medicare Dialysis Facility Compare, we identified 1,472 (19.7%) rural and 6,008 (80.3%) urban dialysis facilities as classified by Rural Urban Commuting Area codes. Differences in characteristics, resources, and patient outcomes were assessed between rural and urban facilities.

Results: There was significant variability in the proportion of rural dialysis facilities across the ESRD Networks (Figure, P<0.001). Rural dialysis facilities were more likely to be non-profit (19.7 vs. 11.9%, P<0.001). Rural facilities were smaller (median dialysis stations 13 vs. 18, P<0.001), but had more support staff: fewer patients per social worker (41 vs 65, P<0.001) and patients per nurse (12 vs. 15, P<0.001). Rural facilities had fewer patients on home dialysis (median 7.4 vs 13.7%, P<0.001). In terms of quality metrics, there was no association with mean standardized mortality (1.01 vs. 1.02, P=0.08) or transfusion ratios (1.02 vs. 1.00, P=0.18), but the mean standardized hospitalization ratio (0.86 vs. 1.04, P<0.001) and 90-day catheter infection rates (10.2 vs. 10.6%, P=0.01) were lower for rural facilities.



Conclusions: Facility size and quality metrics vary among rural and urban dialysis facilities. Rural facilities had more staffing resources and better ESKD quality

metrics, but surprisingly had fewer patients on home dialysis. Further work is needed to assess impact of dialysis facility quality on long-term rural ESKD outcomes, as well as to improve the number of patients on home dialysis.

Liver

Liver Pediatrics

Abstract# 289

Pediatric Donation During COVID-19 Pandemic

M. MacConmara, B. Wang, L. de Gregorio, J. Shah, D. Desai, S. Hanish, P. Vagefi, C. S. Hwang, *Surgery, UT Southwestern Medical Center, Dallas, TX*

Purpose: The COVID-19 pandemic led to a decrease in transplantation throughout the United States. We examined the impact of the pandemic in regards to the volume of pediatric donors from which livers were successfully transplanted and donor characteristics during this time.

Methods: The UNOS database was examined between 3/1/2019 - 8/1/2019 (non-COVID era) and 3/1/2020 - 8/1/2020 (COVID era). The numbers of potential pediatric donors and those who donated livers were determined. Donor demographic data was obtained. STATA software was used to perform statistical analysis. A p-value of <0.05 was considered to be significant.

Results: There was a 12% decrease in referral numbers of pediatric liver donors between the non-COVID period (n=440) and the COVID period (n=389). Additionally, overall (25% vs. 27%) and intraoperative (10% vs. 11%) discard rates were higher resulting in a 14% reduction in livers for transplant between non-COVID and COVID periods. Patterns were not uniform across the country. Region 5 had an increase in donors from the non-COVID to COVID era (6.25%), while region 10 had the greatest decrease in donors (15%). Analysis of donor data did not show differences in age (10.9 vs. 11.1 y), BMI (21.7 vs. 21.2 kg/m^2), AST (94 vs. 101 U/L), ALT (107 vs. 84 U/L), whole organ use (94.7% vs. 96.7%), DCD status (7.8% vs. 7.3%), or IRD status (14.8% vs. 13.0%) between COVID and non-COVID periods. Macrosteatosis (3.7% vs. 12.6%) was lower in the COVID period although few livers underwent biopsy. Interestingly, the DRI was significantly higher in the COVID period (1.77 vs. 1.60, p = 0.001) with a greater proportion of higher risk donors (DRI>2) used during COVID (24%) compared to non-COVID (20%).

Conclusions: During the COVID period there was a large decrease in pediatric donor referral. It appears that this promoted utilization of livers with higher overall donor risk by liver transplant centers.

Abstract# 290

The Pediatric National Liver Review Board: What Happens to Waitlist Registrations with Denied Exception Forms?

J. Foutz[1], C. Martinez[1], A. Henderson[1], E. K. Hsu[2], E. R. Perito[3], J. Heimbach[4], *[1]United Network for Organ Sharing, Richmond, VA, [2]Seattle Children's Hospital, Seattle, WA, [3]UCSF, San Francisco, CA, [4]Mayo Clinic, Rochester, MN*

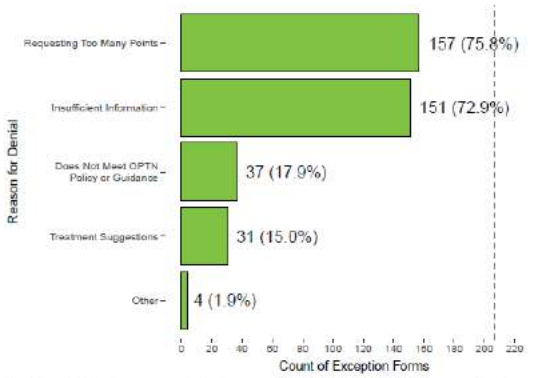
Purpose: On 5/14/19, the exceptions review process for pediatric liver transplant (LT) candidates was changed from 11 Regional Review Boards to one National Pediatric Liver Review Board (NLRB). We categorized reasons for denials for pediatric exceptions submitted to the NLRB and followed waitlist registrations with denied exception forms over time.

Methods: Reviewer comments for pediatric liver exception requests submitted to the NLRB 5/14/2019-3/31/2020 and subsequently denied were summarized. Exception requests denied for requesting too many points and/or not submitting enough information were followed from 5/14/2019-7/2/2020 at the waitlist registration level to determine action taken after denial. Consecutive exception narratives were programmatically analyzed using Natural Language Processing.

Results: Since NLRB implementation, 799 pediatric exception forms were submitted; 207 (26%) were denied. Nearly all (97%) were denied for requesting too many exception points and/or not submitting sufficient information (Figure). Of the 128 waitlist registrations that accounted for all 200 of these denied requests, 64 (50%) submitted an appeal, 38 (30%) submitted a new exception request without first submitting an appeal, and 26 (20%) submitted no appeal or new exception. Appeals or ART appeals were often approved (69%, n=44), as well as new cases (84%, n=32). Both appeals and new cases most commonly requested fewer points. In 12 cases no new narrative information was added, 10 of which lowered the amount of points requested. Among the 128 children, 89 (70%) received a transplant, 28 (22%) were still waiting, 3 (2%) were removed for death or too sick, and 8 (6%) were removed for other reasons.

Conclusions: Nearly all denied exception requests to the Pediatric NLRB were denied for requesting too many points and/or not submitting sufficient information. Adding additional guidance for providers submitting to the Pediatric NLRB could improve efficiency and support children's access to LT.

Figure. Denied Exception Forms by Reasons for Denial, Pediatric NLRB (5/14/2019-3/31/2020)



Note: Reasons for denial are not mutually exclusive; each denial can have more than one reason. The denominator used to calculate the percentages in this figure is the 207 denied exception forms submitted to the Pediatric NLRB from May 14, 2019 - March 31, 2020 and is represented by the dashed line.

Abstract# 291

The Confluence of Race, Socioeconomic Deprivation, and Waitlist Mortality for Children Awaiting Liver Transplant

S. Wadhwani[1], J. Ge[1], L. Gottlieb[1], C. Lyles[1], A. F. Beck[2], J. Bucuvalas[3], U. Kotagal[2], J. C. Lai[1], *[1]University of California San Francisco, San Francisco, CA, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Icahn School of Medicine at Mount Sinai, New York, NY*

Purpose: Social determinants like racism, ethnocentrism, and neighborhood socioeconomic deprivation are associated with poor outcomes for children after liver transplant. We studied the relationship between race, ethnicity, and waitlist mortality, and whether this relationship is mediated by neighborhood deprivation.

Methods: We used SRTR data for children<18 yr listed for liver transplant 2005-2015 (N=8536). Primary exposures were race, ethnicity, and a neighborhood socioeconomic deprivation index (NDI) linked to home ZIP codes (range [0,1]; higher values indicate increased deprivation). Primary outcome was waitlist mortality, defined as death or delisting for 'being too sick'. We used competing risk analyses to associate race, ethnicity, NDI, and death with transplant as the competing risk.

Results: There were N=7716 children-17% identified as Black and 24% as Hispanic. Median NDI was 0.38 (IQR 0.30, 0.46). Compared to White children, Black and Hispanic children had higher NDIs. In univariate analysis, Black and Hispanic children had increased hazard of waitlist mortality (sHR: 1.23; 95%CI: 1.01, 1.49 and sHR: 1.28; 95%CI: 1.08, 1.51, respectively). Each 0.1 increase in the NDI was associated with increased hazard of waitlist mortality (sHR: 1.08, 95%CI: 1.01, 1.15). In bivariate analysis combining race and NDI, each 0.1 increase in NDI was associated with increased hazard of waitlist mortality (sHR: 1.08, 95%CI: 1.02, 1.40), however, Black race was no longer significant (sHR: 1.17 95%CI: 0.96, 1.43). In multivariable analysis combining race, NDI, and initial lab PELD/MELD, race and NDI were no longer significant.

In bivariate analysis combining ethnicity and NDI, Hispanicity was associated with increased hazard of waitlist mortality (sHR: 1.22; 95%CI: 1.02, 1.46), however, NDI was no longer significant. In multivariable analysis combining ethnicity, NDI, and initial lab PELD/MELD, Hispanicity remained associated with increased hazard of waitlist mortality (sHR: 1.20; 95%CI: 1.00, 1.43).

Conclusions: Black race is associated with increased waitlist mortality. This risk may be mediated by neighborhood deprivation; which, in turn, may be mediated by disease severity. Hispanic ethnicity conferred increased risk of waitlist mortality after adjusting for deprivation and initial lab PELD/MELD—suggesting that other social determinants (e.g. ethnocentrism) may lead to these disparities.

Abstract# 292

Clinical Value of Surveillance Biopsies in Pediatric Liver Transplantation: A Single Center Experience with >800 Biopsies

B. Rocque[1], A. Zaldana[1], C. Weaver[2], J. Huang[1], A. Barbetta[1], V. Shakhin[2], C. Goldbeck[1], G. Yanni[2], R. Kohli[2], Y. Genyk[1], J. Emamaullee[1], *[1]Surgery, University of Southern California Keck School of Medicine, Los Angeles, CA, [2]Pediatrics, Children's Hospital-Los Angeles, Los Angeles, CA*

Purpose: While pediatric liver transplantation (LT) results in excellent long-term outcomes, a high incidence of early acute cellular rejection (ACR) and late graft fibrosis persists. Routine liver function tests may not reliably detect rejection episodes or identify patients who are candidates for reduced/modified immunosuppression (IS). Surveillance biopsies (SB) can provide valuable information in this regard, but their role in pediatric LT continues to be controversial.

Methods: A retrospective cohort of 232 pediatric LT recipients who underwent biopsy between 2003-2019 was studied to characterize the potential risks and benefits of SB vs 'for cause' biopsies. At our center, SB was performed ≥5 years post-LT with stable graft function or 1-year post biopsy-proven ACR.

Results: Among 816 biopsies obtained from 232 patients, 150 (18%) were SB. Only 6 (0.7%) of patients in the entire cohort had a biopsy-related complication, and none were observed in the SB subset. Liver function tests did not predict rejection severity on biopsy (ALT AUROC 0.65 (very poor prediction), Bilirubin AUROC 0.58 (no prediction), GGT AUROC 0.56 (no prediction)). SB identified a subclinical rejection episode in 18.6% of biopsies. When obtained within 24 months of LT, 7.7% of SB led to changes in IS, when obtained >24 months post-LT 18.7% prompted IS change including reduction. SB obtained <10-years post-LT trended toward higher incidence of ACR (Fig. 1A), with reversal at >10 years, although this was not significant (p=0.24). Graft survival and patient survival did not differ between SB and 'for cause' groups (Fig. 1B and C). 63% of SB had some evidence of fibrosis.

Conclusions: In our experience, SB in pediatric LT have a good safety profile and provide valuable information about subclinical rejection episodes, leading to changes in management of IS. Further multi-center studies are needed to examine the role for SB on long-term outcomes in pediatric LT.

Abstract# 293

Degree of T Cell Infiltration Predicts Treatment Response in Pediatric Liver Late Acute Cellular Rejection

M. Rogers, G. Begum, Q. Sun, A. Peters, *Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Purpose: Late acute cellular rejection (ACR) occurs >6mo post-liver transplant and is associated with chronic rejection and allograft loss. Currently, no diagnostic features predict ACR treatment response. ACR is primarily T cell mediated, yet B cells and plasma cells (PC) also infiltrate the portal areas during late ACR. To test the hypothesis that the inflammatory milieu is associated with delayed response to rejection therapy, we performed a single center retrospective case-control study of pediatric late liver ACR using immunofluorescence for T cell, B cell, and PC markers.

Methods: Pediatric liver-only transplant recipients transplanted at <17 years of age and treated for biopsy-proven late ACR between Jan 2014-Jan 2019 were stratified into rapid responders (RR) and delayed responders (DR) based on ALT normalization <30d (RR) or >30d (DR). All patients received IV methylprednisolone as initial rejection treatment. Anti-thymocyte globulin was used for treatment of steroid-refractory rejections exclusively in the DR category. No rejections led to graft loss. Banff score, medication level variation index (MLVI), and autoantibodies were analyzed for each ACR episode. We performed multiparameter immunofluorescence for CD4, CD8, CD20, and CD138 in FFPE liver biopsy tissue at the time of ACR diagnosis, and used logistic regression to determine if each cell count/hpf was associated with increased risk of DR compared to RR.

Results: 60 liver biopsies in 54 patients were included in the analysis. 33 (55%) were DR, the average age at rejection was 10.8 years, the average time between rejection and transplant was 5.4 years, and the majority were transplanted due to biliary atresia (55%). Only one rejection episode occurred in a patient transplanted for autoimmune hepatitis. Based on univariate logistic regression analysis, treatment response was independent of Banff score and a lower MLVI was associated with decreased risk of DR (Table 1). However, a 10-fold increase in CD8 or CD4 count was associated with 2.9-fold and 2.05-fold the odds of DR compared to RR, respectively. Similarly, presence of ANA and ASMA autoantibodies at titers >1:80 were associated with 9-fold increased risk of DR (OR 9.136)

Conclusions: Increased CD4 and CD8 counts in late ACR portal infiltrates may be early predictors of delayed response to anti-rejection treatment. While a larger sample size is required for validation, these results may point towards the benefit of early use of T-cell directed therapies for late ACR in high risk patients.

Table 1: Risk factors for delayed response to treatment in late liver ACR

Risk Factor	Delayed Response OR	Delayed Response CI
MLVI	0.597	0.346-1.031
CD4	2.053	0.409-10.304
CD8	2.897	0.397-21.142
CD20	1.159	0.391-3.433
CD138	1.069	0.462-2.477
Auto-Antibodies	9.136	0.876-95.288
Banff score	0.953	0.657-1.381

Abstract# 294

Are All DSA's the Same? Are We Ready for Precision Medicine in Pediatric LT?

S. E. Shin[1], M. Lee[1], N. Yazigi[2], K. Khan[2], S. Kaufman[2], J. Ahn[3], O. Timofeeva[4], U. Ekong[2], *[1]Georgetown University School of Medicine, Washington, DC, [2]Medstar Georgetown Transplant Institute, Medstar Georgetown University Hospital, Washington, DC, [3]Biostatistics, Bioinformatics, & Biomathematics, Georgetown University, Washington, DC, [4]Histocompatibility Laboratory, Dept. of Pathology & Laboratory Medicine, Georgetown University, Washington, DC*

Purpose: Donor-specific antibodies (DSA) play an uncertain role in rejection after liver transplantation (LT). We hypothesized that evaluation of epitope differences in HLA-DR/DQ mismatching can improve identification of alloimmune sensitization risk.

Methods: Retrospective review of pediatric LTs performed in our center between January 2003 and November 2019 with at least 1 DSA measurement using Luminex® Single Antigen bead platform (positive cutoff 1000 MFI). HLAMatchmaker™ 3.1 was used to determine the number of mismatched DRB1/DQB1 eplets for each donor-recipient pair. ROC analysis was used to identify optimal cutoff of eplet mismatch load for *de novo* DSA (*dn*DSA). Chi-squared tests and ANOVA were used to compare demographic and clinical parameters including development of *dn*DSA & acute rejection (AR) across the three risk groups. Log-rank tests & Cox proportional were used to evaluate the association between the three risk groups & *dn*DSA-free survival, & AR.

Results: Out of 244 pediatric LT, DSA testing in 172 detected *dn*DSA in 73 (42%). ROC determined an eplet mismatch load of 6 & 2 for antibody-verified DRB1 & DQB1 *dn*DSA (AbDRB / AbDQB), respectively, with AUC of 0.68 & 0.60 respectively. High-risk patients had significant shorter *dn*DSA-free survival vs. low risk patients (log-rank $p < 0.01$) (Figure 1A). There was no significant age, or race difference in *dn*DSA-free survival, and anti-DQ2 did not predominate (Figure

1B). AR frequency was 19%. AR-free survival did not differ between high-risk vs. low-risk patients with Ab-verified *dn*DSA (log-rank p = 0.05) or between DSA pos vs. DSA neg patients.

Conclusions: Mismatched epitope load can predict DSA-free survival in pediatric LT recipients. Although previous reports found that DQ2 *dn*DSA was associated with an increased likelihood of AR, we found no significant association, possibly due in part to low frequency using eplet mismatch methodology.

Abstract# 295

Center Use of Technical Variant Grafts Impacts Pediatric Liver Transplant Waitlist and Recipient Outcomes in the United States

G. Mazariegos[1], E. R. Perito[2], J. Squires[1], K. Soltys[1], A. Griesemer[3], S. A. Taylor[4], E. Pahl[5], *[1]Childrens Hosp of Pittsburgh, Pittsburgh, PA, [2]UCSF, San Francisco, CA, [3]Columbia University Irving Medical Center, New York, NY, [4]Lurie Children's Hospital of Chicago, Chicago, IL, [5]Omnilife, Lexington, KY*

Purpose: Assessing composite outcome measures are critical when evaluating graft type selection in pediatric liver transplantation (LT).

Methods: OPTN data on children listed for first-time LT or liver-kidney transplant from 11/2004- 9/2020 was analyzed and grouped by center code. Centers performing < 10 LT or with < 5 children waitlisted over the study period were excluded. Variance was plotted in terciles spanning the min and max of center metrics: LT volume, waitlist mortality, and rate of technical variants (TV, deceased and living donor), and of graft and recipient death within 1yr post-TX. Center metrics were analyzed for their association with center waitlist mortality and patient survival with univariate linear and Cox proportional hazard regressions.

Results: From 2004-20, 63 centers performed 7563 LT; 935 children died on the waitlist. Waitlist mortality by center ranged from 0-22% (p < .00) and center TX volume, and graft outcomes by terciles are shown in Figure 1. Centers with higher waitlist mortality have significantly lower rates of TV graft use and lower rates of recipient and graft survival for children that reach LT. Survival from waitlisting to death was significantly higher with increased center usage of any TV graft among other center-specific metrics. Rate of TV use varied widely across pediatric LT centers, but overall those with TV usage rates in the lower 50% accounted for the majority of centers with higher waitlist mortality (Figure 2).

Conclusions: Waitlist death rate and TV usage varies dramatically among pediatric LT centers in the US; > 10% of children continue to die awaiting LT. Centers with increased TV graft usage have significantly lower waitlist mortality and higher patient survival. Evaluating graft selection practices of high performing centers can better inform training and center practices and help develop organ graft type decision support tools in pediatric LT.

Abstract# 296

Cost Effectiveness Analysis Comparing Treatments of Biliary Strictures in Pediatric Liver Transplant Patients

B. Whitehead[1], C. Lemoine[2], R. Superina[2], J. Green[3], S. Mohammad[1], *[1]Division of Gastroenterology, Hepatology and Nutrition, Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [2]Division of Transplant Surgery, Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [3]Division of Interventional Radiology, Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL*

Purpose: Biliary strictures are associated with significant morbidity after pediatric liver transplantation. There are two main treatment options which are percutaneous transhepatic cholangiography (PTC) and stent placement or surgical revision. The optimal approach is still debated. We performed a cost effectiveness analysis comparing both therapies.

Methods: We designed a Markov decision analysis model using TreeAgePro to simulate a cohort of patients treated for post liver transplant biliary strictures with 5 years of follow up. Transition probabilities were based on review of published literature on outcomes of pediatric patients with biliary complications. Treatment success was defined as absence of stricture recurrence for 12 months following intervention. Health utilities were estimated based on published literature and expert opinion. Cost variables defined using billing data from our institution. Willingness to

pay (WTP) was set at $100,000/QALY. For each intervention we calculated cost and quality adjusted life years (QALYs), which were used to determine the incremental cost effectiveness ratio (ICER).
Results: Stenting of biliary strictures provided 4.47 QALY over 5 years at a cost of $49,148 compared to surgical revision, which provided 4.56 QALY at the cost of $278,805 with an ICER of $655,500/QALY, which is well above our willingness to pay. Cost effectiveness estimates were most sensitive to changes in cost of surgery, success of stenting and health utility for surgery and stenting. Sensitivity analysis showed stent placement remained cost effective even when stent success rate was as low as 30%.
Conclusions: Both stent placement and surgical revision result in similar QALYs but there are large cost differences. The current approach of treating biliary strictures first with stent placement by interventional radiology is cost effective compared to surgical revision using a WTP of $100,000.

Randomized Phase 3 Open-label Study of Maribavir vs Investigator-assigned Therapy for Refractory/resistant Cytomegalovirus Infection in Transplant Recipients: Subgroup Analyses of Efficacy by Organ

R. K. Avery[1], E. A. Blumberg[2], D. Florescu[3], N. Kamar[4], D. Kumar[5], J. Wu[6], A. Sundberg[6], *[1]Johns Hopkins Hospital, Baltimore, MD, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Nebraska School of Medicine, Omaha, NE, [4]Hôpital de Rangueil, Toulouse, France, [5]University Health Network, Toronto, ON, Canada, [6]Shire Human Genetic Therapies, Inc., a Takeda company, Lexington, KY*

Purpose: Therapeutic options for refractory, with/without resistance (R/R), CMV infections are limited. We report organ type subgroup analyses from a large multicenter trial that studied the efficacy of maribavir (MBV) vs investigator-assigned therapy (IAT) in pts with R/R CMV infection.
Methods: Transplant recipients aged ≥12 yrs, with CMV infection (viral load [VL] ≥2730 IU/mL/≥910 IU/mL CMV DNA [blood/plasma]) refractory to recent Tx (failure to achieve >1 $\log_{10}$ decrease in CMV DNA after ≥14 days) were eligible (NCT02931539). Pts were stratified (HCT/SOT + screening CMV VL) and randomized 2:1 to MBV 400 mg BID or IAT (val/ganciclovir, foscarnet, cidofovir, foscarnet+val/ganciclovir) for 8 wks + 12 wks follow-up. Primary endpoint: confirmed CMV clearance (plasma CMV DNA <137 IU/mL in 2 consecutive tests ≥5 days apart) at end of Wk 8. Key secondary endpoint: CMV clearance and symptom control at end of Wk 8 and maintained through Wk 16. Group differences, adjusted for baseline CMV DNA level <9100/≥9100 IU/mL, and SOT/HCT were compared (Cochran-Mantel-Haenszel tests). Subgroup analyses by SOT type were conducted.
Results: 352 pts were randomized (235 MBV, 117 IAT; age range 19-79 years). Significantly more pts (MBV vs IAT) achieved the primary (55.7% vs 23.9%; difference, 95% CI: 32.8%, 22.8-42.7; p<0.001) and key secondary endpoint (18.7% vs 10.3%; difference, 95% CI: 9.5%, 2.0-16.9; p=0.013). 211 pts (59.9%) were SOT recipients (kidney, 50.2%; lung, 29.4%; heart, 10.9%; liver, 3.3%; pancreas, 0.9%; intestine, 0.5%; multiple, 4.7%). A benefit trend for MBV vs IAT in kidney, lung, and heart transplants was seen (**Fig**). No SOT pts lost grafts. Tx-emergent AEs (TEAEs) with MBV vs IAT (overall % pts): 97.4% and 91.4%. Acute kidney injury with MBV vs foscarnet was lower: 8.5% vs 21.3% (TEAE) and 1.7% vs 19.1% (Tx-related TEAE). Neutropenia with MBV vs val/ganciclovir was lower: 9.4% vs 33.9% (TEAE) and 1.7% vs 25.0% (Tx-related TEAE). Overall, 2 Tx-related serious TEAEs led to death (1 pt per arm).
Conclusions: MBV showed superior efficacy vs IAT in clearing CMV in transplant recipients with R/R CMV infection, with consistent trends across organ types and lower rates of Tx limiting toxicities common with IAT.

Ayares[4], D. Kaczorowski[1], M. Mohiuddin[1], *[1]Surgery, University of Maryland School of Medicine, Baltimore, MD, [2]Department of Medicine, Division of Pulmonary and Critical Care Medicine, University of Maryland School of Medicine, Baltimore, MD, [3]Pediatrics, Pediatric Critical Care Medicine, University of Maryland School of Medicine, Baltimore, MD, [4]Revivicor, Inc., Blacksburg, VA*

Purpose: Cardiac xenotransplantation has been proposed to bridge the gap in organ shortage for those in end-stage heart failure without the opportunity to receive a heart. Recently, it has been shown that survival of a non-human primate recipient with a genetically engineered (GE) porcine- cardiac xenograft can be achieved up to 6 months in the orthotopic position with the addition of temsirolimus, blood pressure and heart rate control. We investigate an alternative means to achieve long-term survival, without the use of these adjuncts. We used "Multi-gene" edited pigs as xenograft donors with the addition of multiple human transgenes for complement regulation, thromboregulation, anti-inflammation and growth.
Methods: Baboons weighing 15-30 kg were used as recipients for life supporting cardiac xenografts. Weight-matched swine with multi-gene constructs were used as donors (table 1). Cardiac preservation was performed using an XVIVO© Perfusion system with XHS blood cardioplegia induction. Recipient blood pressure and heart rate were not controlled and temsirolimus was not administered after transplantation.

Results: Group 1 xenografts functioned well between 84-95 days, but ultimately succumbed to antibody mediated rejection and diastolic heart failure. Group 2 xenografts functioned well over 6 months. One was electively euthanized on post-transplant day #182 for histologic examination. The second recipient underwent an endomyocardial biopsy on post-transplant day #220, with survival ongoing greater than 240 days exhibiting excellent graft function. Both demonstrated normal histology without evidence of rejection.

Conclusions: Xenografts with multiple transgenes and knockouts produce durable long-term survival and demonstrate pre-clinical efficacy to pursue the first human clinical trials. Consideration should be those with CMAHKO and GHRKO.

Abstract# LB 11

Immunologic Endotypes of Ischemia-reperfusion Injury in Human Liver Transplantation

R. A. Sosa, A. Q. Terry, F. M. Kaldas, B. V. Naini, T. Ito, R. W. Busuttil, D. W. Gjertson, J. W. Kupiec-Weglinski, E. F. Reed, *UCLA, Los Angeles, CA*

Purpose: Ischemia-reperfusion injury (IRI) is a major risk factor for allograft rejection in orthotopic liver transplantation (OLT), involving complex interactions between innate and adaptive immune systems. However, no clinical therapeutics or patient-specific diagnostics are currently available. Etiologies leading to OLT are heterogeneous, and only ~50% of OLT recipients experience IRI despite similar immunosuppression regimens. Genetic susceptibility to IRI is unknown, and rates of progression differ markedly, as do post-transplant liver function and patient and allograft outcomes. Therefore, we sought to identify associations between inflammatory endotypes and clinical presentations in OLT-IRI.

Methods: We enrolled 164 OLT recipients in our IRB-approved study. We investigated evolving patient immune status via longitudinal single-antigen bead HLA antibody assay, histopathology and RNAseq of pre- and post-reperfusion biopsies, soluble cytokines, chemokines and growth factors via 38-plex Luminex, and immune cell functional phenotypes via 14-color flow cytometry, PRR activation screening and ELISA. We collected clinical parameters from medical and surgical records and examined whether there were any associations between endotype and clinical features.

Results: Our studies suggest four clinically actionable human endotypes associated with biopsy-proven IRI centered on the involvement of specific DAMP-PRR signaling pathways: 1) disulfide-HMGB1/TLR4/TNFa, 2) cfDNA/HMGB1/RAGE/TLR9, 3) ssRNA/TLR7 and 4) PGN/NOD2. High-risk IRI endotypes 1 and 2 are associated with increased myeloid activation/infiltration, circulating IL-2, IL-3, IL-4, IL-7, IL-13, IL-1a, IL-17A, IL-1RA, CCL11 and de novo HLA donor-specific antibodies, as well as poorer outcomes, including ACR, AMR and death. Low-risk IRI endotypes 3 and 4 are associated with increased tolerance induction in myeloid and T cells leading to improved outcomes and extended allograft/patient survival. Importantly, we identified female Hispanics with NASH as primarily having high-risk IRI endotype 1. Additionally, high-risk IRI endotype 2 is seen in patients with non-active hepatocellular carcinoma (HCC) at the time of transplant, whereas those with active HCC frequently have low-risk IRI endotypes 3/4.

Conclusions: Clinical presentations are directly associated with inflammatory endotypes in OLT-IRI. Accurate endotyping of patients according to their specific pathogenesis will allow more precise and personalized therapeutic strategies to reduce the influence of IRI on OLT outcomes.

Abstract# LB 12

One-year Outcomes of a Multicenter Trial of Transplantation of Hcv Viremic Kidney Donors into Hcv Uninfected Recipients

M. Sise[1], D. Goldberg[2], D. Schaubel[3], J. Kort[4], R. Alloway[5], J. Friedewald[6], R. Fontana[7], S. Sultan[8], N. Desai[9], R. Chung[1], P. Reese[10], *[1]Mass General Hospital, Boston, MA, [2]U-Miami, Miami, FL, [3]U. Pennsylvania, Philadelphia, PA, [4]Abbvie, Chicago, IL, [5]U Cincinnati, Cincinnati, OH, [6]Northwestern U., Evanston, IL, [7]U. Michigan, Ann Arbor, MI, [8]Cornell, New York City, NY, [9]Johns Hopkins, Baltimore, MD, [10]U. Pennslyvania, Philadelpha, PA*

Purpose: As interest in transplantation of Hepatitis C virus (HCV)-viremic kidneys into HCV-uninfected (HCV^+ to HCV^- KT) recipients increases, understanding clinical outcomes beyond HCV clearance with direct-acting antivirals is important. We report the one-year outcomes of the seven-center MYTHIC (Multi-center studY to Transplant Hepatitis-C InfeCted Kidneys) trial.

Methods: Donors were HCV RNA positive, had any HCV genotype, with KDPI < 85. The 30 KT recipients were treated with Glecaprevir-pibrentasvir (G/P) for 8 weeks, starting 2-5 days post-KT. We assessed the following 1 year post transplant: HCV virologic status, Cytomegaloviurs (CMV), and polyoma virus (BK) infection, transplant rejection, graft function, and patient survival. We performed a comparison of time-to-transplant with recipients of non-HCV infected kidneys derived from UNOS and matched based on a multivariate risk score.

Results: Seventy-six patients were consented for evaluation, 12 were excluded, and of 64 eligible patients, 30 underwent kidney transplant from HCV-viremic donors after a median of 6.3 weeks (IQR, 1.9-10.1). Patients enrolled in the MYTHIC trial were significantly more likely to receive a kidney transplant compared to risk-score matched UNOS comparators (N=642) **(Figure)**. All 30 participants achieved durable HCV clearance and no patient developed clinically significant liver disease. There were 9 cases of detectable CMV viremia in the first year post-transplant, with 4 cases having > 1000 IU/mL. There were 4 cases of BK viremia > 1000 IU/mL. One year survival was 93%; there were two deaths after HCV cure (*Staph aureus* bacteremia and unexplained death at home). There were 3 cases of biopsy-confirmed acute rejection. One year graft function among the 28 surviving patients was excellent (mean serum creatinine 1.27mg/dL, SD 0.41).

Conclusions: One year findings from the first multicenter standardized trial of pre-emptive G/P after HCV+ to HCV- KT demonstrate that this approach is highly effective, with excellent patient outcomes and shortened waitlist time to transplant.

Abstract# LB 13

Comprehensive Utilization of HCV Viremic and Non-Viremic Donor Livers and Kidneys into HCV-negative Patients

M. E. de Vera, J. Woloszyn, J. Sterris, M. Robinson, R. Evans, S. Blais, B. Elhazin, C. Amador, c. Berk, M. Volk, R. Villicana, *Transplant Institute, Loma Linda University Health, San Bernardino, CA*

Purpose: We report our experience on virologic and graft outcomes of HCV-negative patients transplanted with HCV NAT+ (viremic) and HCV Ab+/NAT- (non-viremic) livers and kidneys from 2017 to 2020.

Methods: All recipients were HCV RNA- pretransplant. HCV Ab and RNA testing was done 1-, 3-, and 12-months post-transplant. Non-viremic organs were routinely offered to patients after informed consent. Patients transplanted viremic organs were enrolled in IRB-approved studies, and after confirmation of HCV RNA positivity were treated for 12 weeks (kidney patients with Epclusa, liver patients with Mavyret or Harvoni).

Results: Kidney and liver recipients received thymoglobulin and Basilixumab, respectively. Immunosuppression consisted of tacrolimus and steroids ± MMF. *HCV Ab+/NAT- (non-viremic) donor organs*: 91 kidney and 19 liver patients have been transplanted (Table). 40 (44%) kidney and 7 (37%) liver recipients seroconverted, becoming HCV Ab+ post-transplant. However, no HCV transmission occurred in kidney transplant patients (100% HCV RNA negative with follow-up post-transplant of 25.1±13.5 months) and only 1 (5%) liver patient became HCV RNA positive but achieved SVR with treatment (follow-up post liver transplant, 21.4±10.3 months). *HCV NAT+ (viremic) donors*: 8 kidney and 7 liver patients have been transplanted; all were HCV RNA- prior to transplant. 13 patients were Genotype 1a and 2 were Genotype 3 (1 liver, 1 kidney). No patients were denied HCV treatment; insurance authorization was 100%. Mean follow-up post kidney transplant was 5±1.7 months. Patients started treatment 3.9 ± 0.9 weeks post-transplant. Seven of 8 kidney transplant patients are HCV RNA negative; 6 achieved SVR and the other patient was HCV RNA negative but died while on 10 weeks of treatment. The 8th patient recently started treatment. Mean follow-up post liver transplant was 14.1±7.1 months. Patients initiated treatment at 11.6±7.4 weeks post-transplant. All 7 (100%) liver recipients have achieved SVR. Side effects were minimal to none. *Graft outcomes*. One-and 3-year kidney graft survival is 95% and 88%, respectively. One- and 3-year liver graft survival is both 95%.

Demographics		
	Kidney pts (99)	Liver pts (26)
Recipient age	57 ± 11	56±11
Recipient gender M:F	59:40	15:11
Donor age	43±13	44±15
Median KDPI	73.5	NA
MELD at Tx	NA	31±12
PHS-increased risk donor	55 (56%)	13 (50%)

Conclusions: Transplantation of HCV Ab+/NAT- liver and kidneys to HCV-negative recipients is safe; incidence of HCV transmission was 1/110 (0.9%). 100% of HCV-negative patients transplanted with HCV NAT+ organs achieved SVR. We propose that transplantation of HCV viremic and non-viremic liver and kidneys into HCV-negative patients become standard of care.

Abstract# LB 14

Detection of SARS-CoV-2 Specific Functional T Cells Using a Seven Color Flow Cytometry Assay

L. Flebbe-Rehwaldt, J. Hayden, K. Mickey, S. Manley, S. Kleiboeker, *Eurofins-Viracor, Lees Summit, MO*

Purpose: The need to evaluate SARS-CoV-2 immune responses is an important clinical research focus. Detecting neutralizing antibodies is one measure of immune response, but the ability to evaluate CD4 and CD8 T cell responses specific to SARS-CoV-2 is also an important measure of immune status. The role these two arms of the immune system play in protection is currently unknown.

Methods: We developed a whole blood flow cytometry assay that detects functional CD4 and CD8 responses to stimulation by peptide antigen pools encompassing the spike (S1 - receptor binding domain (RBD) and S2) and nucleocapsid (N) proteins to address this need. Activated T cells were defined as CD4 or CD8 T cells co-expressing the CD69 activation marker with IFN-γ, TNF-α or IL-2. Polyfunctional T cells, expressing multiple cytokines, were also identified. This assay was validated using whole blood from SARS-CoV-2 recovered volunteers and apparently normal donors who self-reported as uninfected by SARS-CoV-2.

Results: The range in responses varied by donor and was not correlated with the reported severity of their disease. A positive response was defined as a 3-fold increase in the number of activated T cells over the unstimulated control. Of the 32 SARS-CoV-2 recovered donors tested, 25 responded to two or three of the peptide pools and five did not respond to any SARS-CoV-2 peptides. Responses ranged from 0.03% up to 1.23% of the CD4 or CD8 population. The responding T cells were predominantly CD4, but when CD8 T cells responded they tended to recognize the nucleocapsid peptides most strongly. Data from one individual with a robust response are shown below.

Table 1. Percent responding T Cells				
Cell populations	**No stim**	**S1 (RBD)**	**S2**	**N**
CD4+CD69+IFNγ+	0.00	0.46	0. 20	0.16
CD4+CD69+ TNFα+	0.03	0.78	0.32	0.35
CD4+CD69+IL-2	0.01	0.71	0.27	0.34
CD4+CD69+IFNγ+TNFα+IL-2+	0.0	0.40	0.16	0.14
CD8+CD69+IFNγ+	0.03	0.03	0.02	0.12
CD8+CD69+ TNFα+	0.03	0.05	0.02	0.08
CD8+CD69+IL-2	0.01	0.01	0.00	0.02
CD8+CD69+IFNγ+TNFα+	0.00	0.01	0.00	0.06

For uninfected donors, five of 21 showed a low, but detectable response to stimulation with at least one peptide pool. These responses could be attributed to an asymptomatic infection, or to cross-reactive T cells specific to one of the seasonal respiratory coronaviruses.

Conclusions: In summary, we developed a sensitive assay to detect SARS-CoV-2 spike- and nucleocapsid-specific T cell responses in whole blood samples. This assay will be valuable in monitoring SARS-CoV-2 T cell response and duration in infected individuals. Measuring the T cell responses to SARS-CoV-2 vaccinated individuals is currently under investigation.

Abstract# LB 15

Impaired Antibody Responses to Spike Protein Antigens of Sars-cov-2 in Solid Organ Transplant (sot) Recipients

C. Ashokkumar[1], S. Nadig[2], V. Rohan[2], A. Kroemer[3], H. Dhani[3], S. Rao[4], R. Sindhi[5], *[1]Plexision, pittsburgh, PA, [2]Medical University of South Carolina, Charleston, SC, [3]MedStar Georgetown Transplant Institute, Georgetown, DC, [4]DHR Health Institute for Research and Development, Texas, TX, [5]University of Pittsburgh, Pittsburgh, PA*

Purpose: Chronic immunosuppression can impair antibody responses after natural infection and vaccination in SOT recipients. It is not known whether antibody responses are impaired in SOT compared with non-SOT patients with COVID-19

Methods: We evaluated IgG responses to the spike (S) and receptor binding domain (RBD) antigenic sequences of SARS-CoV-2 after COVID-19-infection in SOT and non-SOT patients using enzyme-linked immunosorbent assay (ELISA). The S protein consists of a conserved C-terminal and less conserved N-terminal S1 sequence which contains the RBD. An optical density (OD) at 490 nm of 0.45 or greater, or < 0.45 was read as positive and negative ELISA result based on pre-clinical validation in 148 subjects. S1-reactive, S2-reactive and S-reactive CD4 cells that expressed CD154 were measured with flow cytometry after overnight stimulation with respective peptide mixtures for these antigens.

Results: 204 total study subjects, mean+/-SD age 47.5+/-21 years, were sampled at mean 12.6 (range 0-94) days after diagnosis. Subjects included 107 males, 74 SOT (liver-48, kidney-26) and 130 non-SOT. Among them, 103 patients with COVID-19 included 32 SOT and 71 non-SOT. Antibody measurements were performed in 74 COVID-19 patients. Fifty one of 74 patients received convalescent plasma. Anti-spike and anti-RBD IgG were present in 49 of 51 (96%) and 47 of 51 (92%) patients, respectively. Among the remaining 23 patients who did not receive plasma, anti-spike IgG and anti-RBD IgG were present in 21 (91%) and 16 (69.5%) patients, respectively. The incidence of anti-RBD IgG was significantly lower in SOT, 2 of 7 or 29%, compared with non-transplant patients, 14 of 16 or 88% (p=0.011). Between-group differences in the incidence of anti-spike IgG were not significant (5/7 or 71% SOT vs 16/16 or 100% SOT, p=NS). One of 23 patients, an SOT recipient died and showed no IgG to S or RBD antigens. Antibody titers reflected in OD490 readings were lower in SOT compared with non-SOT for anti-spike IgG (mean 2.2+/-0.6 vs 1.4+/-1.2, p=0.16, NS) and anti-RBD IgG (1.8+/-0.9 vs 0.54+/-0.7, p=0.004). Subjects without and with anti-RBD antibody did not differ in timing of the sample from diagnosis (mean+/-SD 18+/-12.5 vs 12+/-12, p=0.258, NS, respectively), frequencies of S-, S1 or S2-reactive T-cells (mean 3.1+/-2.4% vs 1.8+/2%, p=0.225, NS, respectively), or proportions of patients requiring intubation (2/7 or 29% vs 4/16 or 25%, p=1.00, NS, respectively).

Conclusions: Chronically immunosuppressed liver and kidney transplant recipients demonstrated impaired antibody responses to SARS-CoV-2 spike antigens, especially to less conserved RBD-containing viral sequence. This finding may portend impaired vaccine efficacy in transplant recipients.

Abstract# LB 16

Precision Medicine in Renal Transplantation: Structural Biology of HLA Defines Allelic Binding of Cardinal Pathogenic Viruses in Transplantation

K. R. Sherwood[1], A. Nguyen[2], J. Tran[1], O. Gunther[3], A. Nellore[2], R. Thompson[2], J. Lan[1], L. Allan[1], P. A. Keown[1], *[1]Vancouver General Hospital, Vancouver, BC, Canada, [2]Biomedical Engineering, Oregon Health & Science University, Portland, OR, [3]Gunther Analytics, Vancouver, BC, Canada*

Purpose: The incidence, clearance and clinical expression of viremia post-Tx are heterogeneous, complicating prediction, prognosis and therapy. We postulated that variation viral presentation related to HLA type may inform understanding, and we used in silico methods to assess the MHC-peptide binding affinity for three important phylogenetically distinct viruses (SARS-CoV-2, CMV and BKV).

Methods: Carrier frequencies for 11 HLA genes (HLA-A, B, C; DRB1, DRB3/4/5, DQA1, DQB1, DPA1, DPB1) were determined by NGS in 1150 renal transplant recipients. All FASTA-formatted viral protein sequence data from the NCBI RefSeq database were kmerized into 8-12 mers. Using netMHCpan, MHC-peptide binding affinities were predicted and affinity scores <500nM were included in the HLA allele rankings

Results: A total of 206 Class I HLA alleles identified in 1150 patients exhibited population frequencies ranging from 0.09% to 30%. Within this repertoire, peptide binding varied dramatically identifying low- and high-affinity alleles for each of the three viral proteomes. Alleles with lowest binding propensity were specific to each virus (e.g. HLA-B*46:01 for SARS-CoV-2, HLA-B*51:05 for CMV and HLA-B*15:08 for BKV). In contrast, alleles with the highest binding propensity were remarkably uniform for all 3 viruses (e.g. HLA-A*02:11 top for all three virus proteomes). Sequence signatures for HLA isoforms in the same allele group defined high or low binding characteristics, the difference being conferred by as little as a single amino acid within the peptide binding region (e.g. HLA-B*15:08 vs B*15:03). Carrier rates for predicted SARS-CoV-2 susceptibility/resistance genes in the transplant population were observed to be similar to global population carrier rates (Fig 1).

Conclusions: Evaluation of peptide binding provides a unique insight into viral recognition. If confirmed in our current proof-of-principle study comparing sequence and outcome in a large Canadian population, this data may offer a vital biomarker to define risk and treatment within conventional virological patient strata following transplant.

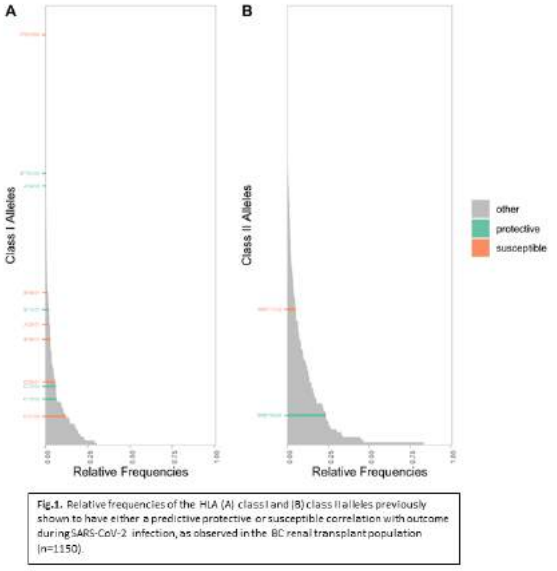

Fig.1. Relative frequencies of the HLA (A) class I and (B) class II alleles previously shown to have either a predictive protective or susceptible correlation with outcome during SARS-CoV-2 infection, as observed in the BC renal transplant population (n=1150).

Abstract# 437

Results of the APP Practice Survey: Do APPs Practice at the Top of Their Scope of Practice?

H. Domingo[1], D. Krieger[2], B. Muth[3], A. Frank[4], A. Borth[5], H. McDade[5], K. Paolini[6], A. Mayfield[5], M. Siegfried[7], J. Yoo[8], H. Hoy[9], N. McCormick[10], *[1]Northwestern University, Chicago, IL, [2]University of California-San Francisco, San Francisco, CA, [3]University of Wisconsin, Madison, WI, [4]Medstar Georgetown University, Annandale, VA, [5]University of Maryland, Baltimore, MD, [6]Erie County Medical Center, Grand Island, NY, [7]Swedish Organ Transplant, Seattle, WA, [8]Rush University, Chicago, IL, [9]University of Alabama - Huntsville, Huntsville, AL, [10]University of Colorado-Denver, Denver, CO*

Purpose: Transplant centers employ Advance Practice Providers (APPs) in response to physician trainee work hour restrictions and to increase patient access to transplant care. APPs have completed advance training and certification in order to manage medical conditions in inpatient and outpatient settings.

Methods: Questions to determine if APPs are practicing at the top of their scope of practice were included in the AST APP Practice survey. Top of scope of practice is defined as delivering healthcare to the fullest extent of the APP license as allowed by state laws and regulations.

Results: APPs (n-253) from 32 states and DC completed the survey. 26.2% of APPs were not working at the top of their scope of practice. Reasons include inability to perform procedures, inadequate training, restrictive hospital protocols. 8.6% function as a scribe, 29.7% were expected to function as a coordinator. Though 92.9% of inpatient APPs worked with transplant coordinators, they schedule follow up appointments (56.8%), arrange home health care (50.5%), obtain prior authorizations (40.6%). 95.5% of outpatient APPs worked with transplant coordinators, but still schedule tests and procedures (49.9%), obtain prior authorizations (31.9%), deal with insurance issues (34.5%), and facilitate medication assistance programs for patients (29.5%). 87.7% of outpatient APPs conduct independent clinic visits, 47.2% write clinic notes for physician review or cosign as part of their job. 17.8% run specialized APP clinics like transplant urgent care and delayed graft function clinics. APP duties are in table 1.

Inpatient APP Duties		Outpatient APP Duties	
Enter Orders	176 (91.7%)	Enter Orders (tests, labs, medications, imaging)	140 (85.9%)
Daily Rounds	173 (90.1%)	Wound Care	100 (61.4%)
Write Progress Notes	172 (89.6%)	Write Clinic Notes for Independent Clinic Visit	143 (87.7%)
Consults	137 (71.4%)	Write Clinic Notes for Physician Review or Cosign	77 (47.2%)
Admissions/Discharges	156 (81.3%)	Admit Patients from Clinic (Direct admission)	129 (79.1%)
Donor run/organ procurement	22 (11.5%)	Respond to Electronic Patient Messages	118 (72.4%)
Schedule Followup Appointments	109 (56.8%)	Schedule Tests, Procedures, Imaging	81 (49.9%)
Arrange Home Health Care	97 (50.5%)	Home Care Orders	68 (41.7%)
Order Durable Medical Equipment	102 (53.1%)	Adjust Medications	141 (86.5%)
Obtain Consents	133 (69.3%)	Obtain Consents	73 (44.8%)
Perform procedures	89 (46.4%)	Perform Office Procedures	76 (46.3%)
Patient Education	91 (47.4%)	Post-Transplant Education (or new transplant recipients)	96 (58.9%)
Obtain Prior Authorizations	78 (40.6%)	Obtain Prior Authorizations	52 (31.9%)
Assist in the OR	30 (15.6%)	Order Infusion Therapies	108 (66.3%)
Leadership/Management Responsibilities	74 (38.5%)	Leadership/Management Responsibilities	72 (44.2%)
		Lab Review	147 (90.2%)
		Facilitate Medication Assistance Programs for Patients	48 (29.5%)
		Deal with Insurance Issues	56 (34.5)
		Coverage for other Providers (Lab Review, Patient Concerns)	116 (71.2%)
		Triage Phone Calls from Patients	89 (54.6%)
		Run APP Specialized Clinic (ie: DGF, Urgent Care, etc)	29 (17.8%)

Conclusions: With the increasing burden of healthcare costs, every team member should practice to their full potential. With appropriate training and experience, APPs can manage highly complex patients and perform a wide range of procedures. A significant percentage currently perform duties more appropriately delegated to nurse coordinators or case managers. By optimizing APPs' role, time spent performing these tasks can be allocated to seeing more patients, thus improving patient access to health care as well as APP job satisfaction and retention.

Abstract# 438

Covid-19 Incidence Was Initially Associated with Posttransplant Kidney Graft Failure

A. Wey[1], J. Miller[1], D. Musgrove[1], N. Salkowski[1], M. Tabaka[1], R. Hirose[2], A. Massie[3], D. Segev[3], A. Israni[1], J. Snyder[1], B. Kasiske[1], *[1]SRTR, Minneapolis, MN, [2]Univ of San Francisco, San Francisco, CA, [3]Johns Hopkins, Baltimore, MD*

Purpose: To better understand the effect of COVID-19 on kidney posttransplant outcomes, we estimated the association of county-level COVID-19 incidence with kidney posttransplant graft failure.

Methods: The study used a period-prevalent cohort of kidney recipients from March 13, 2019 to July 31, 2020 who received a transplant on or after January 1, 2000. The county-level incidence of COVID-19 for each kidney transplant program was determined from the *New York Times* database and aggregated into cases per 1,000,000 for each week before and after the national emergency declaration for COVID-19.

Results: For each week, recipients were given the county-level incidence of the transplant program during the previous week. A two-dimensional spline estimated the effect of COVID-19 across calendar time and incidence.

Conclusions: The effect of COVID-19 incidence had a nonlinear relationship with kidney graft failure, and the effect changed over the course of the pandemic. At the time of the national emergency declaration (March 13 to 19, 2020), the incidence of COVID-19 had a nonlinear effect (Figure 1, left panel): relatively flat up to an incidence of about 16, then the effect rapidly increased to a hazard ratio of about 3, for an incidence of 1024. This nonlinear effect attenuated during the weeks after the declaration of a national emergency. Roughly 10 weeks after the emergency declaration (May 22 to 28, 2020), the incidence of COVID-19 had a less dramatic effect on posttransplant graft failure rates (Figure 1, right panel). Thus, the emergence of COVID-19 coincided with a significantly higher rate of kidney graft failure, potentially from COVID-19 infection or patients not seeking for-cause medical care. However, after the initial disruption, kidney graft failure rates were less strongly associated with COVID-19 incidence, suggesting that kidney recipients and/or transplant programs may have adapted to the new conditions imposed by COVID-19.

Abstract# 439

Centre Variation in Emergency Hospital Readmissions Following Renal Transplantation in England

J. Peracha[1], D. Pitcher[1], R. Steenkamp[1], J. Medcalf[2], G. Lipkin[3], D. Nitsch[4], W. McKane[5], *[1]UK Renal Registry, Bristol, United Kingdom, [2]John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom, [3]University Hospitals Birmingham, Birmingham, United Kingdom, [4]London School of Hygiene and Trpoical Medicine, London, United Kingdom, [5]Sheffield Kidney Institute, Northern General Hospital, Sheffield, United Kingdom*

Purpose: Emergency hospital readmissions (EHR) following surgery are associated with significant patient distress, morbidity and costs to healthcare providers. In this study we aim to describe and compare, for the first time, EHR following adult renal transplantation across England.

Methods: We undertook a retrospective analysis of linked English '*Hospital Episodes Statistics*' and '*UK Renal Registry'* datasets to identify EHR within 120 days of initial discharge for adult renal transplant recipients, across 19 centres (2012-2016). All elective and day case admissions were excluded. Logistic regression was

used to calculate odds ratios for readmission associated with age, sex, ethnicity, deprivation, transplant type (live donor LD or deceased donor DD) and length of stay (LOS) at time of surgery. Coded primary diagnoses were also explored in an attempt to try and characterise the main reasons for readmissions.

Results: 12156 adult renal transplants were performed in England between 2012-2016 (8299 DD and 3857 LD). 44% of patients had an EHR within 120 days of their initial discharge, varying between 30-72% across centres. Median LOS for EHRs was 3 days (IQR 2-7 days). 25% of EHRs had LOS=1 day however and variation in EHRs requiring longer hospital stays were therefore explored separately (Figure 1). Risk factors for readmission included advancing age, female sex, DD kidney and longer LOS following initial surgery. The proportion of readmitted patients with commonly coded primary diagnoses are shown in Table 1.

Conclusions: We found high rates of EHR for adult renal transplant recipients. There was a clear centre effect noted and patient/transplant level factors will need to be explored further, alongside individual transplant unit care pathways and outpatient follow-up intensity to allow better understanding of reasons underlying this variation and how services might be best tailored to address it.

Table 1: Coded Primary Diagnosis Groupings for patients with 120 day Emergency Readmissions

Primary Diagnosis Grouping	% of readmitted patients with associated codes	Centre Variation (%)
Renal Impairment	24.4	15-48
Urinary tract infections	9.4	4-18
Gastrointestinal symptoms	8.6	3-14
Unspecified Complications of kidney transplant	7.4	2-14
Surgical Complications (including those related to wound/haematoma/surgical site infections)	7.0	3-12
Other infections (sepsis/chest)	4.8	2-8
Obstructive Uropathy	3.4	1-10

Abstract# 440

Results of the Transplant Advance Practice Provider Survey: Opportunities for APPs to Contribute to Academic Pursuits

B. Muth[1], D. Krieger[2], N. McCormick[3], M. Siegfried[4], H. Domingo[5], J. Yoo[6], A. Frank[7], K. Paolini[8], A. Mayfield[9], H. McDade[9], A. Borth[9], H. Hoy[10], *[1]University of Wisconsin, Madison, WI, [2]UCSF, San Francisco, CA, [3]University of Colorado, Denver, CO, [4]Swedish Organ Transplant, Seattle, WA, [5]Northwestern, Chicago, IL, [6]Rush, Chicago, IL, [7]Medstar Georgetown University, Annandale, VA, [8]Erie County Medical Center, Grand Island, NY, [9]University of Maryland, Baltimore, MD, [10]University of Alabama - Huntsville, Huntsville, AL*

Purpose: The pillars of academic medicine are research, education and patient care. While transplant Advance Practice Providers (APPs) are primarily recruited for clinical roles, many are interested in the academic pursuits of education and research.

Methods: Questions about APP research and teaching opportunities were included in the AST APP Practice survey, a 58-item electronic questionnaire. Questions were non-sequential, therefore, participants were not required to answer all questions. The survey was distributed via a link posted on the APP COP Hub, emailed to members of the AST APP community of practice and to ASTS APPs (n=307), and sent out on twitter. Recipients were encouraged to share the link with colleagues. We received 253 responses from 32 states and the District of Columbia, and represent all 11 UNOS regions.

Results: 147 (58.8%) of APPs participate in academic or leadership activities at their institution: 105 (41.7%) have published abstracts, papers, editorials or book chapters, 84 (33.2%) have presented at regional or national meetings and 165 (65.2%) have attended a National transplant meeting (ATC, ASTS, CEOT). Notably, 189 (77.1%) of respondents would like to increase their participation in research, however, the biggest obstacles are lack of time (49%), lack of opportunity (32%), lack of experience (5%).

228 (90.8%) of APPs have the opportunity to teach in some capacity: 175 (69.1%) train physician trainees and 216 (86.4%) precept other APPs. 89 (35.1%). Respondents would like to teach or mentor at some level, whether to APP peers or physician trainees, however, the barriers to teaching are time (28%), opportunity (14%), lack of experience (10.5%) and unsupported activity by their institution (9%). Academic demographics of respondents are in table 1

Table 1: Transplant Advance Practice Provider Academic Demographics

APP Academic Activities	
• Published (abstract, paper, editorial or book chapter)	105 (41.67%)
• Invited Speaker	109 (74.15%)
• Give Grand Rounds	30 (20.41%)
• Leadership Role in Department or APP group	88 (59.88%)
• Teach/Precept (APPs, physician trainees)	228 (90.8%)
• Presented at a National Transplant Meeting	84 (33.2%)
• Participate on an APP Advisory Board at Local Institution	40 (27.21%)
Years of Practice in Transplant	
• < 5 years	132 (52.38%)
• 6-10 years	70 (27.78%)
• 11-15 years	30 (11.90%)
• 16-20 years	13 (5.15%)
• > 21 years	7 (2.78%)
Practice at Academic Center	246 (97.23%)
Transplant Center Location	
• Northeast	68 (27.2%)
• Midwest	71 (28.4%)
• Southeast	37 (14.8%)
• West	49 (19.6%)
• Southwest	25 (10%)
Estimated Transplant Center Volume for Organ Type APP Practices in	
• <50/year	38 (15.26%)
• 51-100/year	43 (17.27%)
• 101-200/year	65 (26.10%)
• 201-300/year	33 (13.25%)
• 301-400/year	38 (15.26%)
• >400/year	32 (12.85%)

Conclusions: Because of their predominantly clinical role, APPs find similar barriers to research and teaching. As practitioners of evidence based medicine, transplant APPs are uniquely positioned to generate practice-based evidence. We encourage our physician colleagues and transplant teams to partner with APPs to cultivate a favorable atmosphere for clinical research and education.

Abstract# 441

A Comparison of Pediatric Intestine Transplant Between the Current Era (2015-2019) and the Peak Period (2002-2006)

S. Horslen[1], T. Weaver[2], M. Skeans[2], *[1]Seattle Children's Hospital, Seattle, WA, [2]SRTR, Minneapolis, MN*

Purpose: Demand for intestine transplants in children grew from its clinical inception in the late 1980s to a peak in 2007 of 111 small bowel-containing transplants. This was driven by improved posttransplant survival and high pretransplant mortality due to complications of life on total parenteral nutrition, mostly sepsis, loss of central venous access, and progressive liver disease. With the establishment of dedicated intestinal failure programs promoting coordinated medical, nutritional, and surgical care, the pretransplant mortality rates declined as did the referral and listing of infants and children for intestine transplant. This study aims to detail the differences between recipient cohorts in 2 5-year eras around the 2007 peak: January 2002-December 2006 and January 2015-December 2019.

Methods: All intestine transplant recipients younger than 18 years at listing are included. For the 2 eras, we present summary statistics of recipient characteristics at transplant and Kaplan-Meier estimates of posttransplant survival.

Results: The number of intestine-containing pediatric transplants fell from 420 in the first era to 245 in the second (Table 1). Median age at transplant increased from 2 to 5 years (mean, 4.2 vs 6.5); the most noticeable change being a reduction in recipients <2 years old, from 56.7% in the first era to 22.4% more recently, and a reciprocal increase in the 2- to 10-year age group (30.5% vs 60.0%). The fraction of retransplant (any previous transplant) more than doubled, from 9.3% in the first era to 22.9% in the second. Short bowel syndrome was the predominant cause of intestinal failure in both cohorts. Patients also waited longer from listing until transplant.

Conclusions: Advances in intestinal failure management resulted in the need for fewer transplants at older ages, with no detriment in posttransplant survival.

Table 1: Transplant Characteristics of Pediatric Intestine Transplant Recipients by Transplant Year

	Total	2002-2006	2015-2019
Characteristic	N (%)*	N (%)*	N (%)*
All

Abstract# 442

Atg16l-Dependent Autophagy Attenuates Procession of Renal Interstitial Fibrosis in Chronic Renal Graft Dysfunction via Regulating Tumor Necrosis Factor Alpha (tnf-α) Induced Endmt

Z. Gui, Z. Wang, Z. Han, J. Tao, X. Ju, R. Tan, M. Gu, *The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Purpose: Chronic renal graft dysfunction is characterized by inflammation, tubular injury, and interstitial fibrosis. We have confirmed that endothelial-mesenchymal transition (EndMT) was one of important sources to allograft interstitial fibrosis. However, whether and how autophagy contributes to renal allograft fibrosis remains unclear. ATG16L is a critical autophagy-related gene (ARG) for autophagosome formation.

Methods: The GEO database was searched and data was retreived. 60 allograft tissues were collected from renal transplant recipients with chronic allograft dysfunction (CAD) to explore the autophagy in kidney transplantation. Moreover, cell culture was performed and human umbilical artery endothelial cells (HUAECs) and human renal glomerular endothelial cells (HRGECs) were induced by TNF-α. Autophagy in endothelial cells was examined and signaling pathway was tested.

Results: Here, we observed ATG16L, as one significant differential ARG, was lower expression in chronic allograft dysfunction (CAD) group compared with non-rejecting by analyzing data sets from Gene Expression Omnibus (GEO). The same results were obtained in 60 kidney transplanted patients with CAD that there are less autophagosome and autolysosome in transplated kidneys, and downregulation of autophagy related to poor prognosis. In addition, we found that TNF-α could induce EndMT in human umbilical artery endothelial cells (HUAECs) and human renal glomerular endothelial cells (HRGECs), and knockdown of ATG16L facilitated this process. In vivo, we demonstrated abundance of ATG16L related to the dynamic autophagic flux change along different stages of kidney transplantation and autophagy activation alleviated the progression of EndMT, interstitial extracellular matrix deposition and inflammatory cell infiltration by increasing ATG16L expression. Mechanistically, loss of ATG16L specifically in endothelial cells reduced SQSTM1/p62-dependent autophagic degradation of NF-κB and resulted in production of TNF-α.

Conclusions: ATG16L-dependent autophagy served as a negative regulator of TNF-α-induced inflammation, EndMT and the development of renal graft fibrosis, therefore, autophagy could be used as a potential therapeutic target for chronic renal graft rejection.

Abstract# 443

Single-Cell RNA-seq Identifies Intra-Graft Population Heterogeneity in Acute Heart Allograft Rejection in the Mouse

C. Wu[1], Y. Tang[1], X. Shi[1], X. He[1], X. Li[2], *[1]The First Affiliated Hospital,Sun Yat-sen University, Guangzhou, China, [2]Immunobiology & Transplant Sciences Houston Methodist Hospital, Houston, TX*

Purpose: Transplant rejection remains a major barrier to graft survival and involves a diversity of cell types. But the heterogeneity in a given cell type in graft rejection remains poorly defined.

Methods: In the present study, we used single-cell RNA sequencing (scRNA-seq) technology, which is a powerful tool in identifying population heterogeneity, to examine changes in graft infiltrating cells during acute heart allograft rejection.

Results: Here we focused on innate cells and performed the first comprehensive analysis of transcriptional heterogeneity in the mouse. In dimensionality reduction and unsupervised cell clustering analysis, we identified 21 distinct cell populations in the allografts. We showed that macrophages can be divided into five subclusters and revealed a new subset of macrophages highly associated with graft rejection; they upregulated CD40, Fam26f and Pira2. Furthermore, we confirmed the heterogeneity of graft endothelial cells in rejection, which showed five subclusters (EC1~EC5) and the EC5 can function as antigen presenting cells during transplant rejection. We further identified Ubiquitin D (Ubd) in EC5 cluster as a key marker of rejection, which was validated by immunohistochemistry staining in mouse cardiac samples and human kidney biopsy specimens.

Conclusions: our findings revealed the population heterogeneity of cell types in acute allograft rejection and identified novel markers in rejection.

Abstract# 444

Extracellular Matrix Injury of Kidney Allografts in Antibody-mediated Rejection

S. Clotet Freixas[1], C. McEvoy[1], I. Batruch[2], C. Pastrello[3], M. Kotlyar[3], J. Van[1], M. Arambewela[1], A. Boshart[1], S. Farkona[1], Y. Niu[3], Y. Li[1], O. Famure[1], A. Bozovic[4], V. Kulasingam[4], P. Chen[1], J. S. Kim[1], E. Chan[5], S. Moshkelgosha[1], S. A. Rahman[6], J. Das[6], T. Martinu[1], S. Juvet[1], I. Jurisica[3], A. Chruscinski[1], R. John[1], A. Konvalinka[1], *[1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [2]Department of Laboratory Medicine and Pathobiology, Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada, [3]Krembil Research Institute, University Health Network, Toronto, ON, Canada, [4]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada, [5]Department of Medicine, Division of Nephrology, University Health Network, Toronto, ON, Canada, [6]Center for Systems Immunology, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Purpose: Antibody-mediated rejection (AMR) accounts for >50% of kidney graft losses. AMR is caused by donor-specific antibodies (DSA) against HLA and non-HLA antigens in glomeruli and tubulointerstitium, which together with cytokines such as tumor necrosis factor alpha (TNFα), trigger graft injury. The mechanisms governing cell-specific injury in AMR remain unclear.

Methods: We studied 30 for-cause kidney biopsies with early AMR, acute cellular rejection (ACR) or acute tubular necrosis (ATN). We laser-captured and microdissected glomeruli and tubulointerstitium and subjected them to unbiased proteome analysis.

Results: Machine learning revealed that the intensities of all quantified proteins (>2000 per compartment) accurately discriminated AMR from ACR and from ATN ($P<0.05$). In each compartment, >200 proteins were significantly dysregulated in AMR, compared to ACR and/or ATN ($P<0.05$). Basement membrane and extracellular matrix (ECM) proteins were significantly decreased in AMR. We verified decreased glomerular and tubulointerstitial LAMC1 expression, and decreased glomerular NPHS1 and PTPRO expression in AMR. Cathepsin-V (CTSV) was predicted to cleave ECM-proteins in the AMR glomeruli. We identified galectin-1, an immunomodulatory protein upregulated in the AMR glomeruli and linked to the ECM. Anti-HLA class-I antibodies significantly increased CTSV expression, and galectin-1 expression and secretion, in human glomerular endothelial cells. Glutathione S-transferase omega-1, an ECM-modifying enzyme, was significantly increased in the AMR tubulointerstitium, and in TNFα-treated proximal tubular epithelial cells.

Conclusions: Basement membranes are often remodeled in chronic AMR. We demonstrated that this remodeling begins early in glomeruli tubulointerstitium. Targeting ECM-remodeling in AMR may represent a new therapeutic opportunity.

Abstract# 445

Laminin Alpha 4 and Alpha5 Differentially Regulate Lymph Node Tolerogenic Structure

L. Li[1], M. Shirkey[1], W. Piao[1], Y. Xiong[1], V. Saxena[1], T. Zhang[1], J. Iyyathurai[2], R. Lakhan[1], R. Abdi[3], J. Bromberg[1], *[1]Surgery, UMB, Baltimore, MD, [2]CVID, UMB, Baltimore, MD, [3]Harvard University, Boston, MD*

Purpose: Lymph node (LN) stromal laminins α4 (Lama4) and α5 (Lama5) are associated with tolerance and immunity, respectively. We hypothesized that stromal Lama4 and Lama5 regulates lymph node (LN) structure to channel T cell distribution and functions.

Methods: LN stromal cell Lama5 conditional KO (Pdgfrb-Cre$^{+/-}$ x Lama5$^{fl/fl}$), and Lama4 KO (Pdgfrb-Cre$^{+/-}$ x Lama4$^{fl/fl}$) mice were created. High endothelial venules (HEV), Treg distribution, chemokines, and cell adhesion molecules in the LNs analyzed by immunohistochemistry and qRT-PCR. Mice received cardiac allografts and monitored for survival.

Results: Compared to wild type (WT) controls, depleting Lama5 created a tolerogenic niche in LN. The Lama5 KO LNs were characterized by greater HEV size and numbers, increased numbers of Treg and dendritic cells (DC), increased chemokine CCL19, CCL21 and CXCL12, upregulated cytokine IL-33, and more adhesion molecules ICAM-1 and VCAM-1 in CR and around HEVs. In contrast, depletion of Lama4 gave rise to a relatively inflammatory microenvironment. Compared to WT, the Lama4 KO LNs had fewer HEVs, less Treg, DCs, CCL19, CCL21 and CXCL12, downregulated IL-33, and less adhesion molecules in CR and around HEVs. BALB/c hearts were transplanted into Lama5 KO recipients and treated with low dose tacrolimus had significantly longer allograft survival (mean survival time (MST) 89 days versus MST 27.5 days in WT, (p<.002). Lama5 KO recipients receiving a single dose of anti-CD40L displayed a trend for increased survival (MST 155 vs 91 days, p=0.07). Tacrolimus treated Lama4 KO recipients had significantly shorter allograft survival (MST 11.5 days versus MST 18 days in WT (p<.002). Lama4 KO recipients receiving a single dose of anti-CD40L displayed a trend for decreased survival (MST 42.5 vs 60 days, p<0.01).

Conclusions: Depletion of Lama5 upregulated chemokines, adhesion molecules, DC and Treg in the T cell zones, CR, and around HEV, while depletion of Lama4 down-regulated those same cells and molecules in same areas. Lama5 deficient mice have a tolerant LN niche, while Lama4 deficient mice have a relatively immune LN niche. These results suggest targeting laminins are efficient approaches to modulate immune outcomes in transplantation.

Abstract# 446

Short-term Therapy with Anti-icam-1 Monoclonal Antibody Induced Long-term Liver Allograft Survival in Non-human Primates

S. Hong[1], D. Han[2], S. Lee[2], J. Kim[3], E. Hwang[3], H. Kim[4], J. Lee[5], K. Hong[1], E. Han[1], J. Cho[1], J. Lee[1], Y. Choi[1], K. Lee[1], N. Yi[1], J. Yang[1], K. Suh[1], *[1]Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic of, [2]Biomedical Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of, [3]Microbiology and Immunology, Seoul National University College of Medicine, Seoul, Korea, Republic of, [4]Pathology, Seoul National University College of Medicine, Seoul, Korea, Republic of, [5]Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of*

Purpose: Tolerance induction remains challenging following liver transplantation and the long-term use of immunosuppressants, especially calcineurin inhibitors, leads to serious complications. We aimed to test an alternative immunosuppressant, a chimeric anti-ICAM-1 monoclonal antibody, MD-3, for improving outcomes of liver transplantation.

Methods: We used a rhesus macaques liver transplantation model and monkeys were divided into three groups: no immunosuppression (n=2), conventional immunosuppression (n=4), and MD-3 (n=5).

Results: Without immunosuppression, liver allografts failed within a week by acute rejection. Sixteen-week-long conventional immunosuppression that consisted of prednisolone, tacrolimus, and an mTOR inhibitor, prolonged liver allograft survival; however, recipients died of acute T cell-mediated rejection (day 52), chronic rejection (day 62, 66) or adverse effects of mTOR inhibitor (day 32). In contrast, 12 weeks-long MD-3 therapy with transient conventional immunosuppression in the MD-3 group significantly prolonged the survival of liver allograft recipients (5, 96, 216, 412, 730 days; $P = 0.0483$). MD-3 effectively suppressed intragraft inflammatory cell infiltration, anti-donor T cell responses and donor-specific antibody with intact anti-cytomegalovirus antibody responses. However, this regimen ended in chronic rejection.

Conclusions: In conclusion, short-term therapy with MD-3 markedly improved liver allograft survival to 2 years without maintenance of immunosuppressant. MD-3 is therefore a promising immune modulating agent for liver transplantation.

Kidney

Kidney Alloimmune Responses

Abstract# 450

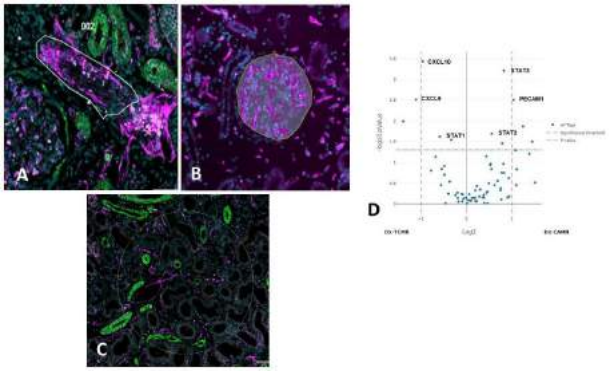
Digital Spatial Mrna Profiling Reveals Distinct Endothelial Transcripts in Dsa+ and Dsa- Endarteritis in Kidney Allografts

K. Tomaszewski[1], M. Araujo Medina[1], A. Bruce[1], P. Divakar[2], R. Smith[1], T. Kawai[3], R. Colvin[1], I. Rosales[1], *[1]Department of Pathology, Massachusetts General Hospital, Boston, MA, [2]NanoString Technologies, Inc., Seattle, WA, [3]Department of Surgery, Massachusetts General Hospital, Boston, MA*

Purpose: Renal allograft biopsy transcript analysis is typically performed by microarray, which lacks spatial resolution. We initiated a systematic program using the NanoString GeoMx® Digital Spatial Profiler (DSP) to map mRNA expression in cells or regions of interest (ROIs) in formalin-fixed paraffin-embedded tissue (FFPE). Here we explore differences in endothelial transcripts in samples with endarteritis in DSA+ chronic antibody mediated rejection/CAMR and DSA- T cell mediated rejection/TCMR in nonhuman primate (NHP) kidney allografts.

Methods: RNAse-free 5um FFPE sections of 2 DSA+ CAMR and 2 DSA- TCMR allograft nephrectomies with endarteritis from Cynomolgus NHPs (Smith 2018) were mounted on slides, hybridized with an 84-gene Immuno-Oncology probe set coupled to photocleavable oligonucleotide tags, and stained with fluorophore-labeled antibodies (DNA, pan-CK, CD45 and CD31). The slides were scanned to the GeoMx® DSP and discrete glomerular, arterial, and tubulointerstitial ROIs (n=48) were defined (Fig 1A-C) and segmented by CD31 expression. ROI tags were quantified on the nCounter® MAX analysis system and analyzed using GeoMx® DSP analysis software.

Results: Differential expression analysis of TCMR arterial endothelial transcripts shows CXCL9 (p=0.003), CXCL10 (p=0.0004), and STAT1 (p=0.02) enrichment, while CAMR arterial endothelial transcripts show higher STAT2 (p=0.02), STAT3 (p=0.0006), and PECAM1 (p=0.003) expression, suggesting DSA-related differences in endothelial response (Fig 1D). Combined glomerular and peritubular capillary (PTC) endothelial transcripts in CAMR show higher ICAM1 (p=0.0006), IFNG (p=0.02), IL6 (p=0.03), and MKI67 (p=0.009). In CAMR, PTC endothelium shows higher HLADQ (p=0.001), HLADRB (p=0.001), CD74 (p=0.004) and BCL2 (p=0.02) than in glomeruli. The CD3/PECAM1 ratio (0.09) demonstrates CD31+ cell-derived transcript selectivity.



Conclusions: Our data reveal endothelial transcript differences in endarteritis related to DSA and diversity of endothelial responses in kidney microvasculature. The GeoMx® DSP allows cell-specific transcript analysis in FFPE and is expected to reveal more insights in the pathogenesis of rejection.

Abstract# 451

Endothelial-to-Myofibroblast Transition (en-mt) and Low Expression of Capillary Vegf Enhance the Development of Interstitial Fibrosis and Glomerulosclerosis Induced by Microvascular Destruction in Antibody-Mediated Rejection (abmr) Patients

B. Ozdemir[1], E. Akcay[1], A. Ok Atilgan[1], M. Haberal[2], *[1]Department of Pathology, Baskent University, Ankara, Turkey, [2]Division of Transplantation, Department of General Surgery, Baskent University, Ankara, Turkey*

Purpose: Interstitial fibrosis (IF) and glomerulosclerosis (GS) are the most important cause of graft loss. Although the rate of microvascular destruction (MVD) is similar in recipients with ABMR, some develop higher IF and GS during follow-up. The exact mechanism of this process is unknown. We aimed to understand why some patients compared to others show higher rates of IF and GS, although they have similar MVD due to ABMR.

Methods: A total of 102 patients with ABMR studied. Biopsies highlighted with CD31 and HLA-DR to determine the mean number of glomerular capillaries (GCs) and peritubular capillaries (PTCs). VEGF expression of GCs and PTCs examined. Capillary expression of α-SMA and F-actin was studied to show the development of En-MT. Follow-up biopsies analyzed for the development of IF and GS.

Results: The mean capillary numbers were 43,4±11,8 and 30,3±8,7 for GCs and PTCs, respectively. The number of PTCs correlated significantly with PTC inflammation (r= -0,56, P<.001), PTC-VEGF expression (r=0,41, P<0,001), En-MT (r= -0,45, P<0.001), proteinuria (r= -0,34, P=.001), the development of IF (r= -0,56, P<0.001), and graft loss (r= -0,57, P<.001). The glomerular capillary loss was also significantly associated with GC inflammation (r= -0,64, P<.001), GC-VEGF expression (r=0,89, P<.001), En-MT (r= -0,61, P<.001), proteinuria (r= -0,89, P<.001), the development of GS (r= -0,70, P<.001), and graft loss (r= -0,44, P<.001). The incidence of proteinuria, the development of IF, the development of GS, and graft loss increased with decreasing PTC and GC VEGF expression and increasing En-MT ratio (p<.001). Although the mean number of PTCs and GCs in some cases was higher than the cutoff point, it was observed that patients with high En-MT and low capillary VEGF expression showed a higher incidence of IF and GS development and, as a result, increased graft loss.

Conclusions: Our findings indicate that monitoring PTC and GC numbers with the presence or absence of En-MT and capillary VEGF expression may become a valuable predictive marker for graft loss. The preservation of capillary endothelium by higher capillary VEGF and lower En-MT can play an essential role in preserving graft survival. Thus the usage of angiogenic factors may become a new approach in the treatment of renal transplantation.

Abstract# 452

Adenovirus-Specific T Cells for Steering of Immunosuppression After Pediatric Kidney Transplantation in the Randomized Controlled Ivist Trial

T. Ahlenstiel-Grunow[1], X. Liu[2], R. Schild[3], J. Oh[3], C. Taylan[4], L. T. Weber[4], H. Staude[5], M. Verboom[6], C. Schröder[7], R. Sabau[7], A. Großhennig[2], L. Pape[1], *[1]Pediatrics II, University Hospital of Essen, Essen, Germany, [2]Institute of Biostatistics, Hannover Medical School, Hannover, Germany, [3]Pediatric Nephrology, University Hospital Hamburg-Eppendorf, Hamburg, Germany, [4]Pediatric Nephrology, University of Colgne, Köln, Germany, [5]Pediatric Nephrology, University Hospital of Rostock, Rostock, Germany, [6]Institute of Transfusion Medicine and Transplant Engineering, Hannover Medical School, Hannover, Germany, [7]Institute for Clinical Pharmacology, Hannover Medical School, Hannover, Germany*

Purpose: Pharmacokinetic monitoring alone is insufficient to estimate the intensity of immunosuppression after pediatric kidney transplantation (Tx). Levels of virus-specific T cells (Tvis) have been shown to identify over-immunosuppression. Our IVIST trial has demonstrated that the additional steering of immunosuppressive therapy by Tvis levels is safe and reduces exposure to immunosuppressive drugs with significantly lower trough levels without increasing the risk of acute rejections.

Methods: In our multicenter, randomized controlled IVIST trial, 64 pediatric kidney recipients (10.8±4.2 years) were randomized 1:1 to a control group with trough level monitoring of immunosuppressants or to an intervention group with additional steering by CD4 Tvis levels against adenovirus (ADV), cytomegalovirus (CMV) and

herpes simplex virus (HSV). CD4 Tvis were quantified by cytokine flow cytometry in 20 visits during the two-year study period. We have analyzed the CD4 Tvis levels and the number of Tvis-based dose adjustments of the immunosuppressive drugs.
Results: At time of Tx ADV-Tvis were detectable in 30/31 patients of the intervention group, CMV-Tvis and HSV-Tvis only in 12/31. No significant ADV DNAemia was found, whereas five primary CMV infections with excessive boost of CMV-Tvis were observed. The mean level of ADV-CD4 Tvis was 1.63 (SD 1.25), 2.03 (SD 1.8), 2.18 (SD 2.51) and 1.97 cells/µl (SD 1.34) 1, 6, 12 and 24 months after Tx. The median number of dose reductions of immunosuppressants based on Tvis <2 cells/µl was 4 (range 0-10) per patient. In the intervention group a total of 125 Tvis-based dose reductions was performed in 28/31 children. 42.4% of the dose reductions were done in the first 6 months, 35.2% between month 7 and 12 and 22.4% in the second year after transplantation.
Conclusions: Under the intensified immunosuppression during the initial post-Tx period low CD4 Tvis levels were observed with subsequent increase after dose reductions of the immunosuppressive therapy. ADV-Tvis are most suitable for immune monitoring considering their high prevalence (even in a pediatric cohort) and stability because of the absence of post-Tx ADV infections. Routine monitoring of CD4 Tvis is predominantly recommendable in the first post-Tx year to prematurely identify over-immunosuppression.

Abstract# 453

A Comparison of Plasmapheresis Methods in the Treatment of Late Antibody Mediated Rejection

Y. Caliskan[1], H. Yazici[2], A. B. Dirim[2], E. Aksoy[2], S. Safak[2], N. Garayeva[2], S. Mirioglu[2], O. Yegit[2], O. A. Oto[2], Y. Ozluk[3], S. Besisik[4], A. Turkmen[2], K. Lentine[1], *[1]Saint Louis University, Saint Louis, MO, [2]Division of Nephrology, Istanbul University, Istanbul, Turkey, [3]Department of Pathology, Istanbul University, Istanbul, Turkey, [4]Division of Hematology, Istanbul University, Istanbul, Turkey*

Purpose: Effective management to prevent allograft loss after late antibody mediated rejection (ABMR) in kidney transplant (KTx) recipients remains a vexing clinical challenge. While plasma exchange (PE) with IVIG has been proposed as a useful treatment, alternatives such as double filtration plasmapheresis (DFPP) and immunoadsorption (IA) represent promising strategies for antibody depletion. We compared graft outcomes associated with use of PE, DFPP and IA in the treatment of late ABMR.
Methods: We performed a retrospective cohort study of 69 KTx recipients [living donor (n=54, 79%), deceased donor (n=14, 21%)] who were diagnosed with biopsy-confirmed "late" (>1 year post-KTx) ABMR at one center and underwent therapeutic plasmapheresis. ABMR was identified at a median of 7.9 (IQR, 3-13) years after KTx. Therapeutic plasmapheresis modalities included: PE (n=31), DFPP (n=22) or IA with protein A (n=16). The primary outcome was allograft loss, defined as return to dialysis or re-transplantation. Multivariate Cox proportional survival analysis was conducted with covariate adjustments to identify predictors of allograft loss.
Results: The study groups were similar regarding age, gender, donor type, donor age and gender, eGFR at ABMR diagnosis and time from KTx to ABMR. Donor specific antibody (DSA) was positive in 84% of PE, 91% of DPFF and 94% of IA groups (p=0.55), and C4d staining in peritubular capillaries was negative in 36%, 23% and 56% (p=0.001) of study groups, respectively. Patients received a total dose of 2 g/kg IVIG with (75%) or without (25%) rituximab (375 mg/m^2). There were no differences regarding IVIG alone or IVIG with rituximab treatment rates in all groups (p=0.16). Adjusted Cox proportional survival analysis with potential confounding factors including age, gender, donor type and C4d staining showed that IA was significantly associated with 67% reduced risk of allograft loss (adjusted hazard ratio $_{0.12}0.33_{0.87}$)(p=0.02). (Fig 1)
Conclusions: While limited by small sample size, this pilot study suggests the efficacy of IA in the treatment of late ABMR. Future prospective and controlled studies should examine the robustness of this observation.

Figure 1. Adjusted Cox proportional survival analysis plots of study groups with potential confounding factors including age, gender, donor type and C4d staining (p=0.02).

Abstract# 454

Investigating the HLA Alloimmune Background of the Histological Changes Suggestive of Antibody-mediated Injury in the Absence of Donor-specific Anti-HLA Antibodies

A. Senev, M. Naesens, *Microbiology, Immunology and Transplantation, KU Leuven, Leuven, Belgium*

Purpose: The histology of antibody-mediated rejection is observed frequently after kidney transplantation, but a significant percentage of the patients do not have detectable donor-specific HLA antibodies ($DSA_{neg}ABMR_h$). Although part of these cases could be related to the presence of non-HLA antibodies, until now, none of the previously suggested non-HLA antibodies are routinely tested in clinical practice for the diagnosis of ABMR. While there is an active interest in non-HLA antibodies' role to $DSA_{neg}ABMR_h$, it remains crucial to exclude the possible contribution of the HLA incompatibility to this phenotype. We aimed to investigate the associations between the HLA molecular mismatches and the occurrence of the $DSA_{neg}ABMR_h$ phenotype.
Methods: All consecutive kidney recipients transplanted at a single center between 2004 and 2013 were eligible for this study. The transplant pairs were genotyped at high-resolution for 11 HLA loci. HLAMatchmaker, PIRCHE-II and HLA-EMMA tools were used to determine the number of HLA molecular mismatches (MM).
Results: Patients with pretransplant donor-specific HLA antibodies were excluded from this study. Of the remaining 798 kidney transplant recipients with available biopsy follow-up, 123 (15.4%) developed $ABMR_h$ in the absence of *de novo* HLA-DSA. In adjusted multivariable Cox analysis, HLA antigen (HR=1.30 per 1; 95%CI 1.15-1.46; p<.0001), HLA allele (HR=1.10 per 1; 95%CI 1.03-1.16; p=0.002) and HLA amino acid mismatches (HR=1.09 per 10; 95%CI 1.03-1.15; p=0.002) were identified as risk factors for developing $DSA_{neg}ABMR_h$. Similarly, all the different HLA molecular mismatches, HLA-EMMA (HR=1.11 per 10; 95%CI 1.04-1.20; p=0.003), eplet MM (HR=1.24 per 10; 95%CI 1.08-1.41; p=0.002) and PIRCHE-II (HR=1.15 per 100; 95%CI 1.05-1.25; p=0.002) associated with $DSA_{neg}ABMR_h$. The subsequent multivariate Cox model, censored for cases with $DSA_{neg}ABMR_h$ and C4d deposition (ABMR according to Banff 2019), confirmed that HLA incompatibility is a risk factor for developing $DSA_{neg}ABMR_h$. Finally, in a sensitivity analysis restricted to anti-HLA antibody-negative patients (n=660), again, all different levels of HLA mismatches were independently associated with the $DSA_{neg}ABMR_h$ rejection phenotype.
Conclusions: HLA mismatches associate with $DSA_{neg}ABMR_h$, also in patients without any sign of circulating HLA antibodies. This indicates that the donor-recipient HLA-incompatibility at least partially explains the development of the histological features of ABMR, in an HLA antibody-independent process.

Abstract# 455

Impact of Machine Perfusion of the Heart on Abdominal Organ Procurement from Donation After Cardiac Death Donors

C. Feizpour, C. Hwang, A. Shubin, J. Shah, L. DeGregoria, S. Hanish, P. Vagefi, M. MacConmara, *Department of Surgery, Division of Surgical Transplantation, University of Texas Southwestern Medical Center, Dallas, TX*

Purpose: Superior preservation with normothermic machine perfusion devices has been demonstrated in thoracic and abdominal allografts, especially DCD donation, where clinical utilization of DCD hearts has become feasible with the use of machine perfusion. The addition of heart donation has increased the complexity of DCD donor procurement. In this study, the impact of heart procurement on organ retrieval activities and abdominal organ yield was examined.

Methods: All potential DCD donors between 2015 and 2020 were identified using the UNOS STARfile. Two donor cohorts were generated based on the presence of Machine Perfusion for the Heart (MPH) group (n=99) or its absence, (Control) group (n=3502). Time from withdrawal to circulatory arrest and circulatory arrest to cross-clamp was calculated and compared between groups. Organ utilization was determined and reasons for discard were examined. Further analysis after propensity score matching for donor age, BMI and cause of death was also done.

Results: MPH procurements had shorter total warm ischemia time (27.0 ± 10.0 vs 29.9 ± 14.0, p=0.04) as well as shorter time from cardiac arrest to aortic cross-clamp (10.6 ± 3.6 vs 12.9 ± 6.5, p=0.001). Liver (53% vs 29%), kidney (87% vs 81%), and pancreas allograft (7% vs 1.1%) utilization were greater in the MPH group. Most discarded livers (79%) in the MPH group were due to anatomic abnormalities, poor flush or biopsy findings. 3 livers discarded for excessive warm ischemia time all had shorter than average arrest to cross-clamp times. After propensity score matching similar shorter procurement times (cardiac arrest to aortic cross-clamp 10.6 ± 3.6 min. vs 13.1 ± 6.3 min, p=0.0007) and enhanced organ utilization (51% vs 34%) were found in the MPH group compared to control.

Conclusions: MPH during DCD procurements does not lead to delays in time from cardiac arrest to aortic cross-clamp. Complex multi-organ procurements, incorporating MPH devices, can be done successfully in DCD donors with increased donor organs.

Abstract# 456

Risk Classification Models for Kidney Graft Failure

M. G. Naik[1], K. Budde[1], D. Telmo Neves[2], *[1]Medical Department, Division of Nephrology and Internal Intensive Care Medicine, Charité, Berlin, Germany, [2]Intelligent Analytics for Massive Data, German Research Center for Artificial Intelligence, Berlin, Germany*

Purpose: Longterm graft survival after kidney transplantation is stagnant over the last decades. An individual risk assessment for graft failure is needed. In our project "TBox", we are developing an end to end data analysis pipeline for that individual risk prediction. Now the focus is on having a set of classification models to detect patients at high risk of graft loss to adapt the follow-up care in our outpatient department.

Methods: All patients transplanted at Charité Mitte between 2000 and 2019 were included. Using raw data (demographics of donor, recipient and transplant) from Charité´s transplant database "TBase" firstly exploratory data analysis was applied continuously to improve data quality and increase insights into the data. Using that curated data two classification models, KNN classification algorithm vs. Random Forest ensemble method for classification were created. The data was split into 75% training 25% test set with averaging the accuracy score and standard deviation for 10 runs in each experiment.

Results: After applying data preprocessing to the selected cohort (N=1570, 62% male recipients, 32% living donation, 51±14years, 18% graft loss), 1483 patients were eligible for data analysis using 84 features (figure 1). The matrices of the models are shown in figure 2. The KNN model achieved an AUC 82.8% (SD 1.7%), with a sensitivity, specificity, accuracy and F1-score of 87.5%, 83.4%, 83.4%, and 18.4%, respectively. The Random Forest model showed an AUC of 97.3% (SD 0.7%) with a sensitivity, specificity, accuracy, and F1-Score are 100%, 96.8%, 97.3%, and 92.6%, respectively.

Conclusions: These first encouraging and promising model results will help to determine graft failure risk and individual decision making for follow-up care after renal transplantation. Next, the data analysis pipeline will be extended for longitudinal and home-monitoring data to create prediction models based on time-aware neural networks to assess the individual risk dynamically, even outside the hospital. Factors to lower the risk for graft loss will be investigated in studies to improve long-term outcomes.

Parameter	Cohort (n=1570)
Recipient	
Female (%)	38.0
Age at transplantation (years)	51.0±14.5
Previous transplant (%)	12.7
Living donation (%)	32.4
Time on dialysis (years)	4.5±3.6
hemodialysis (%)	84.2
Peritonealdialysis (%)	8.8
Preemptive (%)	6.9
Donor	
Age (years)	52.9±14.4
Female (%)	50.5
Transplant	
Delayed graft function (%)	31.4
Cold ischemia time (hours)	8.8±6.1

Abstract# 457

Associations of Mammalian Target of Rapamycin Inhibitors with Post-Transplant Malignancies and All-Cause Mortality: Cause-Specific Competing Risks and Composite Outcomes Analyses

A. H. Santos[1], E. Bueno[1], M. A. Leghrouz[1], W. Xuerong[2], *[1]University of Florida, Gainesville, FL, [2]University of Rhode Island, Kingston, RI*

Purpose: We investigated the outcomes of malignancies and mortality associated with mammalian target of rapamycin inhibitor (MTORI) regimens in adult kidney transplant (KT) recipients (KTRs).

Methods: Using year 2000-2018 SRTR data, we compared the risks of non-melanoma skin cancer (**NMSC**), solid-organ malignancy (**SOM**), and lymphoma associated with 1st transplant-yr. exposure to MTORI regimens [sirolimus or everolimus combined with a calcineurin inhibitor (CNI), mycophenolate, or azathioprine) with or without steroids versus non-MTORI regimens (any CNI, mycophenolate, or azathioprine 2-drug combination) with or without steroids in adult-KTRs.

Results: Among 166,256 adult KTRs studied; 13,056 (7.9%) were on MTORI and 153,200 (92.2%) were on non-MTORI. Except for induction, standardized differences of baseline risk factors were not significant between groups. Over a maximum 5 years of follow-up, the adjusted risks of **NMSC**, **SOM, and lymphoma** were *30% (95% CI=24%-36%); 14% (95% CI=7%-20%)*; and 20% (95% CI=3%-34%) *lower* with MTORI than non-MTORI regimens, respectively. However, the adjusted risk of **all-cause death** (as a cause-specific competing event) was *higher* with MTORI than non-MTORI regimens (**Fig. 1**). The adjusted risks of composite **all-cause death (ACD) or NMSC, ACD or SOM, and ACD or lymphoma** were *8% (95% CI=4%-11%); 12% (95% CI=8%-12%)*; and *17%(13%-21%) higher* with MTORI than non-MTORI regimens, respectively (**Fig. 2**).

Conclusions: MTORI regimens are associated with lower risks of malignancies but higher risk of all-cause death than non-MTORI regimens in adult KTRs. The underlying reasons for these findings need further investigation.

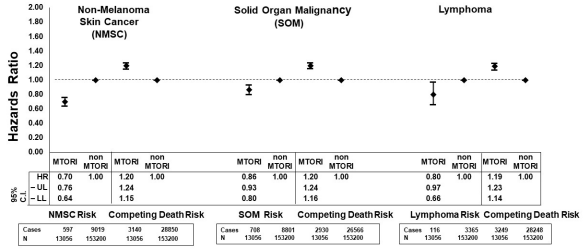

Fig 1. Hazards Ratios of Malignancies and Competing Risk of Death

MTORI: mammalian target of rapamycin inhibitor regimen ; **NMSC**, non-melanoma skin cancer; **SOM**, solid organ malignancy.
Model adjusted for the following covariates: age (18-49, 50-64, or >/-65 years old); sex (male or female); body mass index (<30 kg/m² or >=30 kg/m²); race/ethnicity(Caucasian, African American, Hispanic, or other), primary diagnosis at waitlist enrollment (diabetes mellitus, glomerulonephritis, hypertension, polycystic kidney disease, other or, unknown), duration of pre-transplant dialysis (none, 1-730 days, or >730 days), organ donor type (living, standard deceased donor or, expanded criteria deceased donor), transplant era (2000-2008 or 2009-2018), use of steroids for maintenance immunosuppression (yes or no); re-transplant (yes or no); history of any malignancy pre-transplant (yes or no); and acute rejection from transplant to discharge.

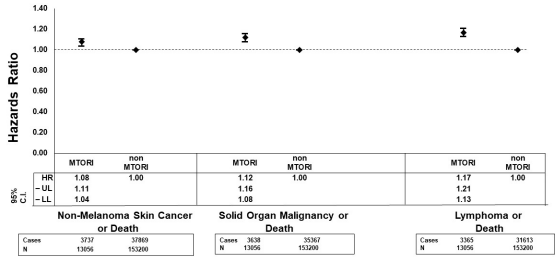

Fig 2. Hazards Ratios, Composite of Malignancy or Death

MTORI: mammalian target of rapamycin inhibitor regimen ; **NMSC**, non-melanoma skin cancer; **SOM**, solid organ malignancy
Model adjusted for the following covariates: age (18-49, 50-64, or >/-65 years old); sex (male or female); body mass index (<30 kg/m² or >=30 kg/m²); race/ethnicity(Caucasian, African American, Hispanic, or other), primary diagnosis at waitlist enrollment (diabetes mellitus, glomerulonephritis, hypertension, polycystic kidney disease, other or, unknown), duration of pre-transplant dialysis (none, 1-730 days, or >730 days), organ donor type (living, standard deceased donor or, expanded criteria deceased donor), transplant era (2000-2008 or 2009-2018), use of steroids for maintenance immunosuppression (yes or no); re-transplant (yes or no); history of any malignancy pre-transplant (yes or no); and acute rejection from transplant to discharge.

Abstract# 458

Feasibility of Normothermic Ex Vivo Kidney Perfusion for Human Kidney Transplantation: First North American Results

L. I. Mazilescu[1], P. Urbanellis[1], J. S. Kim[1], A. Konvalinka[1], T. W. Reichman[1], L. A. Robinson[2], A. Ghanekar[1], M. Selzner[1], *[1]Ajmera Transplant Program, Toronto General Hospital, Toronto, ON, Canada, [2]Department of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada*

Purpose: Normothermic ex vivo kidney perfusion is a novel preservation technique with promising results in porcine models and initial clinical results in one European center. We report the first North American clinical safety and feasibility study with normothermic ex vivo perfusion (NEVKP) in human kidney transplantation.

Methods: Thirteen human kidneys receiving cold anoxic perfusion, plus 1 to 3 hours of NEVKP prior to transplantation, were matched to 39 patients receiving continuous cold anoxic perfusion as preservation method. Perfusion characteristics during NEVKP, post-transplant graft function and 6-month graft survival were assessed.

Results: NEVKP was performed for 149 minutes (44 to 275 min). During perfusion, renal artery flow improved from 326 to 464 ml/min (mean, p = 0.03) corresponding to a decrease of renal artery resistance from 0.27 to 0.18 (mean, p = 0.035). Similarly, the mean pH increased from 7.05 to 7.40 and the average urine output during NEVKP was 16 ml/hr (0 to 105 ml/hr). Glucose and lactate levels were stable during perfusion. After transplantation, kidneys with NEVKP vs. continuous cold anoxic perfusion had similar delayed graft function (31% vs 46%, p = 0.51), and comparable 6-month mean serum creatinine (107 vs 117 micromol/l, p = 0.84) and estimated glomerular filtration rate (55.3 vs 49.4 ml/min/1.73m², p = 0.96). Six-month graft survival was similar between the NEVKP and the cold stored group (92% vs 95%, p = 0.57).

Conclusions: A short period of normothermic ex vivo kidney perfusion after cold storage is safe and feasible in clinical kidney transplantation. NEVKP was not superior to cold storage in this small pilot trial. Prolonged warm perfusion, with a reduction of cold storage, may be required to improve kidney transplant outcomes with NEVKP.

Abstract# 459

Change in Deceased Donor Demographics with Drug Intoxication Deaths: 2010 - 2019

D. Musgrove, D. Zaun, A. Israni, J. Snyder, *SRTR, Minneapolis, MN*

Purpose: To understand the demographic change in deceased donor causes of death associated with drug intoxication, we explored trends over the 10-year period ending in 2019.

Methods: Over the period of interest, we analyzed all deceased donors with a mechanism of death reported as "drug intoxication" on the deceased donor registration form. Donors included were those in whom at least one organ was transplanted and those with at least one organ recovered for transplant. Demographics of interest included age and race as well as geo-referenced information obtained from each donor's home ZIP code (Figure 1). Geo-referenced information included ZIP code-level median income, percent of households with income below the poverty threshold, unemployment rate, and population density.

Results: Overall, the number of donors with drug intoxication deaths grew 374% from 2010 to 2019. Donors aged 17 or younger with drug intoxication saw an 89%

increase, while all adult age groups saw a rise in donations, with those aged 50 or older seeing the sharpest increases, at over 500%. All races had an increase in donors with drug intoxication of over 200%, with Black donors having the largest increase, at over 1100%. Turning to geo-referenced information, donors increased across all income levels by at least 250%, with donors from ZIP codes with a median annual income higher than $75,000 seeing the largest increase, at over 500%. Donors from ZIP codes with the lowest unemployment rates and highest poverty rates saw the largest increase. Lastly, donors from metro areas saw the greatest growth, at over 400%, with donors from micropolitan and rural areas seeing lower but still moderate growth.

Conclusions: In all cases, for both demographic and geo-referenced information, the differences in rates from 2010 to 2019 were statistically significant ($P < 0.05$). Thus, donors who died from drug intoxication over the last decade increased, many of them from vulnerable populations.

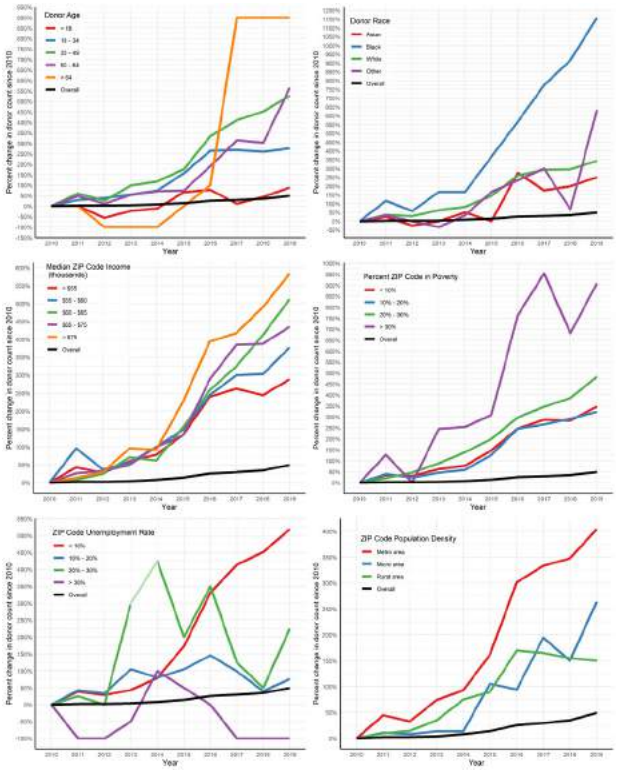

Figure 1. Deceased donor drug intoxication death percent change from 2010 by age, race, and ZIP code median income, percent poverty, unemployment rate, and population density. The black curve denotes the percent change in the overall donor count since 2010.

Abstract# 447

T-Cell Exhaustion in EBV DNAemic Solid Organ Transplant Recipients

S. Kothari, T. Ku, D. Kumar, A. Humar, V. H. Ferreira, *Multi-Organ Transplant Program, University Health Network, Toronto, ON, Canada*

Purpose: In transplant recipients, disease severity after infection with Epstein-Barr virus (EBV) may range from asymptomatic DNAemia to PTLD. Host factors likely play a key role in this including the functionality and number of EBV-specific T-cells. Exhaustion markers expressed on T-cells such as PD-1, TIM-3, CTLA-4 and TOX may also be important indicators of overall functionality and may influence clinical parameters. We assessed expression of these T-cell exhaustion markers in patients with EBV DNAemia.

Methods: We prospectively enrolled consecutive adult organ transplant recipients with EBV DNAemia (>10^3 IU/mL). We performed flow cytometry on isolated PBMCs to simultaneously characterize cell-surface expression of T-cell-associated exhaustion markers (PD-1, CTLA-4, TIM-3 and TOX) on CD4 and CD8 T-cells. Functionality was evaluated by measuring EBV-specific cytokine (IFN-γ, IL-2, TNF-α)-producing T-cells following stimulation with an EBV-infected cell lysate at 10 μg/mL. Viral loads were measured clinically as close as possible to PBMC collection.

Results: We enrolled 25 patients with median age 53 years (range 21-74). Types of transplants included liver (36%), heart (28%), kidney (24%), lung (8%), and small bowel (4%). The median time post-transplant to PBMC sampling was 2.0 years (range 0.2-21). Frequencies of T-cells expressing markers of exhaustion varied in the cohort, with PD-1 expression being highest on CD8 (median 6.2%, range 2.0-54%) and CD4 T-cells (median 10%, range 1.9-18%), followed by TOX, TIM-3 and CTLA-4. Patients were categorized according to high or low proportions of PD-1, TIM-3, CTLA-4 or TOX positive T-cells and compared according to the viral load contemporaneous with PBMC collection. Patients with higher proportions of TOX^+ T-cells had comparatively lower viral loads (p=0.02 for CD4, p=0.03 for CD8). No other associations were observed with respect to exhaustion markers and viral load. In relation to EBV-specific T-cells, those with higher proportions of $PD\text{-}1^+$ or TOX^+ CD4 T-cells had higher frequencies of EBV-specific TNF-α producing CD4 T-cells (p=0.004 for both). Furthermore, patients with higher proportions of $TIM\text{-}3^+$ CD8 T-cells had lower frequencies of polyfunctional CD8 T-cells (p=0.02), defined as those producing TNF-α, IL-2 and IFN-γ. Finally, those with higher proportions of $CTLA\text{-}4^+$ T-cells had lower frequencies of EBV-specific polyfunctional CD4 T-cells (p=0.008) and $TNF\text{-}\alpha^+$ CD8 T-cells (p=0.01).

Conclusions: We observed that many patients with EBV DNAemia exhibited markers of T-cell exhaustion. However, exhaustion markers were not necessarily correlated with negative virologic consequences and in some instances were actually associated with lower viral loads and higher EBV-specific T-cell responses. Future studies will assess the role of T-cell exhaustion as a risk for PTLD development.

Abstract# 448

Development of De Novo Antibody in Renal Transplant Recipients with BK Viremia Managed with Immunosuppression Reduction

R. Hod Dvorai[1], R. Lee[2], P. Muluhngwi[2], M. Raijmakers[3], A. Shetty[2], A. Tambur[2], M. Ison[2], *[1]SUNY Upstate Medical University, Syracuse, NY, [2]Northwestern University, Chicago, IL, [3]University of Santiago, Santiago, Chile*

Purpose: To evaluate development of *de novo* donor specific antibodies (dnDSA) in Renal Transplant Recipients (RTR) with immunosuppression (IS) modulation due to BK viremia (BKV) and the associated risk of antibody mediated rejection (AMR).

Methods: We retrospectively collected data from the NM Enterprise Data Warehouse, primary review of biopsies and HLA antibody testing on all RTR 2007-2017 at our center (n=1911). BK case group included pts who developed BKV >10,000 c/ml or biopsy proven BKV and nephropathy (BKVN), with DSA and biopsy reports through 1 yr post-BK diagnosis. Per protocol, MMF was reduced initially at the direction of the transplant nephrologist. Two controls without BKVN or BKV were matched for each case by gender, donor type and transplant within 1 yr.

Results: 248/1911 RTR (12.9%) had BKV or BKVN. Despite the lower HLA antigen mismatch load (mean=3.5 vs 4.3, p<0.001), the rate of dnDSA was significantly higher in the BK group compared with controls (22.4% vs 12.9%, p=0.004) and the median time from transplant to dnDSA was significantly shorter (298d vs 415d, p<0.001). Interestingly, the incidence of dnDSA was much higher following the diagnosis of BK (16.7% vs 5.7% dnDSA prior to BK diagnosis). There were no significant differences in dnDSA characteristics between BK cases and controls with regards to DSA class, Peak Abs titer, DSA locus etc. AMR was diagnosed in 17/203 (8.4%) biopsied BK and 37/444 (8.3%) biopsied control patients, and the median time from transplant to AMR was lower in the BK group compared with the controls, although the difference did not reach statistical significance (354d vs 463d, p=0.08).

Conclusions: Overall dnDSA rates were higher in BK cases than in control group, with the majority of dnDSA developing following IS reduction for BKVN, and earlier post-transplant. AMR rates were similar between cases and controls, although AMR was more likely to occur earlier post-transplant in the BK cases suggesting a link between IS reduction and the generation of dnDSA.

	RTR Controls (n=443)	BK cases (n=210)	p
dnDSA-, n(%)	357 (80.6)	153 (72.8)

Abstract# 449

De Novo Hepatitis B Infection Following Liver Transplant with Hepatitis B Core Antibody Positive Graft

L. J. Myhre[1], K. D. Watt[2], B. A. Aqel[3], *[1]Pharmacy, Mayo Clinic, Rochester, MN, [2]Gastroenterology/Hepatology, Mayo Clinic, Rochester, MN, [3]Gastroenterology/Hepatology, Mayo Clinic, Phoenix, AZ*

Purpose: The risk of de novo HBV infection in liver transplant recipients of Hepatitis B core antibody (HBcAb) positive donor organs is tempered by availability of antiviral therapy that can be utilized for prophylaxis and HBV vaccinations used to promote Hepatitis B surface antibody (HBsAb) positivity and presumed protection against de novo infection. Unfortunately the duration of prophylaxis necessary and durability of HBsAb immunity to prevent de novo HBV infection remain unknown. The aim of this study is to determine the rate of HBV infection after alteration or discontinuation of prophylactic antiviral therapy.

Methods: This retrospective multi-site observational study spanned January 2014 through November 2020. Transplant recipients ≥ age 18 with a negative HBsAg at time of transplant who received an HBcAb positive graft between 1/1/2014 and 12/31/2019 were screened for inclusion. Patients lost to follow-up or deceased within one year of transplant were excluded. Per institutional protocol, patients with positive HBsAb could discontinue antiviral prophylaxis beyond 1 year post transplant.

Results: This study included 65 patients who received antiviral prophylaxis with lamivudine, entecavir, or tenofovir disoproxil fumarate for at least one year. Patients negative for HBsAb one year following liver transplantation or in whom HBsAb was unavailable (n=43, 66%) continued antiviral therapy. One patient developed de novo HBV despite antiviral prophylaxis after entecavir was switched to lamivudine therapy. Of the patients with positive HBsAb assays one year following liver transplantation (n=22, 34%), ten patients (45%) stopped antiviral prophylaxis. Four of these ten patients (40%) developed de novo HBV infection with HBV DNA positivity between 10-27 months post antiviral discontinuation. Table 1 describes characteristics of the five patients with de novo HBV infection from HBcAb positive donor organs.

Conclusions: De novo hepatitis B infection is an ongoing risk for patients receiving a liver transplant with an HBcAb positive graft, regardless of positive HBsAb assay. Lifelong prophylaxis with antiviral therapy should be strongly recommended.

Superior Post-transplant Clinical Outcomes Using Portable Normothermic Perfusion and Assessment with the Organ Care System (ocs) Liver System: 1-year Outcomes of the Ocs Liver Protect Randomized Controlled Trial

J. Markmann[1], M. Abouljoud[2], M. Ghobrial[3], C. Bhati[4], S. Pelletier[5], J. Magliocca[6], T. Pruett[7], A. Lu[8], M. Rizzari[9], S. Ottmann[10], T. Klair[11], C. Eymard[12], G. Roll[13], G. Reyes[14], S. Black[15], S. Florman[16], S. Mirani[17], C. Marsh[18], G. Schnickel[19], M. Kinkhabwala[20], A. Demetris[21], H. Yeh[22], P. Vagefi[23], M. MacConmara[23], *[1]MGH, Boston, MA, [2]Henry Ford, Detroit, MI, [3]Houston Methodist, Houston, TX, [4]Virginia Commonwealth, Richmond, VA, [5]UVA, Charlottesville, VA, [6]Emory, Atlanta, GA, [7]U. Minnesota, Minneapolis, MN, [8]Tampa General, Tampa, FL, [9]Henry Ford, Detriot, MI, [10]Johns Hopkins, Baltimore, MD, [11]University of Texas HSC, San Antonio, TX, [12]University of Tennessee HSC, Memphis, TN, [13]UCSF, San Francisco, CA, [14]U. Washington, Seattle, WA, [15]Ohio State, Columbus, OH, [16]Mt. Sinai, New York, NY, [17]U. Nebraska, Omaha, NE, [18]Scripps Clinic, San Diego, CA, [19]U. San Diego, San Diego, CA, [20]Montefiore, New York, MA, [21]UPMC, Pittsburgh, PA, [22]Massachusetts General Hospital, Boston, MA, [23]UT Southwestern, Dallas, TX*

Purpose: The OCS Liver PROTECT Trial was the first U.S. randomized controlled trial for liver perfusion and was designed to evaluate the impact of portable warm machine perfusion on clinical outcomes and donor liver utilization.

Methods: PROTECT compared outcomes in recipients of livers preserved using the liver Organ Care System (OCS) or ischemic cold storage (ICS Control). Primary effectiveness endpoint was incidence of early allograft dysfunction (EAD). Other clinical endpoints included overall survival and incidence of ischemic biliary complications (IBC) at 6 and 12 months. Primary safety endpoint was average number of liver graft related SAEs (LGRSAEs).

Results: 300 patients were enrolled (153 OCS and 147 Control). OCS use resulted in significant reduction of EAD (OCS 17.3% vs. Control 30.5% p=0.009), attenuation of reperfusion syndrome in the recipient, and reduction in the severity of reperfusion injury on allograft histology. Importantly, the presence of EAD conferred a

significantly higher risk of graft failure (log-rank 0.0002). OCS was also associated with significant reduction of IBC at 6 and 12-months post-transplant (6 months- OCS 1.3% vs. Control 8.5% p=0.004; 12 months - OCS 2.6% vs Control 9.9 p=0.010). PROTECT's safety endpoint was met with low mean LGRSAEs (OCS 0.046 to Control 0.075, non-inferiority p<0.0001). OCS preservation resulted in significantly higher utilization of DCD donor livers for transplantation (OCS 45.9% vs. Control 24.5% p= 0.020). Overall patient and graft survival were similar between the groups.
Conclusions: To our knowledge, PROTECT results represent the first report of an intervention simultaneously reducing both EAD and IBC post liver transplantation. In addition, OCS resulted in significantly increased utilization of DCD donors. We conclude that OCS Liver preservation is associated with superior post-transplant outcomes and increased donor liver utilization for transplantation.

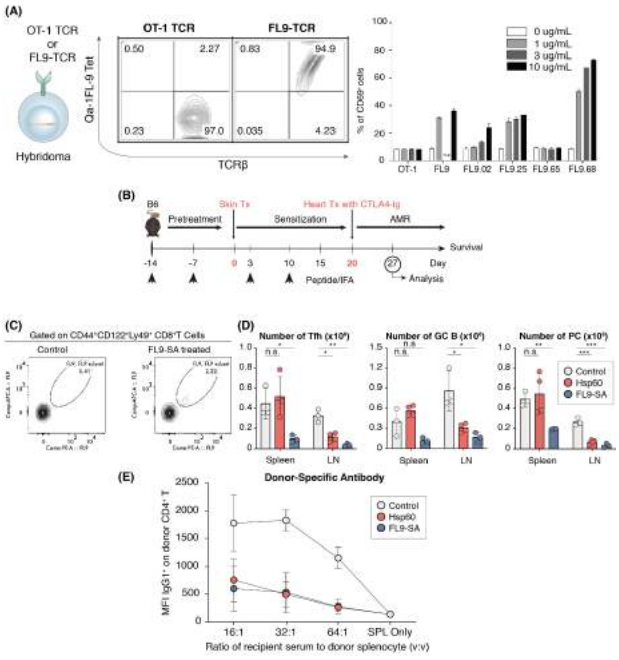
Abstract# 298

Novel Discovery of Super-antigen That Mobilize Regulatory Cd8 T Cells Inhibits Donor-specific Antibody and Protects Heart Allografts from Antibody-mediated Rejection

J. Y. Choi[1], H. Nakagawa[2], Z. Solhjou[1], K. Yatim[1], H. Zhang[3], P. Patel[3], M. Tawfeek Mohammed[3], L. Riella[4], H. Kim[2], H. Cantor[2], J. Azzi[1], *[1]Brigham and Women's Hospital/Harvard Medical School, Boston, MA, [2]Dana Farber Cancer Institute/Harvard Medical School, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Massachusetts General Hospital/ Harvard Medical School, Boston, MA*

Purpose: Antibody-mediated rejection (AMR) is a critical barrier to long-term allograft survival. We showed that Qa-1 (HLA-E in humans) restricted $CD8^+$ T cells (CD8 Treg) play an essential role in controlling humoral immunity by killing alloreactive $CD4^+$ T cells, especially follicular helper T cells (Tfh) that upregulate Qa-1 under immunologic stress conditions. We previously showed that interruption of $CD8^+$ T cell receptor (TCR) binding to Qa-1 unleashes Tfh proliferation and leads to severe AMR in murine cardiac transplantation. In this study, we identified stress peptides (SPs) presented by Qa-1, modified one of these peptides to engineer a super-agonist (SA), and tested the efficacy of SPs in mobilizing CD8 Treg. Finally, we examined if SPs subdue allo-sensitization and protect heart grafts from AMR.
Methods: Based on previous mass-spectrometry studies, we selected two SPs - FL9 and Hsp60p216 - that associate with Qa-1 under immunologic stress conditions. We then sorted FL9-Qa-1 tetramer binding CD8 Tregs, sequenced their TCR, and expressed on hybridoma. We also generated a library of modified FL9 sequences and compared their antigenicity using the TCR engineered hybridoma. After selecting FL9-SA, we performed BALB/c to B6 skin transplantation with or without Hsp60p216 and FL9-SA, followed by heart transplantation to induce AMR.
Results: We successfully generated FL9-SA using our TCR engineered hybridoma system. Immunization with SPs significantly expanded SP-Qa-1 tetramer binding CD8 Treg. Compared to the control group, hosts treated with SPs during sensitization showed a significant reduction in Tfh and mature B cells including plasma cells. FL9-SA was substantially more efficacious than Hsp60p216. More importantly, donor-specific antibody (DSA) was significantly decreased in SP-treated groups, resulting in protection of heart allografts.
Conclusions: Eliciting CD8 Treg response with Qa-1-associating SPs subdue germinal center reaction and DSA formation. Especially, the super-agonist that we generated showed superior biological efficacy in mobilizing CD8 Treg. Exploiting the mechanism of CD8 Treg through the study of Qa-1-associating peptides may offer a novel strategy to suppress AMR, which lacks effective therapeutic options.



(A) Generation of FL9 superagnoist. *Left:* Hybridoma was engineered to express T cell receptor (TCR) restricted to FL9-Qa-1 while OT-1 TCR used as a control. FL9-TCR expressing hybridoma but not OT-1-TCR expressing hybridoma binds to FL9-Qa-1 tetramer. *Right:* Library of modified FL9 peptides were generated and tested their capacity to activate (CD69) FL9-TCR hybridoma. FL9-68 was selected as a FL9-super-agnoist (FL9-SA)
(B) Schematics of skin sensitization induced cardiac AMR model.
(C) Representative layouts of FL9-Qa-1 restricted CD8 Treg. Hosts immunized with FL9 show 8-fold expansion of FL9-Qa-1 tetramer binding CD8 Treg (CD44+CD122+Ly49+ CD8+ T)
(D) Immunophenotype of spleen and draining lymph nodes. *Tfh: follicular helper T cells (PD-1+CXCR5+CD4+ T); GC B: Germinal Center B Cells (GL-7+FAS+B220+); PC: Plasma Cells (CD138+B220); *:P<0.05; **:P<0.01; ***:P<0.001; n.s: not significant*
(E) Donor-Specific Antibody Assay. x axis indicates volume-to volume ratio of recipient serum to donor splenocyte diluted in PBS at 10^6 cells/mL.

Abstract# 299

Extreme Phenotype Sampling and Next Generation Sequencing to Identify Genetic Variants Associated with Tacrolimus Metabolism in African American Kidney Transplant Recipients

C. R. Dorr[1], B. Guo[2], B. Wu[2], J. Abrahante[2], D. Schladt[3], R. Remmel[2], W. Guan[2], A. Muthusamy[3], G. Onyeaghala[3], N. Pankratz[2], A. Matas[2], R. Mannon[4], W. Oetting[2], P. Jacobson[2], A. K. Israni[3], *[1]Hennepin Healthcare Research Institute, Minneapolis, MN, [2]University of Minnesota, Minneapolis, MN, [3]Nephrology, Hennepin Healthcare Research Institute, Minneapolis, MN, [4]University of Nebraska Medical Center, Omaha, NE*

Purpose: Tacrolimus (TAC) pharmacogenomics studies identified common genetic variants that alter TAC troughs suggesting strategic dosing for specific populations. Common variants and clinical factors explain ~50% of TAC trough variability in African American (AA) kidney transplant recipients. We hypothesized low-frequency variants may explain the remaining variability that may lead to improved dosing strategies for AAs.
Methods: We repeated an Extreme Phenotype Sampling (EPS) model and expanded Next Generation Sequencing (NGS) (doi: 10.1038/s41397-018-0063-z) with substantially more samples to identify genetic variants associated with TAC troughs in AAs. AA subjects from the DeKAF Genomics and GEN03 cohorts were combined (n = 695). The study evaluated TAC troughs in the first 6 months post-transplant. EPS included 77 subjects with the highest, and 77 subjects with the lowest, dose-normalized TAC troughs after adjusting for clinical factors and CYP3A5 *3, *6, *7 variants. The NGS spanned 5.3 mB of 63 TAC related metabolism and pharmacodynamics genes, including 20 kB of flanking sequences. Variant call file (VCF) was created, SNPeff was used to assess the VCF data and Variant Effect Predictor (VEP) predicted protein functions by SIFT or Polyphen. Identified single variants were analyzed by single SNP, gene-based and subset analyses association with TAC troughs.
Results: SNPeff identified 41,510 variants classified as 48% intronic, 24% intergenic, 1.3% exonic or 26.7% other. The analysis identified 6 SNPs, mostly in *PPP3CA*, that were associated with TAC troughs when controlling the false discovery rate at

0.05 (Table 1a). SNP set analysis of rare SNPs predicted to be deleterious by SIFT and probably damaging by Polyphen were associated with TAC troughs (p=0.0017, Table 1b). The missense variant rs72557946 in *POR* was also associated with TAC troughs (p=0.008).

Conclusions: We identified novel variants associated with TAC troughs in AAs. Most of variants with TAC association were in *PPP3CA* which activates T-cells via NFATc and interacts with TAC. Functional analysis of these SNPs will be done in cell culture. Identification of additional SNPs which impact TAC troughs may lead to improved treatment strategies for AAs.

Abstract# 300

Role of Ferroptosis Inhibitors in Mitigating Ischemia-Reperfusion Injury in Marginal Livers Using a Novel Protect Model

M. D. Nazzal, J. Van Nispen, A. Armstrong, V. Murali, E. Song, M. Voigt, A. Samaddar, E. Madsen, C. Manithody, J. Krebs, D. Blackall, D. Carpenter, C. Varma, J. Teckman, A. Jain, *Saint Louis University, Saint Louis, MO*

Purpose: The discard rate of deceased donor livers (DDL) remains high at nearly 9% and incudes livers that are steatotic, old in age, and from donation after cardiac death. The major challenge with marginal DDL (MDL) is severe Ischemia reperfusion injury (IRI) which clinically leads to primary non-function or early graft dysfunction with increased recipient morbidity and mortality. We proposed that reduction of ferroptosis, a form of regulated cell death related to an increase in intracytoplasmic iron, would reduce IRI in MDL. We tested our theory using our previously described PROTECT model (Perfusion Regulated Organ Therapeutics with Enhanced Controlled Testing) using normothermic perfusion of 2 split liver lobes simultaneously with one lobe acting as an internal control for the other.

Methods: Discarded MDL were split into right and left lobes and perfused using the PROTECT pump. One lobe was treated with deferoxamine (DM) (0.6mmol/L) and the other acted as an internal control. We compared intracellular iron content, biochemical measures, and pre-ferroptotic genes expression between the lobes.

Results: Both lobes were perfused for 3 hours. Alanine aminotransferase (ALT) and aspartate aminotransferase (AST) decreased in the DM treated lobe throughout the experiment, while ALT (U/L) and AST (U/L) rose in the control lobe (ALT DM lobe$_{final\ -\ initial}$ = -405, ALT Control lobe$_{final\ -\ initial}$ = 586; AST DM lobe$_{final\ -\ initial}$ = -380, AST Control lobe$_{final\ -\ initial}$ = 617) (Figure 1A). Similarly pro-ferroptotic genes, including HO-1 (2.74 vs 6.93), HIF1α (2.60 vs 8.67), and RPL8 (0.72 vs 1.52) fold change expressions were all decreased in the DM lobe compared to the control lobe. The expressions of these genes were additionally compared to a sample taken from a healthy liver (Figure 1B). Lastly, Prussian Blue iron staining and intensity quantification showed a marked decrease in iron quantity in the DM lobe compared to the control lobe ($288 \pm 18_E^{-3}$ vs $329 \pm 13_E^{-3}$; p = 0.036) (Figure 1C and D).

Conclusions: By administering DM, we reduced the content of iron within hepatocytes, thus reducing ferroptosis as shown by the decreased expression of pro-ferroptotic genes (HO-1, HIF1α, RPL8). In addition, we observed improvement in ALT and AST in the lobe that was treated with DM. Our data suggests that reducing ferroptosis helps to mitigate IRI. This approach could serve as the basis for a clinical trial using DM to reduce IRI in MDL; thus, increasing the utility of such organs.

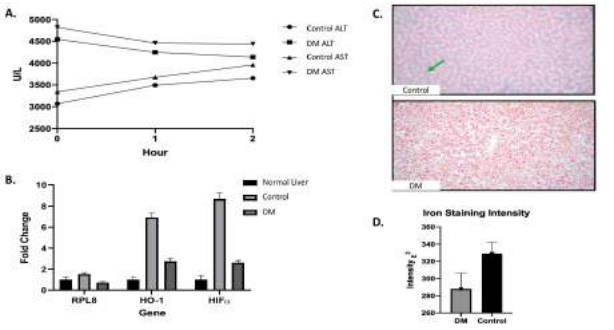

Figure 1: A. Serum ALT (U/L) and AST (U/L) rose throughout the experiment in the control lobe while ALT and AST decreased throughout the experiment in the DM lobe. B. RPL8, HO-1, and HIFα expression was compared between a healthy liver biopsy, the control lobe, and the DM lobe. RPL8, HO-1, and HIFα expression was increased in the control lobe, while the expression of these genes was reduced in the DM lobe. C. Prussian Blue staining was performed to assess for iron in the control lobe and the DM lobe. The green arrow points to a demonstrative accumulation of iron. D. ImageJ intensity quantification revealed that iron accumulation was significantly reduced in the DM lobe compared with the control lobe.

Abstract# 301

Lymphotoxin Beta Receptor Regulates Treg Migration and Suppression by Modulating Draining Lymphatic Structure

V. Saxena[1], W. Piao[1], L. Li[1], M. W. Shirkey[1], J. Iyyathurai[1], R. Lakhan[1], R. Abdi[2], J. Bromberg[1], *[1]U Maryland, Baltimore, MD, [2]Harvard U, Boston, MA*

Purpose: Regulatory T cells (Treg) must migrate from tissues via lymphatic vessels (LV) to the draining lymph node (dLN) to induce tolerance. During migration, Treg lymphotoxin alpha (LTα) stimulates lymphotoxin beta-receptor (LTβR) signaling on lymphatic endothelial cells (LEC) lining the LV and dLN. We hypothesized that LEC LTβR regulates Treg migration and suppression by modulating LN structure and function.

Methods: LTβR$^{fl/fl}$ mice were crossed with Prox1-Cre-ER^{T2} mice to generate knock out (KO) mice, which lack LTβR expression in LEC after tamoxifen treatment. Littermate Prox1-Cre-ER$^{T2-/-}$LTβR$^{fl/fl}$ wild type (WT) were used as controls. Using flow cytometry, immunohistochemistry and in vivo and transwell based in vitro migration assays, the effects of LTβR depletion on Treg lymphatic migration and LN structures were analyzed.

Results: In KO 10 days after tamoxifen treatment, LTβR expression was markedly reduced specifically on LEC, yet maintained in fibroblastic reticular cells and blood vessel endothelial cells. This selective inhibition resulted in poor Treg migration in KO mice from tissues to draining LN. These effects were confirmed in an islet allograft model, where Treg transferred into the islet graft migrated poorly to the draining LN in KO mice, resulting in reduced allograft survival from 25d to 13d (p<.03). Migrating Treg maintained high Foxp3 expression, while non-migrating Treg lost Foxp3 and CD25 expression to become exTreg. LTβR depletion did not affect LN architecture, but reduced accumulation of Foxp3+ cells in LN cortical ridge, the LN microdomain important for Treg induction. LTβR depletion modulated expression of selected chemokines important for T cell migration. It decreased expression of CXCL12 and CCL21, while expression of VCAM-1, ICAM-1, and CCL19 remained similar to WT. LTβR depletion also reduced expression of non-canonical NFκB kinase (NIK) and the chemotactic lipid sphingosine-1-phosphate (S1P) in LEC. In a transwell based Treg-LEC co-culture assay, non-migrating Treg became exTreg due to both non-canonical NIK and canonical NFκB LTβR signaling in LEC.

Conclusions: LTβR depletion from LEC inhibited Treg migration from tissues to LN and reduced accumulation of Foxp3+ Treg in the LN. Non-migrating Treg became exTreg via NFκB LTβR signaling in LEC and correlated with poor islet allograft survival. LTβR is identified as a key regulator of Treg migration and subsequently suppressive function for ensuring graft survival.

Abstract# 302

CD47-Mediated Gli1/Notch1 Signaling is a Key Regulator of Mesenchymal Stem Cell Immunomodulation in Liver Inflammatory Injury

D. Xu, M. Sheng, Y. Lin, Y. Tian, Y. Zhan, C. Li, A. J. Coito, R. W. Busuttil, D. G. Farmer, J. W. Kupiec-Weglinski, B. Ke, *Surgery, Dumont - UCLA Transplant Center, Los Angeles, CA*

Purpose: *The* CD47-signal regulatory protein alpha (SIRPα) signaling pathway plays important roles in immune homeostasis and tissue inflammatory response. Gli1, the downstream effector of the Hedgehog pathway has been shown to regulate immune cell activation and inflammatory response. However, it remains unknown as to whether and how the CD47-SIRPα signaling may influence the Hedgehog pathway to control innate immune response in mesenchymal stem cell (MSC)-mediated immune regulation during liver inflammatory injury. This study investigated the roles and molecular mechanisms of MSC CD47-mediated Gli1/Notch1 signaling in ischemia/reperfusion-triggered liver inflammation.

Methods: Myeloid-specific SMO or Notch1 knockout ($SMO^{M\text{-}KO}$ and $Notch1^{M\text{-}KO}$) and floxed SMO or Notch1 ($SMO^{FL/FL}$ and $Notch1^{FL/FL}$) mice (n=6/group) were i.v. injected with bone marrow-derived MSCs or genetically modified MSCs ($1x10^6$ cells in PBS/mouse) 24h prior to surgical procedure, and then subjected to 90 min partial liver warm ischemia followed by 6 h of reperfusion. In parallel *in vitro* study, MSCs were transfected with CRISPR/Cas9-mediated CD47 knockout (KO) or control vector, and then co-cultured with bone marrow-derived macrophages (BMMs) followed by LPS (100 ng/ml) stimulation.

Results: *Adoptive transfer of MSCs* increased CD47 expression and ameliorated liver IRI. However, deletion of CD47 in MSCs exacerbated IR-induced hepatocellular damage, with increased serum ALT levels, macrophage/neutrophil infiltration, and pro-inflammatory mediators. MSC treatment augmented SIRPα, Hedgehog/SMO/Gli1, and Notch1 intracellular domain (NICD) whereas CD47-deficient MSC treatment reduced these gene expressions in IR-stressed livers. Moreover, disruption of myeloid SMO or Notch1 increased IR-triggered liver inflammation with diminished Gli1 and NICD but enhanced NEK7 and NLRP3 activation in MSC-transferred mice. Using MSC/macrophage co-culture system, we found that MSC CD47 and macrophage SIRPα expression were increased after LPS stimulation. The CD47-SIRPα interaction increased macrophage Gli1 and NICD nuclear translocation whereby NICD interacted with Gli1 and regulated its target gene Dvl2, which in turn inhibited NEK7/NLRP3 activity.

Conclusions: The CD47-SIRPα signaling activates the Hedgehog/SMO/Gli1 pathway, which controls NEK7/NLRP3 activity through a direct interaction between Gli1 and NICD. NICD is a novel coactivator of Gli1, and the target gene Dvl2 regulated by the NICD-Gli1 complex is crucial for the modulation of NLRP3-driven inflammatory response in MSC-mediated immune regulation. Our findings provide novel potential therapeutic targets in MSC-based immunotherapy of sterile inflammatory liver injury.

Abstract# 303

Double Negative T Cells Mediate Cd39-Dependent Protection in Hepatic Ischemia and Reperfusion Injury

H. Jin, M. Li, C. Zhang, G. Sun, D. Zhang, *Beijing Key Laboratory of Tolerance Induction and Organ Protection in Transplantation, Beijing Friendship Hospital, Capital Medical University, Beijing, China*

Purpose: Hepatic ischemia and reperfusion injury (HIRI) is a significant cause of morbidity and mortality following liver transplantation and major hepatic resections. Double negative T cells (DNT) are unique regulatory T cells which are discovered in recent decades.We have demonstrated that DNT significantly inhibit allo- or auto-immune responses mainly through perforin/granzyme B pathway. However, whether other mechanisms are involved in the immune regulation of DNT and the potential application of DNT in HIRI are still unknow.

Methods: WT or CD39 deficient DNT were adoptively transferred before surgery, and then the mouse model of partial (70%) warm HIRI was established. *In vitro*, WT or CD39 deficient DNT were cocultured with neutrophils with or without ATP stimulation. Transcriptome sequencing of ATP treated WT or CD39 deficient DNT were analyzed.

Results: In this study, we found DNT highly expressed CD39, a cell surface enzyme hydrolyzing extracellular ATP. Adoptively transferring with wild type (WT) but not CD39 deficient DNT significantly inhibited TNF-α and IL-1β secretion of liver infiltrated neutrophils, decreased neutrophil extracellular traps (NETs) generation and increased neutrophil apoptosis in warm HIRI in both C57BL/6 and T cell deficient B6.*Rag2/IL2rc* KO mice. Which contributed to markedly alleviated liver injury, as shown by lowered levels of serum ALT and reduced hepatocellular necrosis. Mechanistically, compared with WT DNT, CD39 deficient DNT were unable to hydrolyze extracellular cytotoxic ATP and became apoptotic under ATP stimulation. Transcriptome sequencing analysis suggested that ATP treated CD39 KO DNT had reduced expression of cell activation, proliferation and chemotaxis related genes than WT DNT. However, no differences of *Prf1* or *Gzmb* gene expression were observed between groups. Furthermore, the level of extracellular immunosuppressive molecule, adenosine, was significantly higher in the culture of ATP treated WT DNT compared with that of CD39 deficient DNT. ATP-treated WT DNT but not CD39 deficient DNT significantly increased neutrophil apoptosis and inhibited inflammatory mediators secreted by neutrophils *in vitro*, suggesting that CD39 expressed by DNT might drive a shift from an ATP driven proinflammatory environment to an anti-inflammatory milieu induced by adenosine.

Conclusions: In conclusion, our study reveals a new intrinsic mechanism that CD39 is crucial for DNT homeostasis and immunosuppressive function. These data support the concept and the feasibility of potentially utilizing this novel cell therapy for the prevention of HIRI during liver transplantation or hepatic surgery.

Abstract# 304

The Gut Microbiotainduces Local and Systemic Immune Modulation

V. Saxena, R. Lakhan, J. Iyyathurai, W. Piao, L. Li, T. Zhang, M. W. Shirkey, B. Ma, E. F. Mongodin, J. Bromberg, *U Maryland, Baltimore, MD*

Purpose: We previously demonstrated that gut microbiome alterations, through fecal microbiota transfer (FMT) or single bacteria transfer, had specific immune effects for cardiac allograft outcome. The present study aimed to characterize immune stimulatory or suppressive effects of gut bacteria on cells and structures of the host immune system.

Methods: Antibiotic-pretreated mice received vascularized cardiac grafts and tacrolimus. Mice were gavaged with *Bifidobacterium pseudolongum* (*Bifido*), a dominant gut member in immuno-suppressed hosts, or *Desulfovibrio desulfuricans* (*Desulfo*), abundant in colitis. Longitudinal characterization of the mouse gut microbiota was performed using 16S rRNA gene sequencing. The effect of shifts in microbiota on immune responses was assessed with immunohistochemistry and flow cytometry of intestinal segments and lymph nodes (LN). Bone marrow derived dendritic cells (BMDC), peritoneal macrophages (MΦ), and B cells were stimulated with bacteria or isolated *Bifido* exopolysaccharides (EPS), and cytokine responses measured by ELISA and activation markers by flow cytometry.

Results: *Bifido* decreased graft inflammation and fibrosis and prolonged allograft survival. *Desulfo* resulted in poor histology and reduced graft survival. *Bifido* significantly (p=0.016) increased LN $Foxp3^+$ CD4 regulatory T cells (Treg) and decreased (p=0.002) LN and spleen activated $CD44^{hi}CD69^+$ CD4 effector T cells (Teff) compared to *Desulfo*. Intestinal segments and mesenteric LN, but not peripheral LN, showed increases in $Foxp3^+$ Treg cells, $F4/80^+$ MΦ and $CD11c^+$ DC early after *Bifido* treatment but not *Desulfo* treatment. These bacteria also profoundly altered the structure of the LN stromal laminin fibers to create suppressive or inflammatory niches, with increased laminin α4:α5 ratios in the *Bifido* group and decreased ratios in the *Desulfo* group. Stimulation of myeloid cells with EPS did not affect expression of CD40, CD80, CD86, or MHC II, but prevented lipopolysaccharide (LPS) induced TNFα and IL-6 expression by BMDC. Stimulation of BMDC with *Bifido* cells or EPS induced the expression of the anti-inflammatory cytokines IL-10 and CCL19, but induced lesser amounts of the pro-inflammatory cytokines TNFα and IL-6. Microbiota characterization using 16S RNA gene sequencing and Principal Coordinate Analysis of Jensen-Shannon divergence showed gut microbiome profiles clustered by study group over time.

Conclusions: These results demonstrate immunomodulatory properties of gut microbiota, selected bacterial strains, and specific bacterial surface structural component. They have specific effects on myeloid cells and LN stromal fibers in different immune compartments. Characterization of the microbiota in organ transplantation provides novel insights into functional pathways involved in modulating inflammation and immunity.

Abstract# 305

Single Cell Rna-Sequencing of Urinary Cells and Defining the Immune Landscape of Rejection in Human Kidney Allografts

T. Muthukumar[1], H. Yang[1], A. Belkadi[2], G. Thareja[2], C. Li[1], C. Snopkowski[1], K. Chen[1], T. Salinas[1], M. Lubetzky[1], J. Lee[1], D. Dadhania[1], K. Suhre[2], M. Suthanthiran[1], *[1]Nephrology, NY Presbyterian- Weill Cornell Medical College, New York, NY, [2]Physiology and Biophysics, Weill Cornell Medicine-Qatar, Doha, Qatar*

Purpose: Transcriptome-based clustering of urinary cells in kidney transplant recipients may help identify cell-type specific injury and develop cell-type specific biomarkers for the noninvasive assessment of human kidney allografts.

Methods: Single cell RNA-sequencing (scRNA-seq) was performed on urinary cells obtained at the time of allograft biopsy from kidney transplant recipients with biopsies classified as acute T cell mediated rejection [TCMR], chronic active antibody mediated rejection [ABMR], or normal/no rejection [Normal]. Droplet-based 10x Chromium platform (10x Genomics) was used to capture the individual urinary cells in emulsion, followed by cDNA synthesis, sequencing, and data analysis.

Results: We obtained 3947 high quality cellular transcriptomes from the urine samples matched to TCMR biopsy, ABMR biopsy, or Normal biopsy. Cell-type assignment following uniform manifold approximation and projection (UMAP)-based visualization of urinary single cells from the patient with Normal/No-Rejection biopsy (Panel A), acute TCMR biopsy (Panel B), or ABMR biopsy (Panel C) are shown in Figure 1. Urine samples matched to the TCMR biopsy was exemplified by increased macrophages, dendritic cells, T cells, and NK cells whereas renal tubular epithelial cells were dominant in urine matched to normal biopsy. Further resolution of immune cells revealed sub-clusters of dendritic cells (Figure 2).

Conclusions: We have demonstrated the feasibility of transcriptome analysis of individual cells in urine samples matched to human kidney allograft biopsies. To our knowledge, this is the first report of urinary cell scRNA-seq in kidney transplant recipients. Our study has deciphered the complex cellular landscape of kidney allograft rejection and provides opportunity to interrogate molecular events at a hitherto unattained level of resolution.

Abstract# 306

Gm2a: A Novel Regulatory Pathway Controlling Alloimmunity

K. M. Baecher[1], P. S. Heeger[2], P. Cravedi[2], M. Fribourg[2], M. L. Ford[1], *[1]Department of Surgery, Emory University, Atlanta, GA, [2]Mount Sinai School of Medicine, New York, NY*

Purpose: In recently published studies we discovered that the inhibitory receptor FcγRIIB regulates $CD8^+$ T cell alloimmunity in a cell-autonomous fashion, and that increased expression of *FCGR2B* was associated with freedom from rejection following tacrolimus withdrawal in the CTOT-09 clinical trial. These observations led us to query specific pathways that are upregulated in FcγRIIB$^+$ T cells that promote allograft survival.

Methods: We cross-referenced the list of ~1009 differentially expressed genes (DEG) in FcγRIIB$^+$ vs. Fc RIIB$^-$ $CD8^+$ murine T cells with the list of transcripts that were differentially expressed at baseline (before Tacrolimus withdrawal) in patients who were stable vs. rejected off immunosuppression in the CTOT-09 cohort. In subsequent mechanistic studies, *Gm2a*$^{-/-}$ mice and WT littermate controls received BALB/c skin grafts and alloimmune responses were assessed via flow cytometry.

Results: Analysis of Affymetrix gene array data revealed that 3 genes upregulated in CTOT-09 stable patients (*Gm2a, Cpa3 and Skap2*) were also differentially expressed in RNA-Seq datasets comparing transcript expression in FcγRIIB$^+$ T cells vs. FcγRIIB$^-$ $CD8^+$ T cells. To determine whether these differences were associated with the $CD8^+$ cellular immune response to transplantation, CellCODE deconvolution analysis was performed to identify the cell lineages associated with the differential expression between stable and rejectors. These data revealed that the difference in *Gm2a,* an essential cofactor associated with sphingolipid processing, demonstrated the strongest association with $CD8^+$ T cells. To determine if Gm2a plays a mechanistic role in suppressing alloimmune responses in vivo, we assessed the magnitude and functionality of alloreactive T cell responses in WT vs *Gm2a*$^{-/-}$ mice. While frequencies of $CD44^{hi}$ cells in naïve WT vs. *Gm2a*$^{-/-}$ mice were not different, analysis of splenocytes at day 10 post-transplant revealed a significant increase in the absolute number of $CD44^{hi}$ activated effectors in both the $CD4^+$ and $CD8^+$ T cell compartments in *Gm2a*$^{-/-}$ animals relative to WT littermate controls. Moreover, *Gm2a*$^{-/-}$ mice also demonstrated increased frequencies of TNF-expressing $CD8^+$ T cells, decreased frequencies of IL-2-expressing $CD8^+$ T cells, and fewer NKT cells relative to WT controls.

Conclusions: Taken together, our results from human renal transplant patients and experimental mouse models suggest that *Gm2a* may be a critical, as-yet unrecognized, immunologic mediator of transplant tolerance.

Abstract# 307

Nanoparticle Mediated Drug Delivery for Lung Transplantation

P. M. Patel[1], S. Jung[2], C. L. Miller[1], J. M. O[1], T. Costa[1], A. Dehnadi[1], I. Hanekamp[1], X. F. Li[2], L. Jiang[2], H. Ichimura[2], A. Azimzadeh[1], J. C. Madsen[3], R. Abdi[2], *[1]Surgery, Center for Transplantation Sciences, Massachusetts General Hospital/Harvard Medical School, Boston, MA, [2]Medicine, Transplant Research Center, Brigham and Women's Hospital, Boston, MA, [3]Surgery, Center for Transplantation Sciences, Division of Cardiac Surgery, Massachusetts General Hospital/Harvard Medical School, Boston, MA*

Purpose: Severe primary graft dysfunction (PGD) affects 30% of lung transplant patients. Pulmonary alveolar macrophages play a significant role in lung PGD, but systemic immunotherapy is inadequate in suppressing them. We explored using nanoparticles (NP) as a means of direct allograft immunosuppression delivery.

Methods: We encapsulated Alexa 594 dye and anti-IL6 receptor monoclonal antibody in poly (lactic-co-glycolic acid) NPs via double emulsion (anti-IL6R-Alexa 594 NP). The lung from one cynomolgus macaque was procured then underwent infusion of lung preservation solution mixed with nanoparticles via direct pulmonary artery cannulation. Samples pre- and post-NP infusion were taken and stained using immunofluorescence techniques. Tissues were stained with antibodies against CD163, vWF, CD11b, CDC11c, HLADR$^+$, CD3, and CD20.

Results: Hydrodynamic size of anti-IL6R-Alexa594 NP was 107 ± 14 nm (polydispersity index: 0.25), transmission electron microscopy size was 98 ± 8.1 nm, and zeta-potential was -3.1 ± 1.2 mV. We confirmed loading efficiency of anti-IL6R-mAb in NP as 23.1 ± 3.8% using bicinchoninic assay. Anti-IL6R-Alexa594 NP showed 50% of drug elution by 4.6 days and 75% of drug elution by 13 days **.** Anti-IL6R-Alexa594 NP were found in the lung parenchyma and in the hilar lymph nodes. Immunofluorescence staining assay demonstrated that CD163$^+$, CD11b$^+$, HLADR$^+$, and CD11c$^+$ cells from hilar lymph node internalized NPs. The

same held true for the lung parenchyma tissue with the addition of $CD3^+$ cells also having nanoparticle uptake. Approximately 10% of the lymph node macrophages ($HLADR^+$, $CD11b^+$, $CD163^+$) and 50% of the pulmonary macrophages had NP uptake. Figure 1: Immunofluorescence imaging of lung parenchyma. Blue = DAPI, Green = $HLADR^+$, Red = NP.

Conclusions: In this study, we synthesized bright nanovesicles to track the fate of NPs in the lung. These biocompatible NP produced sustained release of their loaded anti-IL6R over the span of two weeks in physiological condition, offering a way to control immune reactions locally. Despite the short perfusion time, a significant number of lung alveolar macrophages were able to phagocytose NPs. This is a promising new avenue for drug delivery in hopes of reducing incidence and severity of lung PGD.

Abstract# 308

Targeting Calcineurin/nfatc2 Signaling to Restore Pancreatic Beta-cell Function in Islet Transplantation

C. Darden[1], J. Mattke[1], S. Vasu[1], K. Kumano[1], Y. Liu[1], B. Naziruddin[2], M. C. Lawrence[1], *[1]Baylor University Medical Ctr, Dallas, TX, [2]Baylor University Medical Ctr, Allen, TX*

Purpose: Pancreatic beta cells dedifferentiate upon exposure to metabolic and inflammatory stress characterized by loss of beta-cell identity genes, expression of beta-cell disallowed genes, and loss of function. Here we sought to elucidate cell signaling pathways regulating genes during adaptive stress responses to identify cellular targets for restoring and maintaining islet cell function during islet isolation procedures and transplantation.

Methods: Human and mouse islets were isolated form donor pancreases and treated with high glucose (16.7 mM) and cytokine cocktail (IL-1β, TNF-α, and IFN-γ) for 2h and 24h. Transgenic mice harboring $INS1^{CRE/ERT2}$:$NFATc2^{f/f}$ were used for beta-cell knock out (BKO) islets. Gene expression was analyzed by RNA-Seq and QPCR. Western blot analyses used anti-RFX6 and MCT-1 antibodies. Promoter analyses were performed by promoter-reporter and ChIP assay. Ca^{2+} fluorometric imaging quantified intracellular Ca^{2+} changes. ELISA measured glucose-stimulated insulin secretion functional assays on islets.

Results: Both human and mouse islets exposed to acute (2h) metabolic and inflammatory stress showed enhanced upregulation of several beta-cell differentiation genes. In contrast, long-term exposure of islets (>24h) to stress resulted in downregulation of beta-cell differentiation genes and induction of more than twenty disallowed beta-cell genes. Transcriptional changes of several of these key genes including RFX6 and MCT-1 during extended stress exposure were due to downstream ER stress, Ca^{2+} impairment, and loss of CN/NFATc2 signaling. Ca^{2+} and CN/NFATc2 signaling were restored in beta cells by small molecule ISX9, a differentiation inducer. Transgenic BKO islets showed spontaneous beta-cell dedifferentiation, dysregulated insulin secretion, and could not be restored by ISX9.

Conclusions: CN/NFATc2 regulate genes that maintain beta cells in a differentiated state during islet cell stress and are lost upon sustained ER stress and overstimulated intracellular Ca^{2+}. Reactivating Ca^{2+}/CN/NFAT signaling with ISX9 induces redifferentiation of stressed islets and restores them to a functional state. The study suggests that CN/NFATc2 can be targeted to restore and maintain potency of islets during inflammatory stresses imposed throughout procedures of islet transplantation.

Abstract# 309

A Fresh Look at Urbanicity and Its Impact on Additions to the Kidney and Liver Transplant Wait Lists

W. R. Johnson, S. A. Rega, I. D. Feurer, S. J. Karp, *General Surgery, Vanderbilt University Medical Center, Nashville, TN*

Purpose: Our aim is to examine the collective effects of social determinants of health (SDH) on kidney and liver wait list additions in the United States.

Methods: Principal components analysis of 127 county-level socioeconomic (SE) and health-related (HR) variables from publicly available American Community Survey, Robert Wood Johnson County Health Rankings, and Institute for Health Metrics and Evaluation datasets was used to identify two SDH composites. Population-weighted composite scores were computed for 50 states and the District of Columbia (analysis N=51). 53,004 adult kidney and 21,701 adult liver waitlist additions in 2017-2018 and listing center density (population-adjusted number of centers per state) were determined using Scientific Registry of Transplant Recipients data. End-stage renal disease incidence and potentially transplantable liver mortality were determined using United States Renal Data System and National Center for Health Statistics data. Multiple linear regression models evaluated the effects of composite scores, listing center density, and whether Medicaid expansion was accepted on disease- and population-adjusted numbers of kidney and liver transplant wait list additions.

Results: Two SDH composites were identified: 1) SE/HR and 2) urbanicity. After adjusting for listing center density and Medicaid expansion (all $p>0.12$), state-level kidney and liver transplant disease- and population-adjusted wait list additions were significantly associated with urbanicity (both $p<0.05$) and not with the SE/HR composite [Table 1].

Conclusions: Listing for kidney and liver transplant in the United States is independently associated with urbanicity; the collective impact of SE/HR was not independently associated with wait list additions in this study. Policy and quality improvement initiatives should be directed towards bridging the gap in wait list access between urban and rural populations. Furthermore, consideration should be given to investigating the collective effects of SDH on all transplant milestones.

Table 1: Multiple Linear Regression Models of Disease Burden-Adjusted Wait List Additions. (N=51 States and the District of Columbia)

Organ	Kidney ($R^2 = 0.15$)		Liver ($R^2 = 0.12$)	
Variables	Standardized Coefficient	*p*-Value	Standardized Coefficient	*p*-Value
SE/HR* Composite Score	-0.01	0.93	0.05	0.75
Urbanicity Composite Score	0.40	**0.01**	0.36	**0.04**
Listing Center Density	-0.23	0.13	-0.02	0.90
Medicaid Expansion	-0.07	0.62	-0.04	0.80

Abstract# 310

Racial and Sexual Disparities in Solid Organ Transplant Outcomes Since Implementation of the Affordable Care Act Insurance Expansion Across Some States

H. Mohamed[1], C. Conceicao[2], A. Kumar[1], J. Buggs[3], *[1]Morsani College of Medicine, University of South Florida, Tampa, FL, [2]Honors College, University of South Florida, Tampa, FL, [3]Transplant Surgery, Tampa General Hospital, Tampa, FL*

Purpose: Achieving solid organ transplantation traditionally requires access to health insurance. As such, women and people of color have faced barriers to obtaining solid-organ transplants. The Affordable Care Act (ACA) expanded Medicaid eligibility and thus has decreased health disparities among women and minorities. The goal of this project was to determine any differences in transplant outcomes by sex and race in states that have implemented the ACA expansion of healthcare insurance. We hypothesized that there will be an improvement by sex and race in transplant outcomes in states that have implemented the ACA expansion of healthcare insurance.

Methods: We conducted a retrospective cohort study of all consecutive patients in the U.S. undergoing heart, kidney, lung, and liver transplants from Jan. 2010 to Dec. 2019. Patient data was obtained from the United Network for Organ Sharing and the Organ Procurement and Transplantation Network. Pediatric patients and multiorgan recipients were excluded. Variables, including demographics, were examined. There were four racial categories recorded (White, Black, Hispanic, and Other). We looked at the number of transplants before and after the ACA expansion for each organ system and reviewed the results based on sex and race.

Results: There was an increase in the number of transplants for both males and females post-ACA expansion across all organ systems. However, male patients showed a significantly higher increase as compared to female patients with regards to liver transplants (p=0.010). There was an increase in the number of transplants for all races/ethnicities post-ACA expansion across all organ systems (Figure 1). However, the rate of increase was not equal. White patients saw a higher increase in the number of transplants as compared to non-white patients across all organ systems (p<0.001).

Conclusions: Since the implementation of the ACA, which granted greater access to insurance, sexual and racial disparities have decreased. However, these disparities still exist with solid organ transplantation. Explanations associated with these inequalities are multifaceted and need to be further explored to facilitate the development of solutions that advance the system while improving transplant patient outcomes by race and sex.

Abstract# 311

The Impact of the Covid-19 Pandemic on Measures of Transplant Activity is Higher in Lower-Income Countries: A Multinational Survey Study

S. Sandal[1], B. Boyarsky[2], P. Chiang[2], A. Massie[2], D. Segev[2], M. Cantarovich[1], *[1]McGill University, Montreal, QC, Canada, [2]Johns Hopkins University, Baltimore, MD*

Purpose: The COVID-19 pandemic has affected the field of solid organ transplantation due to the "ramp-down" of activity during the initial months. Impact on transplant activity may vary by baseline health system vulnerabilities. We aimed to analyze this by a country's cumulative COVID-19 incidence (CCI) and income-level.

Methods: From June-September 2020, we conducted a multinational survey of transplant physicians. Of 1,267 physicians contacted, 40.5% from 71 countries participated. Income-level was assigned as per the World Bank Classification. CCI was calculated in person per million population (ppm) from March-July and divide into tertiles for the entire cohort (low: <2031ppm, medium: 2032-5400ppm, high: >5400ppm). Logistic regression was used to conduct a comparative analysis.

Results: Overall, 75.2% of the programs reported a ramp-down phase, 76.8% performed transplants during this time, 69.6% reported fewer deceased donor offers, and 59.6% anticipate transplant volumes will be <75% of the norm in 2020. Compared with low/lower-middle income countries, transplant programs from high-income countries had 69% lower odds of a ramp-down phase and 50% lower odds of reporting fewer deceased donor offers. Also high income countries had higher odds of performing at least one transplant (OR=3.19, 95%CI: 1.55-6.60, p=0.002) and maintaining transplant volumes >75% (OR= 2.34, 95%CI: 1.20-4.58, p=0.01). CCI was not associated with any of these outcomes except fewer deceased donor offers in programs with moderate CCI. As shown in Table 1, kidney/pancreas transplant programs may be disproportionately affected during the pandemic.

Conclusions: We report transplantation has incurred substantial collateral damage from the COVID-19 pandemic and measures of transplant activity during the initial months were significantly associated with the income-level of the country independent of the COVID-19 burden. It will take global effort from transplant leadership to rebuild disrupted transplant services, in particular in, countries that already have vulnerable health systems.

Table 1:The odds ratio for four outcomes of interest	Odds of reporting a ramp-down phase	Odds of performing a transplant/s	Odds of receiving fewer/much fewer deceased donor offers	Odds of maintaining a transplant volume >75% in 2020

Abstract# 312

Black Patients with Cirrhosis Have Longer Length of Stay and Higher Mortality When Hospitalized

A. Thomas[1], D. Simpson[2], D. P. Ladner[2], R. Berkowitz[2], *[1]ACS Clinical Scholar, Chicago, IL, [2]Transplant Surgery, Northwestern University Feinberg School of Medicine, Chicago, IL*

Purpose: Black patients with cirrhosis have been shown to have higher liver-related mortality compared to White patients. However, little knowledge exists about racial differences related to length of stay and in-hospital mortality at 60 days in patients who are hospitalized for cirrhosis. To this end, we aim to characterize the LOS among hospitalized patients with compensated vs. decompensated cirrhosis stratified by race in the United States.

Methods: A retrospective review of adult (>18 yrs) patients with cirrhosis was performed using the Nationwide Inpatient Sample data from 2010-2014. Validated ICD/CPT algorithms were used to identify cirrhosis and related complications (HE,

SBP, ascites, GIB, HRS, HPS). Descriptive analysis and cox regression analysis were performed and dichotomized by race (White vs Black) for outcomes (LOS, In-hospital mortality).

Results: Between 2010-2014, 879,216 hospitalizations were observed in patients with cirrhosis for a total of 5,674,320 total hospitalization days. The mean age was 62±14.8, 42.3% (N=371691) were female, 68.5% were White, 11.7% Black, 13.9% Hispanic, and 5.9% Other. 51.7% were insured with Medicare, 18.1% Medicaid, 19.7% private, 6.1% self-pay (Table 1). Clinically significant differences between Blacks and Whites were observed for HCV (31% vs 19%), Medicaid (15% vs 21%) and Private (15% vs 21%). 434,712 patients (52.8%) had decompensated cirrhosis (31.7% HE, 2.7% SBP, 24.7% ascites, 4.5% GIB, 3.5% HRS) and 3.6% had HCC. Patients with cirrhosis had a mean of 7.0 (3.1) chronic conditions. In-hospital mortality in Whites was 5.9% compared to 6.7% in Blacks (p<0.001). The median LOS was 4 (2-7) days for Whites and 5 (3-9) days for Blacks (p<0.001). Survival in Whites was 8% increased to Blacks (HR 1.08, 1.05-1.18) (Figure 1).

Conclusions: In a national in-patient cohort sample, Black patients with cirrhosis have longer hospitalizations at baseline. Black patients in decompensated cirrhosis have lower survival than White patients.

Characteristics	Black (N=96,286)	White (N=565,844)	P-value
Age (mean)	59.7 (14)	63.2 (14)	< 0.01
Female	244,926(43.3%)	41,112 (42.7%)	<0.01

Abstract# 313

Prediction of Renal Allograft Tolerance by Machine Learning

Q. Fu[1], K. Deng[2], H. Yang[1], S. Deng[1], J. F. Markmann[2], *[1]Organ Transplantation Center, Sichuan Provincial People's Hospital, University of Electronic Sciences and Technology of China, Chengdu, China, [2]Center for Transplantation Sciences, MGH, Boston, MA*

Purpose: An ideal goal of transplantation is to withdraw or minimize immunosuppressants via the induction of tolerance to overcome drug toxicity, prolong allograft survival, and improve the quality of patient life. Many efforts have been taken to find the potential biomarkers for tolerance using the limited number of patients due to complicated mechanisms underlying tolerance and the potential risk of rejection after immunosuppressant withdrawal. Through comparing high-dimensional genome-wide expression data with machine learning algorithms potential biomarkers for allograft tolerance can be found.

Methods: Several databases were combined based on the same platform (GPL570), performed, and compared 14 different machine learning models for tolerance prediction using peripheral blood mononuclear cells (PBMCs).

Results: The Ridge regression was the most powerful method with a specificity of 90.0% and a sensitivity of 92.3%. Additionally, we identified an 8-gene feature (TCL1A, IGHG1, VPREB3, Septin9, TUBB2A, CCR2, RBM14, and WASL) using the Lasso model, 3 of which were B-cell-related, obtaining a similarly accurate performance with a specificity of 86.7% and a sensitivity of 92.3%. This 8-gene signature accurately differentiated tolerant patients from stable patients in a second validation group.

Conclusions: The Lasso regression model may provide an indication for clinicians to determine the right time for immunosuppressant withdrawal with a low risk of rejection or immunosuppressant side-effects.

Abstract# 314

The Role of Pre-transplant Rectal Screening for Azole-resistant Candida Species in Liver Transplant Candidates

K. K. Patel[1], M. M. Azar[2], A. Koff[3], K. Belfield[4], D. R. Peaper[5], J. Topal[2], M. Malinis[2], *[1]Yale School of Medicine, New Haven, CT, [2]Section of Infectious Diseases, Yale School of Medicine, New Haven, CT, [3]Section of Infectious Diseases, UC Davis, Sacramento, CA, [4]Department of Pharmacy, Yale New Haven Hospital, New Haven, CT, [5]Department of Laboratory Medicine, Yale School of Medicine, New Haven, CT*

Purpose: Azole-resistant *Candida* (ARC) infections have become increasingly common among solid organ transplant recipients. Pre-transplant screening for ARC allows for targeted antifungal prophylaxis, which may reduce the incidence of post-transplant ARC infection. In this study, we describe a single-center experience of routine ARC screening in liver transplant (LT) candidates.

Methods: We performed a retrospective chart review of patients who underwent LT at Yale-New Haven Hospital from April 2019 to November 2020. ARC (*C. glabrata* and *C. krusei*) screening was performed via a rectal swab prior to or at

time of LT. Collected data included patient demographics, ARC screening, antifungal prophylaxis, risk factors associated with *Candida* infection (previously defined by AST ID COP guidelines), and *Candida* infection within 1 month of LT.
Results: Forty patients underwent LT. The median age was 59 years (range 25-70), 27 (68%) were male, and 19 (48%) had a MELD ≥ 30 at time of LT. Of this cohort, 34 (85%) had ARC screening. ARC colonization was present in 7/34 (21%) patients: *C. glabrata* (n=4), *C. krusei* (n=2), and both species (n=1). All 7 patients received antifungal prophylaxis. Echinocandin prophylaxis was given in 4/7 (57%), of whom 1 developed confirmed ARC infection (*C. krusei* and *C. glabrata* fungemia). Three ARC colonized patients received fluconazole but none developed post-LT *Candida* infection. In non-ARC colonized patients on fluconazole prophylaxis, 1 developed *C.krusei* peri-hepatic abscess and 1 had suspected *Candida* subhepatic abscess due to elevated serum β-d-Glucan. The 6 patients without ARC screen did not develop post-LT *Candida* infection.The median time to post-LT *Candida* infection was 25 days (range 24-26). The median number of risk factors among 3 patients with post-LT *Candida* infection was 2 vs. 1 among 31 patients without post-LT *Candida* infection.
Conclusions: Screening for ARC may assist in selecting appropriate antifungal prophylaxis for LT patients but it may not be sufficient to prevent infection in those with multiple risk factors for post-transplant *Candida* infection. Larger studies are required to evaluate further the role of ARC screening in antifungal stewardship in LT.

Abstract# 315

A Machine Learning-Based Predictive Model for Outcome of Covid-19 in Kidney Transplant Recipients

I. Revuelta[1], F. Santos-Arteaga[2], D. Di Caprio[3], E. Montagud-Marrahi[1], F. Cofan[1], J. Torregrosa[1], M. Bodro[4], A. Moreno[4], P. Ventura-Aguiar[1], D. Cucchiari[1], N. Esforzado[1], G. Piñeiro[1], J. Ugalde-Altamirano[1], J. Campistol[1], A. Alcaraz[5], B. Bayès[1], E. Poch[1], F. Oppenheimer[1], F. Diekmann[1], *[1]Department of Nephrology and Kidney Transplant, Hospital Clinic, Barcelona, Spain, [2]Faculty of Economics and Management, Free University of Bolzano, Bolzano, Italy, [3]Department of Economics and Management, University of Trento, Trento, Italy, [4]Department of Infectious Diseases, Hospital Clinic, Barcelona, Spain, [5]Department of Urology, Hospital Clinic, Barcelona, Spain*
Purpose: Health systems need tools to deal with COVID-19, especially for high-risk population,such as transplant recipients. Predictive models are necessary to improve management of patients and optimize resources.
Methods: A retrospective study of hospitalized transplant patients due to COVID-19 was evaluated(March 3-April 24,2020). Admission data were integrated to develop a prediction model to evaluate a composite-event defined as Intensive Care Unit admission or intensification treatment with antiinflamatory agents. Predictions were made using a Data Envelopment Analysis(DEA)-Artificial Neural Network(ANN) hybrid, whose accuracy relative to several alternative configurations has been validated through a battery of clustering techniques.
Results: Of 1006 recipients with a planned or an unscheduled visit during the observation period, thirty-eight were admitted due to COVID-19. Twenty-five patients(63.2%) exhibited poor clinical course(mortality rate:13.2%), within a mean of 12 days of admission stay. Cough as a presenting symptom(P=0.000), pneumonia(P=0.011), and levels of LDH(P=0.031) were admission factors associated with poor outcomes. The prediction hybrid model working with a set of 17 input variables displays an accuracy of 96.3%, outperforming any competing model, such as logistic regression(65.5%) and Random forest(denoted by Bagged Trees,44.8%). Moreover, the prediction model allows us to categorize the evolution of patients through the values at hospital admission.
Conclusions: The prediction model based in Data Envelopment Analysis-Artificial Neural Network hybrid forecasts the progression towards severe COVID-19 disease with an accuracy of 96.3%, and may help to guide COVID-19 management by identification of key predictors that permit a sustainable distribution of resources in a patient-centered model. Improving efficiency and patient performance in the AAN with DEA, we can get high accurancy even with no-big cohorts.

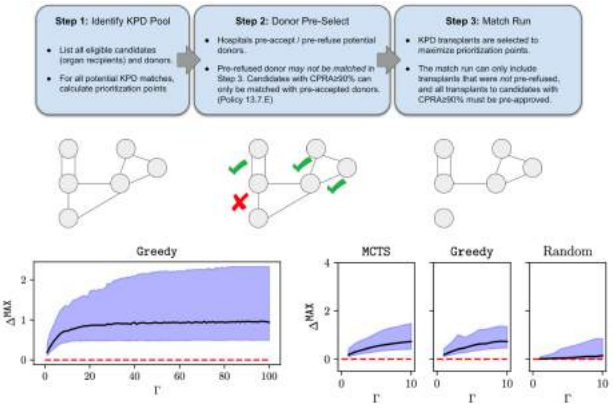
Abstract# 316

Improving Policy-constrained Kidney Exchange via Pre-screening

D. C. McElfresh[1], M. Curry[2], S. Booker[3], M. Stuart[3], D. Stewart[3], R. Leishman[3], T. Sandholm[4], J. Dickerson[2], *[1]Applied Mathematics, University of Maryland, College Park, MD, [2]University of Maryland, College Park, MD, [3]United Network for Organ Sharing, Richmond, VA, [4]Carnegie Mellon University, Pittsburgh, PA*
Purpose: Many planned kidney exchange transplants do not go to transplantation (they "fail") for a variety of reasons, such as positive crossmatch and logistical difficulties. Failures reduce the number of transplants facilitated by exchanges, and increase patient waiting time. Avoiding failures is a challenge, as exchanges are often constrained by policy and law in how they match patients and donors.



Instead, hospitals can pre-screen potential donors prior to matching. Donors who are not rejected during pre-screening can then be matched in the exchange (Fig. 1-Top). Pre-screening requires clinicians to spend valuable time reviewing potential donors, as well as additional compatibility testing. Since each hospital can have dozens of potential donors to screen, it is important to prioritize those most important to the exchange.

Methods: We study how to select donors for pre-screening, using a theoretical model and computational simulations. In our model each transplant has a probability of being approved/rejected during screening, and a probability of post-match failure. Using this model we estimate the value gained by pre-screening each donor (the total increase OPTN prioritization points). Values help determine which transplants are most important to pre-screen.

Results: Selecting the most valuable donors to pre-screen is computationally hard (see our paper for details), but simple algorithms are effective in simulations. Fig. 1-Bottom shows simulation results on OPTN-KPD exchanges from 2010-2018, using our methods Greedy and MCTS, compared to a Random baseline. Horizontal axis: number of donors pre-screened; vertical axis: relative value improvement over no pre-screening,: 0 = no improvement, 1 = 100% more prioritization points, and so on. Shading shows the range over all exchanges, and solid line shows the median. in most cases, screening only 10 donors with our methods leads to a 50-100% increase in matched prioritization points. Selecting random donors yields a much smaller improvement.

Conclusions: Pre-screenings can prevent pre-transplant failures, but cost valuable time and resources. We develop algorithms for identifying which donors provide the most value to the exchange if pre-screened. Our methods can help hospitals prioritize the most important donors to screen, and to filter out donors which cannot be matched via exchange. We are now working with the OPTN KPD program to implement these methods in a pilot test.

Kidney

Kidney Antibody Mediated Rejection

Abstract# 317

DSA Causes Mild Molecular ABMR-like Changes in Many Biopsies Not Diagnosed as Rejection

P. F. Halloran[1], K. S. Madill-Thomsen[1], &. the INTERCOMEX Study Group[2], *[1]Alberta Transplant Applied Genomics Centre, Edmonton, AB, Canada, [2]., ., AB, Canada*

Purpose: In the multicenter study INTERCOMEX, we developed a microarray-based system (MMDx) for diagnosing antibody-mediated and T cell-mediated rejection (ABMR, TCMR) in kidney transplant biopsies using an ensemble of machine-learning classifiers. Here we use an expanded set of 1679 biopsies to explore the significance of DSA positivity in kidneys without rejection.

Methods: Machine learning was used as previously described, based on gene expression (*Am J Transplant.* 2019;19:2719). A new DSA classifier (DSAprob) was trained on DSA+ vs DSA- samples, with probabilities assigned in the left-out folds of 10-fold cross-validation. We plotted the biopsy samples' molecular distribution using Uniform Manifold Approximation and Projection (UMAP), a recently developed dimensionality reduction method. The inputs were seven molecular rejection scores, built for predicting TCMR, ABMR, and i-, t-, ptc-, g-, and cg-lesions.

Results: Figure 1A is a UMAP plot colored by MMDx diagnoses, mapping ABMR, TCMR, possible rejection (pABMR, pTCMR), Mixed, and No rejection. Figure 1B is the same distribution colored by DSAprob classifier scores, showing that a gradient of mild ABMR-related changes exists within No Rejection biopsies. There was also a gradient within ABMR correlating with stage (early>late) and in TCMR associated with Mixed rejection.

Within ABMR, DSAprob was higher in DSA+ than DSA- biopsies, but mild DSA-related changes were also detected in biopsies with No Rejection (NR), either by MMDx or histology (Table 1). DSAprob predicted DSA status, indicating the molecular changes detected in NR biopsies were DSA-related. In 738 biopsies with no rejection by MMDx, the 369 with high DSAprob scores (above the median) were more often DSA positive (36%) than those with low DSAprob scores (24%) (chisq pval=0.0004). Thus ABMR-related gene expression changes in No rejection biopsies are associated with DSA positivity.

NR biopsies with high DSAprob scores also had increased scores for other ABMR and NK-related classifiers and gene sets, but not TCMR or injury-related classifiers and gene sets.

Conclusions: A gradient of mild ABMR-related gene expression including NK-related and IFNG-related changes exists in many kidneys currently called no rejection that corresponds to a higher frequency of DSA, indicating that mild molecular ABMR-related changes occur in many more kidneys than currently diagnosed as ABMR by MMDx or by histology. DSA is likely stressing the microcirculation more widely than previously realized. (ClinicalTrials.gov NCT01299168 (kidney).

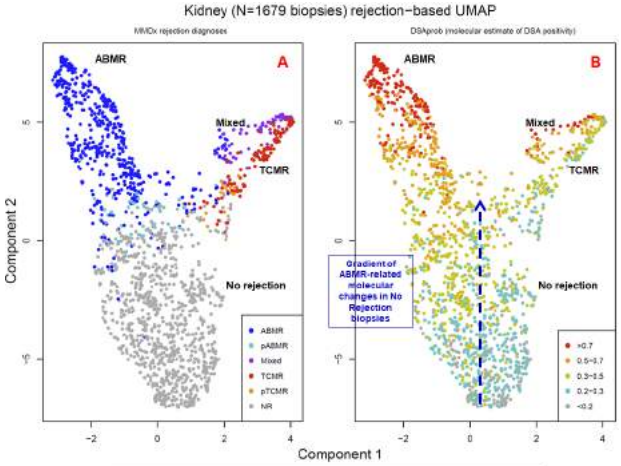

Table 1. Mean DSA probabilities in DSA positive vs negative biopsies across MMDx and histologic categories (Welch's t-test p values)

Abstract# 318

Beyond Microarrays: Insights from Ncounter Transcript Analysis of Routine Archival Kidney Allograft Biopsies

I. Rosales, K. Tomaszewski, A. Milagros, T. Kawai, R. Smith, R. Colvin, *Massachusetts General Hospital, Boston, MA*

Purpose: Microarray mRNA analysis of renal allograft biopsies has discovered important insights, but has limitations as a practical clinical test. Here we evaluate a new technique that quantifies transcripts from routine formalin fixed paraffin embedded (FFPE) tissue.

Methods: Gene expression was measured from 140 renal allograft biopsy samples (2003-2020): 45 chronic, active antibody mediated rejection (CAMR), 38 T cell mediated rejection (TCMR), 26 without evidence of rejection (NER), 19 borderline/suspicious (BS), 4 C4d+ NER, 8 living donor and 8 control native biopsies. RNA was extracted from 3 FFPE 20 µm sections and hybridized with the Banff Human Organ Transplant (B-HOT) 758 gene panel (NanoString) and quantitated (nCounter Max). Data were analyzed using the NanoString software with custom pathways and results correlated with Banff scores from the same biopsy core and outcome at 3 years.

Results: Many gene sets discriminated CAMR from TCMR. The best were DSAST (Hidalgo 2011, $p=1.28x10^{-9}$ Fig 1A, AUC 87.5%) and TCMR (Venner 2014; $p=1.3x10^{-8}$;AUC 84.9%), both derived from microarray studies, and CAMR NHP (Smith 2018; $p=10^{-6}$). TCMR pathway scores were reduced in responsive post-treatment biopsies. C4d+ CAMR had higher levels of AMR, B and T cell pathways than C4d- CAMR. Selective glomerular injury could be detected in CAMR. Biopsies with higher microvascular inflammation (g+ptc, Fig 1B) and transplant glomerulopathy (cg, Figure 1C) had a progressive reduction of glomerular endothelial transcripts (*EHD3, SOST*) and podocyte specific transcripts (*NPHS1, NPHS2*), but these were not affected by C4d deposition. In contrast, pan-endothelial transcripts (e.g., *CAV1, CDH5, PECAM1*) were increased (Fig 1D). Graft loss at 3 years after

TCMR/BS was rare, but those that failed showed higher endothelial scores due to occult AMR. Graft loss at 3 years in CAMR was associated with higher damage pathway scores but was not associated with increased AMR pathways.
Conclusions: Robust transcript data can be obtained from routine archival FFPE clinical biopsies using NanoString technology and the B-HOT panel. Several pathway scores distinguish CAMR and TCMR with reasonable ROC performance. New findings suggest microvascular inflammation, independent of complement activation, causes glomerular injury in CAMR. Damage pathway scores rather than AMR or TCMR pathways predicted CAMR outcomes, but AMR pathways were predictive of rare graft failure in TCMR/BS biopsies.

Abstract# 319

Transplant Glomerulopathy in the Absence of Donor-specific HLA Antibodies: Risk Factors, Histopathological Features and Graft Outcome

A. Senev, E. Van Loon, M. Emonds, M. Naesens, *Microbiology, Immunology and Transplantation, KU Leuven, Leuven, Belgium*

Purpose: Transplant glomerulopathy (TG) is established as a hallmark of chronic antibody-mediated rejection in kidney transplant patients with donor-specific HLA antibodies (HLA-DSA). The clinical importance of TG in the absence of HLA-DSA is not well established.
Methods: Patients who underwent kidney transplantation between 2004-2013 were included in this study (N=954 with 3744 biopsies). We investigated the risk factors, histopathological appearance and prognosis of cases with TG in the absence of HLA-DSA, compared to cases of TG with HLA-DSA, and we evaluated the impact of the PIRCHE-II score and eplet mismatches, determined using high-resolution HLA genotyping, on TG development.
Results: In this cohort, 98 patients (10.3%) developed TG, on average at 3.2 years posttransplant. At the time of TG, 23 patients (23.5%) had persistent pretransplant or *de novo* HLA-DSA (HLA-DSA_{pos}TG group), while 75 patients (76.5%) were HLA-DSA negative (HLA-DSA_{neg}TG). Only HLA-DSA were identified as risk factor for TG development; HLA molecular mismatches, eplet mismatches and PIRCHE-II scores did not associate with TG. The HLA-DSA_{neg}TG biopsies had less interstitial inflammation, less glomerulitis and less C4d deposition in peritubular capillaries compared to the HLA-DSA_{pos}TG biopsies. While graft function was comparable between the two groups, HLA-DSA_{pos}TG was associated with a higher risk of graft failure compared to HLA-DSA_{neg}TG (HR=3.84; 95%CI 1.94-7.59; p=0.0001). Landmark analysis at 3-year post-transplant showed that HLA-DSA_{neg}TG patients still had an increased risk of graft failure compared to TG-negative patients (HR=2.62; 95%CI 1.46-4.72; p=0.001).
Conclusions: In conclusion, TG often occurs in the absence of HLA-DSA, independently of HLA molecular mismatches, and represents a different phenotype with less concomitant inflammation and better graft survival compared to TG developed in the presence of HLA-DSA.

Figure 1. Landmark survival analysis of the patients with TG.

Abstract# 320

High Donor-Derived Cell-Free DNA Levels Predict Development of De Novo HLA Donor-Specific Antibodies After Kidney Transplantation - Data from the ADMIRAL Study

G. Gupta[1], T. Alhamad[2], V. Bowers[3], I. Moinuddin[1], S. Ghosh[4], J. Zeng[4], E. Stites[5], A. Pai[6], J. S. Bromberg[7], S. Anand[8], *[1]Virginia Commonwealth University, Richmond, VA, [2]Washington University in St. Louis, St. Louis, MO, [3]Tampa General Hospital, Tampa, FL, [4]CareDx, Brisbane, CA, [5]University of Colorado, Aurora, CO, [6]University of Texas McGovern Medical School, Houston, TX, [7]University of Maryland School of Medicine, Baltimore, MD, [8]Intermountain Medical Center, Murray, UT*

Purpose: Donor-derived cell-free DNA (dd-cfDNA) as a marker of injury can serve to quantify *subclinical* inflammation and molecular injury. As the release of graft genomic material is ongoing into recipient's circulation, such processes may contribute to recipient immune sensitization. Donor-derived nucleic acids, as reflected in elevated dd-cfDNA levels, may result in leucocyte activation, cytokine release, and *de novo* donor specific antibody (dnDSA) formation. We hypothesized elevated dd-cfDNA levels may predict subsequent HLA dnDSA development after kidney transplant (KT).
Methods: 961 patients from the prospective multicenter Assessing dd-cfDNA monitoring insights of renal allograft with longitudinal surveillance (ADMIRAL study; clinicaltrials.gov: NCT04566055219) were examined. All patients had dd-cfDNA (AlloSure®; CareDx) levels monitored during standard post-KT surveillance and paired HLA DSA testing, with all clinical events captured. An elevated dd-cfDNA was defined as >0.5% based on the injury analysis performed within ADMIRAL cohort.
Results: Multivariable Cox proportional hazards regression analysis [**FIGURE 1**] supported an effect size of 1.2 (p =0.004), for dd-cfDNA, indicating 20% increased risk of dnDSA for every 1% increase in the dd-cfDNA level. The majority of dnDSA were diagnosed within the 1st year post-KT. The median elevation of dd-cfDNA was 291 days preceding detection of dnDSA, suggesting elevations of dd-cfDNA may happen ahead of DSA formation. By dichotomizing the continuous dd-cfDNA predictor at a threshold 0.5% (low: <0.5%) - case-control numbers shown in **TABLE 1** - a significantly increased hazard ratio (HR) of 2.57 (p=0.003) for development of dnDSA was observed. [**FIGURE 2**].

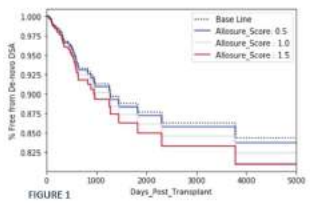

FIGURE 1

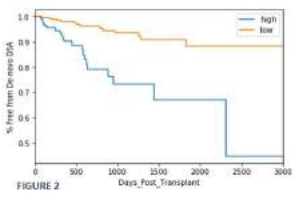

FIGURE 2

# of Cases	0-500 (days post-KT)	500-1000	1000-1500	1500-2000	2000-2500	2500-3000	>3000
Low (≤0.5)	808	207	103	49	27	16	10
High (>0.5)	153	57	23	11	8	2	1

TABLE 1

Conclusions: Higher dd-cfDNA levels appear to precede the development of dnDSA after KT. A potential causal relationship of dd-cfDNA and dnDSA will require further

study. A prospective interventional study, implementing dd-cfDNA monitoring and real-time targeted immunomodulation in response to dd-cfDNA levels, may provide significant value to patient care.

Abstract# 321

Novel Mixed Lymphocyte Reaction Monitoring System That Predicts Chronic Antibody- Mediated Rejection in Kidney Transplant Recipients

N. Iwahara[1], K. Hotta[1], T. Tanabe[1], D. Iwami[2], Y. Takada[3], H. Higuchi[1], H. Sasaki[3], H. Harada[3], N. Shinohara[1], *[1]Hokkaido Univercity, Sapporo, Japan, [2]Jichi Medical University, Shimotsuke, Japan, [3]Sapporo City General Hospital, Sapporo, Japan*

Purpose: Chronic active antibody-mediated rejection (CAAMR) induced by *de novo* donor-specific antibodies (DSA) is the main cause of graft loss in the long-term. Currently, there is no effective treatment or predictive marker for CAAMR exists. Therefore, a reliable immunoresponse monitoring system to identify recipients who will develop CAAMR in the future is required to improve long-term allograft survival. A novel CFSE/MLR assay was developed to evaluate T cell responses in kidney transplant recipients.

Methods: This assay was developed using isolated T cells as responders, which is much more sensitive to detect T cell responses compared with the standard MLR using PBMCs. In this study, 84 kidney transplant recipients were evaluated using this novel assay. The recipients were divided into two groups (stable; n=60, DSA+; n=24) and their T cell responses were compared.

Results: In pathological analyses, all recipients in the stable group experienced any incidents of rejection, whereas 18 DSA+ recipients developed CAAMR and 6 DSA+ recipients still did not develop CAAMR (pre-CAAMR). The MLR assay revealed that the anti-donor $CD4^+$/$CD8^+$ T cell responses were significantly higher in DSA+ recipients than in stable recipients. Interestingly, in stable recipients, the anti-donor $CD4^+$ T cell response was significantly lower than the anti-third-party response, and the donor-specific hyporesponsiveness was also observed in $CD8^+$ T cells. In contrast, donor specific hyporesponsiveness of $CD4^+$ T cells disappeared in DSA+ recipients. To elucidate the underlying mechanisms for DSA production, the levels of INF-γ, IL-4, IL-17 and FOXP3 in responder T cells were evaluated to identify which $CD4^+$ T cell subsets were expanding. Proliferating $CD4^+$ T cells showed a marked increase in the Th1 ($CD4^+INF\text{-}\gamma^+$) and Th17 ($CD4^+IL\text{-}17^+$) response in DSA+ recipients, whereas there was no difference in donor reactive Th2 ($CD4^+IL4^+$) and Treg ($CD4^+FOXP3^+$). Evaluation of the six pre-CAAMR recipients showed a similar $CD4^+$ T cell landscape, suggesting that the novel MLR assay can predict the development of CAAMR.

Conclusions: DSA+ recipients have a greater potential for immune responses against the donor tissue. CFSE/MLR using isolated T cells is a useful immunoresponse monitoring system to predict the development of CAAMR.

Figure: CFSE/MLR in 84 kidney taransplant recipients

The Trifecta Study: Calibrating Circulating Donor-Derived Cell-Free DNA at the Time of Indication Biopsies Against the Molecular Phenotype of the Biopsy Reveals a Prominent Association with NK Cell Genes

P. Halloran[1], Z. Demko[2], A. Prewett[2], J. Reeve[1], P. Billings[2], *[1]Alberta Transplant Applied Genomics Centre, Edmonton, AB, Canada, [2]Natera Inc., San Carlos, CA*

Purpose: The international, multicenter, prospective Trifecta study was designed to calibrate dd-cfDNA% measurements in blood at the time of indication biopsy against the molecular characteristics of the biopsies using the Molecular Microscope® (MMDx) (*ClinicalTrials.gov NCT04239703).*

Methods: MMDx was used to assess TCMR, ABMR, acute kidney injury, atrophy-fibrosis, and genome-wide gene expression in the biopsy samples. dd-cfDNA% assays (Prospera) were performed on blood samples by Natera. We analyzed 189 biopsies from 14 centers. By MMDx, the diagnoses were: No rejection 104; ABMR 43; Possible ABMR 16; Mixed 7; TCMR 14 (5 with histologic BK); Possible TCMR 5.

Results: The 20 genes most strongly correlated with dd-cfDNA% are shown in **Table 1**. Most (20/21) were genes annotated as ABMR-rejection associated (ABMR-RATs) from previous studies. Most were expressed in NK cells (GNLY TRDC, CCL4) or represented IFNG effects (PLA1A, LYPD5 (LY6), IDO1, CXCL11). Endothelium-expressed genes were not prominent. By MMDx diagnosis, dd-cfDNA% was strongly related to active early stage- and fully-developed ABMR. In principal component analysis (**Figure 1**) using rejection classifiers as inputs, dd-cfDNA% correlated with ABMR in PC1 and PC2, and with early stage and fully developed ABMR in PC3. The results were less consistent in TCMR, and some biopsies with no MMDx rejection had high %dd-cfDNA scores. Mean scores were somewhat higher in very early biopsies and in late biopsies, increasing with time of biopsy post-transplant, but there were no strong correlations with injury or with atrophy-fibrosis. The AUCs of %dd-cfDNA for rejection were higher for MMDx than histologic rejection.

Conclusions: Results in 189 Trifecta indication biopsy reveal that dd-cfDNA% at time of biopsy is strongly related to the active ABMR processes in the biopsy but particularly NK cell genes and IFNG-induced genes.

Table 1. Top genes correlated with %dd-cfDNA in 189 in kidney biopsies (genes represented in top 30 probesets

Abstract# 323

Prospective Intensive Monitoring for Anamnestic DSA Responses Allows Near Elimination of Early Clinical AMR

M. McGowan[1], A. Bickenbach[1], A. R. Shields[2], R. R. Alloway[1], P. Brailey[1], E. Portwood[1], C. Alquist[1], A. Christianson[1], B. Abu Jawdeh[1], M. Cuffy[1], J. Kremer[2], S. Bumb[1], A. Govil[1], M. Anand[1], T. Kaur[1], E. S. Woodle[1], *[1]U Cincinnati, Cincinnati, OH, [2]Christ Hospital, Cincinnati, OH*

Purpose: Anamnestic donor specific antibody (aDSA) responses can result in severe, graft threatening antibody-mediated rejection (AMR). We hypothesized that intensive DSA monitoring (IDM) for aDSA will allow early detection/treatment thereby limiting graft injury and improving outcomes.

Methods: From May 2016 to Oct 2019 IDM for aDSA was prospectively implemented in high risk patients (pts). High risk for aDSA was defined by:1)previous transplant (txp), 2)female with preexposure to paternal antigen, 3)pretransplant DSA, 4)post-txp oliguric ATN/slow function in pts with previous HLA exposure, 5)current cytotoxic PRA >25%,peak cytotoxic PRA or calculated PRA >50%, 6)positive T or B cell flow crossmatch. IDM was performed on PTD 0,1,2,3,5,7,14,30,90,180,360. Biopsies (Bx) were obtained for aDSA>5000 or renal dysfunction. aDSA was defined as DSA within 14 posttransplant days (PTD). aDSA were treated for MFI>5000 or progressive increases or AMR on Bx.

Results: 120 pts underwent IDM: 57(47.5%) developed aDSA of whom 33/57(57.8 %) resolved without treatment. 24/57 (42%) pts were treated for aDSA. After the first 5 allograft Bx each demonstrated early/mild AMR, Bx were deemed unnecessary. After treatment, 11 (69%) pts without Bx cleared aDSA and 3 (38%) patients with AMR on Bx cleared aDSA (overall treated DSA clearance (14/24pts),57.8%). Amongst treated pts,16/24(66.7%) were treated without Bx and 8/24 (33.3%) patients had Bx meeting AMR criteria. Of treated pts, 15/24 (62.5%) had peak aDSA>5000 MFI. The strongest factor predictive of requirement for treatment was pre-existing DSA (p<0.0001). 4 pts had acute graft dysfunction due to aDSA with highest peak creatinine being 2.48 mg/dl. Overall death-censored graft survival was >98% with mean follow-up>1000 days. Deaths in treated pts were not due to overimmunosuppression. [table1]

Conclusions: 1) 47.5% of high risk pts developed aDSA, in whom 57.8% resolved with observation alone, 2) 42% of aDSA were treated with clearance in over half of pts, 3) IDM allows for early aDSA detection with avoidance of renal dysfunction in 97% of pts, 4) early aDSA detection enables avoidance of early post transplant allograft Bx,4) pretransplant DSA is the strongest predictor for aDSA requiring treatment, and 5) IDM allows early DSA detection/management with overall DCGS >98% at mean follow-up of>1000 days in a high risk population.

Abstract# 324

$CD56^{dim}CD16^{bright}$ NK Cells from Kidney Transplant Recipients with Antibody-mediated Rejection Display Increased Proliferation, Type-1 Activation and Cytotoxic Profile

E. Bailly[1], C. Macedo[1], K. Louis[1], B. Ramaswami[1], M. Lucas[1], C. Bentlejewski[1], P. Randhawa[1], A. Zeevi[1], C. Lefaucheur[2], D. Metes[1], *[1]Department of Surgery, Thomas E. Starzl Transplantation Institute, Pittsburgh, PA, [2]INSERM UMR-S976. Endothelium, Inflammation & Alloreactivity, Université de Paris, Paris, France*

Purpose: $CD56^{dim}CD16^{bright}$ NK cells are highly potent for cytotoxicity through cell-mediated cytotoxicity (CMC), antibody-dependent cell-mediated cytotoxicity (ADCC) and INF-γ production. The contribution of NK cells to antibody-mediated rejection (ABMR) injuries have been highlighted through transcriptomic analysis and immunohistochemistry of kidney and heart allograft biopsies. However, description of circulating NK cells profiles during ABMR is lacking.

Methods: Deep phenotypic analysis of circulating $CD56^{dim}$ $CD16^{bright}$ NK cells using 25-color spectral flow cytometry was implemented in 68 kidney transplant (KTx) recipients: (i) 17 donor specific anti-HLA antibody (DSA) free of ABMR, (ii) 17 DSA+ biopsy-proven mixed ABMR (DSA+ABMR+), (iii) 17 stable free of DSA/rejection, (iv) 17 T-cell mediated rejection and 17 healthy controls. Samples were analyzed at the time of rejection, of first DSA occurrence or at a matching time point in stable patients. Functional assays were performed in 8 patients from each group, consisting of 6-hours coculture of PBMC with T2 lymphoblastic cells (TAP-deficient, HLA-A2 expressor) ± anti-HLA-A2+ serum.

Results: $CD56^{dim}CD16^{bright}$ NK cells from DSA+ABMR+ patients, when compared to the other groups, significantly proliferated (Ki67+) and selectively up-regulated IL-2R/-15Rβ chain and IL-21R, suggesting their higher responsiveness to common γc cytokines that support NK cell survival/proliferation and cytotoxicity. Moreover, they co-expressed significant elevated levels of EOMES and T-bet, as well as of CD16A/FcγRIIIA-inducible CD160 and CD161/NK1.1, cytotoxicity markers that reflect their higher Type-1 activation status. Indeed, $CD56^{dim}CD16^{bright}$ NK cells from DSA+ABMR+ patients displayed increased INF-γ and TNF-α/IL-10 ratios in ADCC and CMC assays. CXCR3 overexpression was noted suggesting a higher migration potential towards inflamed tissues.

Conclusions: Significant NK cell phenotypic and functional changes occur during ABMR with potential involvement to allograft injury. Early detection of proliferating, activated, cytotoxic $CD56^{dim}CD16^{bright}$ NK cells in the blood of patients with ABMR could help for timely therapeutic intervention.

Abstract# 325

The Relationship Between Health Literacy and Adverse Outcomes After Kidney Transplantation

E. Lorenz, T. Petterson, C. Schinstock, W. Sanchez, K. Yost, *Mayo Clinic, Rochester, MN*

Purpose: Limited health literacy has been associated with a decreased likelihood of listing for transplant and an increased risk of waitlist mortality among kidney transplant candidates. However, little is known about the impact of health literacy on post-transplant outcomes. The objective of this study was to examine the relationship between health literacy and outcomes after kidney transplantation.

Methods: We assessed health literacy in 691 adults undergoing kidney transplant evaluation at our center between 6/2015 and 3/2017 using the 4-item Brief Health Literacy Screening Tool (BRIEF) as part of a pilot educational intervention. Health literacy was defined as limited if the BRIEF score was ≤ 12, marginal if 13-16, and adequate if ≥ 17. Health literacy was examined using Cox proportional hazards regression, logistic regression, and linear regression modeling.

Results: During follow-up, 298 adult patients underwent kidney transplant alone at our center. Mean age was 53 ± 14 years, 60% were men, and 78% received living donor kidney transplants. Overall, 25% of the patients (n=74) had limited or marginal health literacy. Limited or marginal health literacy was associated with diabetes and a history of a high school education or less but not with dialysis dependency, donor type, or donor age. No relationship between patient health literacy and post-transplant hospital length of stay, rehospitalizations, or acute rejection was observed. However, marginal patient health literacy was significantly associated with renal allograft failure and death (HR 5.4, CI 1.8-16.1, p=0.003 and HR 7.2, CI 1.7-29.9, p=0.008, respectively). The relationship between marginal health literacy and renal allograft failure and death appeared to be independent of age, gender, or diabetes. Further analysis of the health literacy questions suggest that self-reported need for help with reading materials from doctors or nurses, such as instructions for medicine, was associated with renal allograft failure and with death.

Conclusions: Limited or marginal health literacy was observed among one quarter of patients receiving kidney transplants at our center. Marginal health literacy, specifically self-reported difficulty reading written materials, appeared to be significantly associated with renal allograft failure and death following kidney transplantation. Efforts to improve post-transplant communication may improve outcomes in kidney transplant recipients with marginal health literacy.

Abstract# 326

Evolving Trends in Risk Profiles and Outcomes in Older Adults Undergoing Kidney Re-Transplantation

S. Sandal[1], J. Ahn[2], M. Cantarovich[1], N. Chu[2], D. Segev[2], M. McAdams DeMarco[2], *[1]McGill University, Montreal, QC, Canada, [2]Johns Hopkins University, Baltimore, MD*

Purpose: The half-life of a kidney transplant (KT) is 8-12 years, and a significant proportion of patients end up with graft loss at age ≥65 years. Indeed, graft loss is one of the leading causes of kidney failure. While there has been a significant increase in older adults receiving their first KT over the past three decades, it is not known if there were parallel trends in re-KT. Thus, we aimed to characterize the trends, changing landscape, and outcomes of re-KTs in older adults.

Methods: Among the 44,149 older kidney-only recipients (1995-2016) in the Scientific Registry of Transplant Recipients, we identified 1,743 who were undergoing re-KT. We analyzed trends by eras (1995-2002, 2003-2014 and 2015-2016) and outcomes (death-censored graft failure (DCGF), all-cause graft failure (ACGF), death) using Kaplan-Meier estimators.

Results: Among all older patient undergoing KT, only 3.9% were re-KT. However, over time this proportion increased significantly (1995-2002: 2.7%, 2003-2014: 4.2%, 2015-2016: 5.7%, p<0.001). The median age at re-KT (1995-2002: 67, 2003-2014: 68, 2015-2016: 68, p=0.04) and the lifetime of the first transplant, i.e. duration of exposure to immunosuppression (1995-2002: 2.7, 2003-2014: 6.5, 2015-2016: 8.6 years, p<0.001) have also increased significantly. Older re-KT patients are more likely to have a PRA of 80-100% (1995-2002: 22.0%, 2003-2014: 32.7%, 2015-2016: 48.7%, p<0.001), spend longer time on dialysis after first graft failure (1995-2002: 1.4 years, 2003-2014: 1.5 years, 2015-2016: 2.2 years, p=0.003), be living with assistance (1995-2002: 9.0%, 2003-2014: 12.6%, 2015-2016: 24.8%, p<0.001), undergo donations after circulatory death (1995-2002: 1.1%, 13.4%, 19.5%, p<0.001), and have an older donor (1995-2002: 40 years, 2003-2014: 43 years, 2015-2016: 43.5 years, p=0.04). Despite this, the 3- and 5-year cumulative incidence of death, DCGF and ACGF have decreased significantly over time (Figure 1).

Conclusions: In older adults with re-KT, the 3-year cumulative incidence for death, DCGF, and ACGF has decreased by >50% in the past two decades despite a widening risk profile. Yet, they represent a small fraction of the total KTs performed. It is encouraging to see that this proportion has doubled over the past two decades, however, there are likely significant barriers to re-KT in older adults. Factors associated with these trends need to be better understood to inform clinical practice and policy.

Figure 1: Cumulative incidence of (a) death, (b) death-censored graft failure, and (c) all-cause graft failure after re-KT, stratified by three eras of interest in re-KT (1995-2002, 2003-2014, and 2015-2016)

Abstract# 327

Journey to Transplant: A Pilot Feasibility Trial of a Virtual Counseling Intervention for Patients and Their Social Support Networks to Improve Access to Kidney Transplant

A. Hart[1], R. Edpuganti[2], H. D'Cunha[2], S. Kurschner[2], W. T. McKinney[1], A. Matas[1], R. Patzer[1], S. Chu[1], M. Bruin[1], M. Partin[1], *[1]Hennepin Healthcare, University of Minnesota, Minneaplis, MN, [2]Hennepin Healthcare Research Institute, Minneaplis, MN*

Purpose: Home counseling interventions have shown promise in increasing rates of kidney transplant, but are challenging to implement. We piloted a structured but individualized virtual counseling intervention, including a risk calculator for outcomes on the waitlist, for a candidate with their social support network (SSN).

Methods: Transplant candidates, defined as patients moving beyond the initial evaluation, were recruited from 2 centers in Minneapolis. The study was informed by a patient and family advisory committee comprised of 12 kidney transplant candidates, recent recipients, and family members. The 1.5-hour virtual counseling session was designed using Intervention Mapping to incorporate focus group data on patient and SSN needs into an intervention grounded in behavior change theory. The intervention was conducted by a nephrologist and consists of 3 parts: 1) standardized education about transplant options, pros and cons, 2) review of the patient's calculated likely outcomes on the deceased donor waitlist, and 3) addressing barriers and needs specific to that patient.
Results: 8 kidney transplant candidates, along with 19 (1-4 each) of their SSN members, were randomized to the intervention, and 5 candidates to controls. Half of social support network members reported getting all their information from the patient. Both patients and SSN members had knowledge gaps prior to the intervention; e.g. 67% of patients and 57% of SSN members did not know that living donor kidneys usually last longer than deceased donor kidneys. After the intervention, participants reported having a better understanding of options such as increased infectious risk kidneys in light of likely outcomes on the list, and felt more empowered. The outcomes calculator was emotional but well-received by SSN members in particular. SSN members reported better understanding their patient's disease and how to help the patient get transplanted. Participants gave useful feedback on how to improve the intervention.
Conclusions: A virtual group counseling session with patients along with their SSN is feasible in different transplant center settings and well-received by patients and SSN members. Recruitment will begin at a third center in Atlanta, GA to further assess implementation barriers. A future randomized controlled trial will determine whether the intervention increases rates of kidney transplant.

Abstract# 328

Understanding Transplant Decision Making Concerns for African, Caribbean and Black Canadian Patients with End-Stage Kidney Disease

N. Singh[1], A. Wasim[1], W. Hajjar[1], K. Mohan[1], N. El-Dassouki[1], H. Habbal[1], L. Angarso[1], A. Dychiao[1], S. Macanovic[1], A. D. Waterman[2], I. Mucsi[1], *[1]University Health Network, Toronto, ON, Canada, [2]David Geffen School of Medicine, UCLA, Los Angeles, CA*
Purpose: Compared to White Canadians, African, Caribbean and Black (ACB) Canadians with end stage kidney disease (ESKD) are less likely to receive a living donor kidney transplant (LDKT). We explored factors associated with kidney transplant (KT) decision-making, specifically the weight patients give to perceived pros and cons for KT decisions.
Methods: Using the Transplant Decisional Balance survey, patients rated the importance of perceived pros and cons to KT decision-making from 1-5 ("not important"-"extremely important"). In a cross-sectional convenience sample of adults with ESKD in Toronto, ethnicity was self-identified. Individual ratings of pro/con items were summed to yield LDKT and deceased donor KT (DDKT) pro/con scores. Individual scale items were also examined: dichotomized (not/slightly/moderately vs very/extremely important) and their independent association with ethnicity analyzed in multivariable logistic regression.
Results: Among the 590 participants (mean[SD] age 57[13] years, 62% male), 24% were ACB, and 42% were White. ACB participants were less likely to have >12 years of education (44% vs 64%, p<0.001) and incomes of >$30K/year (39% vs 71%, p<0.001) compared to White participants. The summed LDKT scores and DDKT pro scores were similar between the groups. However, ACB participants rated perceived DDKT con scores (12[5,16] vs 9[5,13]; p=0.002) higher than Whites. In univariable analysis, ACB participants were more likely to indicate that perceived "trouble paying for medications" (OR, 2.28 [95% CI: 1.44, 3.59), "taking many medications post-transplant" (OR, 2.47 [95% CI: 1.69, 4.42]), "pain from surgery" (OR, 1.83 [95% CI: 1.11, 3.11]) and potential "health problems due to transplant" (OR, 1.83 [95% CI: 1.11, 3.02) were important to their decision about transplant compared to Whites. After adjusting for sociodemographic variables, comorbidity and transplant knowledge at baseline, the importance of "taking many medications post-transplant" (OR, 2.11 [95% CI: 1.27, 3.51) and "trouble paying for medications" (OR, 1.72 [95% CI: 1.02, 2.90) remained associated with ACB ethnicity in the final logistic regression model. However these associations were not significant after adjusting for transplant knowledge for "pain from surgery" (OR, 1.56 [95% CI: 0.89, 2.72]) and "health problems due to transplant" (OR, 1.45 [95% CI: 0.89, 2.36).
Conclusions: Concerns about the quantity of post-transplant medications and anticipated financial strain are associated with KT decisions among ACB Canadians with ESKD compared to Whites. Further qualitative research is needed to better understand the reasons for these ethnicity-specific differences in decision making.

Abstract# 329

Depressive Symptoms and Listing for Kidney Transplantation

X. Chen, N. Chu, P. Sharma Basyal, W. Vihokrut, D. Crews, D. Brennan, S. Andrews, T. Vannorsdall, D. Segev, M. McAdams DeMarco, *Johns Hopkins University School of Medicine, Baltimore, MD*
Purpose: Among patients with kidney failure, depressive symptoms are common and may be a barrier to completing the complex process of kidney transplantation (KT) evaluation and listing. We sought to explore the burden of depressive symptoms among kidney failure patients being evaluated for KT and the impact of depressive symptom severity on listing for KT.
Methods: In a prospective cohort study of 3,727 adult patients being evaluated for KT (1/2009-3/2020), depressive symptoms were measured using the 20-item Center for Epidemiologic Studies-Depression (CES-D) Scale and the severity of depressive symptoms was categorized as: none:0; minimal:1-15; mild:16-20; moderate:21-25; severe:26-60. Time to listing by depressive symptoms severity was estimated using Cox Proportional Hazards models, adjusting for demographic, socio-economic, and health factors.
Results: Depressive symptoms were reported by 18.4% of patients. Younger patients more frequently reported depressive symptoms (age 18-49:22.8%; 50-64:19.1%; ≥65:11.7%; p<0.001). Patients with severe symptoms were 31% less likely to be listed than those without symptoms (hazard ratio [HR]=0.69, 95% confidence interval [CI]=0.56-0.85); the likelihood of being waitlisted decreased with increasing CES-D score (HR for every 5-point worsening=0.94, 95% CI=0.92-0.97).
Conclusions: Kidney failure patients, particularly younger patients, have a high burden of depressive symptoms at KT evaluation. Regardless of age, patients with depressive symptoms are less likely to be listed for KT. Transplant centers should screen at evaluation to identify patients who would benefit from interventions to reduce depressive symptoms.

Figure: Unadjusted cumulative incidence of kidney transplantation (KT) listing by severity of depressive symptoms among patients being evaluated for KT (n=3,727). CES-D score ranges 0-60 points. Severity of depressive symptoms was categorized as: none, 0 point; minimal, 1-15 points; mild, 16-20 points; moderate, 21-25 points; severe, 26-60 points.

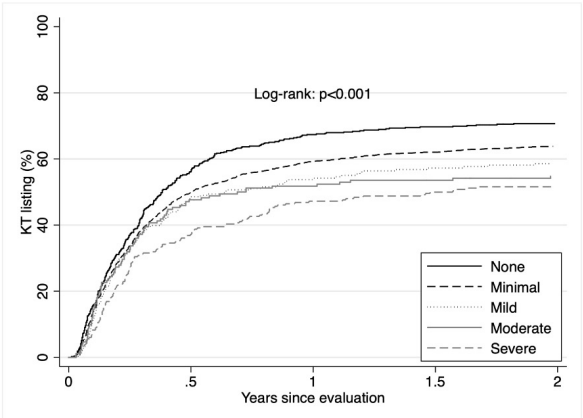

Table: Chance of listing by severity of depressive symptoms among patients being evaluated for kidney transplantation (KT). Adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs) are presented from adjusted Cox Proportional Hazards models. Associations that are statistically significant at p<0.05 are bolded.

	Patient factor adjusted model (n=3,113) aHR (95% CI)	Patient and neighborhood factor adjusted model (n=3,041) aHR (95% CI)
Severity of depressive symptoms		
No symptoms	Reference	Reference
Minimal symptoms	**0.82 (0.73, 0.92)**	**0.85 (0.75, 0.96)**
Mild symptoms	**0.70 (0.57, 0.86)**	**0.74 (0.60, 0.91)**
Moderate symptoms	**0.74 (0.58, 0.94)**	0.79 (0.62, 1.00)
Severe symptoms	**0.62 (0.51, 0.76)**	**0.69 (0.56, 0.85)**
Continuous Score (5 points worse)	**0.94 (0.91, 0.96)**	**0.94 (0.92, 0.97)**

Abstract# 330

Multistep Algorithm to Achieve Weight Loss Goal in Advanced Stage Obesity Kidney Transplant Candidates: A Single Center Preliminary Report

A. Shah, J. Galpern, L. Castaldo, P. Touhy, M. Thomas, A. Aaron, M. Fruscione, L. Dageforde, N. Elias, *Transplant Surgery, Massachusetts General Hospital, Boston, MA*

Purpose: Obesity causes and complicates glomerulonephritis and chronic kidney disease (CKD) leading to end stage renal disease (ESRD). Kidney Transplantation (KT) improves ESRD patients' survival and quality of life, but to a lesser extent if obese given increased allograft failure and mortality risks. At our center, obesity is a major basis for inactive status. Obesity management in CKD has not been standardized.

In 2018, counseling and follow up of patients with obesity (BMI>35) yielded minimal change. We have since launched a multistep weight loss intervention algorithm and aim to determine its effectiveness along with identification of major barriers for KT candidates with obesity (KTCwO).

Methods: Since April 2019, newly referred KTCwO (BMI>38) are enrolled with informed consent into IRB approved prospective study-. A structured protocol initiated by registered dietician and transplant surgeon at initial visit with nutrition/motivation/frailty assessments, weight loss education and establishment of goal weight loss >5% over 6-month period to achieve BMI<38, counseling on food regimens, home tracking/app devices, and introduction to weight center with referrals. Follow up consisted of monthly phone calls with intervention checkpoints at 6 and 12 months.

Results: Our initial 2018 support process review yielded 87 KTCwO. 36 of them achieved minimal weight loss while 22 gained weight, with no change in percent of wait list patients inactive due to obesity. Since the multistep algorithm introduction, 28 listed inactive KTCwO enrolled. 11 of them with less than 6-month follow up were excluded from analysis. 7/17 patients have achieved weight loss with >2 follow up encounters since initial evaluation. 3 patients have implemented diet and exercise regimens and 4 patients have been referred to weight center. Of the weight center referrals, one patient is managed with medication and three have been referred for bariatric surgical evaluations.

Conclusions: While in preliminary stages, multidisciplinary intervention initiation with assistance of weight center has resulted in KTCwO benefit. We recognize the limitations of time and power in our data along the ongoing identification of barriers in enrolled patients. Continued follow up with individualized checkpoint interventions and accrual of more patients will yield promising outcomes for KTCwO.

Abstract# 331

Challenges and Stressors of COVID-19 Kidney and Transplant Patients: A Mixed Methods Study

Y. A. Iraheta[1], A. L. Murillo[2], E. H. Wood[1], S. M. Advani[3], R. Pines[4], A. D. Waterman[1], *[1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]Terasaki Institute, Los Angeles, CA, [3]National Human Genome Research Institute (NIH), Bethesda, MD, [4]Santa Barbara Cottage Hospital, Santa Barbara, CA*

Purpose: To assess the unique needs of at-risk kidney and transplant patients and their caregivers during COVID-19, we established a telephone Listening Center enabling them to share about challenges seeking care, common stressors, and opportunities for healthcare delivery improvement.

Methods: We conducted a mixed methods study where participants answered open and closed-ended questions about their health, financial, and emotional challenges during COVID-19. Data from open-ended questions were analyzed using thematic analysis. Descriptive statistics were run for quantitative items to explore frequencies of COVID-related stressors.

Results: The 111 participants varied by race/ethnicity [Hispanic (29%), White (24%), Asian (23%), Black (23%), Other (1%)], with most being English-speakers (85%). Many participants experienced health, financial, or emotional COVID-19 related stressors (Table). Patients reported severe limitations due to need for social distancing, inability to go to overcrowded medical settings and public spaces, and difficulty receiving assistance replacing in-home dialysis supplies, childcare support, or help with home repairs. Using the Patient Health Questionnaire (PHQ4), 30% of participants reported feeling depressed and 35% reported feeling anxious on several to most days. Participants sought emotional support from family, friends, and communities of faith using facetime and zoom. Patients wanted a centralized place to receive COVID-19 updates, recommendations for safe activities, flexibility to choose online or in person medical visits, and regular follow up from their kidney/transplant specialists related to COVID-19.

Conclusions: Over 40% of patients reported fear, frustration, loneliness, and postponed medical visits due to COVID-19. Needs-based interventions include mental health resources, education, and support for care transitions may be helpful, particularly as the pandemic continues.

Table. COVID-19 Stressors

Health Stressors	% Yes
Less physically active due to staying at home	52.82%
Postponed medical visit(s)	44.14%
Postponed transplant-related appointments	20.72%
Difficulty obtaining medications	9.91%
Financial Stressors	
Working from home	31.53%
Job loss/reduced work hours	26.19%
Emotional Stressors	
Frustration about the limitations to life due to COVID-19	60.36%
Fear of getting COVID-19	60.36%
Loneliness due to social distancing	39.64%
Lost a family member/friend due to COVID-19	16.82%

Abstract# 333

Early Transplant Education Increases CKD 3-5 Patients' Knowledge and Informed Decision-Making About Chronic Kidney Disease and Living Donor Kidney Transplant

A. D. Waterman[1], S. H. Kawakita[2], B. Dub[3], Y. A. Iraheta[1], A. L. Murillo[2], T. Menser[4], B. Mittman[3], *[1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]Terasaki Institute, Los Angeles, CA, [3]Research and Evaluation, Kaiser Permanente, Pasadena, CA, [4]The Houston Methodist Research Institute, Houston, CA*

Purpose: Early education about chronic kidney disease (CKD) and living donor kidney transplant (LDKT) outside of transplant centers is inconsistent, with patients in CKD 3 and 4 and ethnic/racial minorities even less likely to receive it. Improvements in transplant educational delivery for early-stage CKD patients are needed.

Methods: We conducted a prospective, parallel arm randomized controlled trial (RCT) with 971 patients varying by CKD Stage [3 (41.2%); 4 (34.4%), and 5 (24.4 spoken at Kaiser Permanente Southern California (KPSC). Patients were stratified by Stage, race/ethnicity, and primary language spoken and randomized to: (1) Explore Transplant@Home (ET), a supplementary video-guided, print and text-based education intervention delivered remotely or (2) standard of care KPSC transplant education (SOC). We fitted multilevel random effect models and compared changes in outcomes by condition 6 months post-baseline. Interactions between treatment condition and each stratifying variable were assessed.

Results: CKD patients were diverse [White (22.2%), Black (18.4%), Asian (9.6%); English-speaking Hispanics (21.7 %), Spanish-speaking Hispanics: (28.0 %)]. Compared to SOC, patients receiving ET were twice more likely to make informed decisions about pursuing LDKT than those receiving SOC (1.99 [1.35, 2.92] p<.001). Increases in CKD symptom knowledge and transplant knowledge were also observed for the ET group at 6 months (p < 0.001) (Figures). There were heterogeneity of treatment effects for informed decision-making by CKD Stage (p = 0.067) and for DDKT self-efficacy by primary language spoken (p = 0.059).
Conclusions: With this study showing promise in improving knowledge for earlier stage CKD patients and Spanish-speakers much earlier through ET, interventions to increase preemptive transplantation could utilize these educational methodologies to increase LDKT rates.

Liver

Post Liver Transplant Management and Complications

Abstract# 334

A Meta-Analysis of Endoscopic Stents in the Treatment of Anastomotic Biliary Strictures After Liver Transplantation

F. Zhou[1], M. Mieth[1], C. Rupp[2], A. Mehrabi[1], A. Nickkholgh[1], *[1]Department of General, Abdominal and Transplant Surgery, University of Heidelberg, Heidelberg, Germany, [2]Department of Internal Medicine, University of Heidelberg, Heidelberg, Germany*

Purpose: Biliary strictures (BS) are common after orthotopic liver transplantation (OLT). The treatment of choice is endoscopic retrograde cholangiopancreatography (ERCP). Multiple plastic stents (MPS) have been widely; covered self-expandable metallic stents (SEMS) have been invented subsequently to reduce the need for stent replacements and to reduce the intervention times. Biodegradable stents (BDS) have been recently introduced. Few studies have included the comparison of all three modalities. This study aims to compare results from the use of MPS and BDS to treat BS after OLT to recent outcomes after BDS.
Methods: PUBMED and EMBASE databases. Search for available RCTs and clinical trials to compare the efficacy and safety of MPS, SEMS and BDS in ABS after orthotopic liver transplantation(OLT). Primary outcomes were the resolution, and the recurrence of BS, while secondary outcomes were adverse events and number of procedures performed. Pooled estimates were calculated using random-effects models.
Results: Seven studies (481 patients) included the comparison between MPS (184 patients) and SEMS (297 patients). There was no significant difference between MPS and SEMS regarding BS resolution (OR=0.97, 95%CI: 0.59-1.58, p=0.91), recurrence (OR=1.17, 95%CI: 0.50-2.74, p=0.73), successful treatment with initial protocol (OR=1.69, 95%CI: 0.85-3.39, p=0.14). SEMS reduced the number of ERCP sessions needed to achieve stricture resolution (p<0.0001). SEMS, however, had significantly higher complications during treatment (OR=2.3,95%CI:1.41-3.75, p=0.0009). Only four descriptive studies were found using BDS on total of 55 patients to treat BS after OLT with no control group. Using Stata software comparison,the stricture resolution rate in BDS seems to be lower compared to both SEMS and MPS groups (Figure1-3), with lower rate of complication compared SEMS and MPS (Figure 4-6).
Conclusions: Compared to MPS,SEMS provides shorter operation time and similar success rate,reducing the number of ERCP session to achieve stricture resolution, but have higher complication rate during treatment. BDS seems to have lower stricture resolution rate and complication rate during treatment than SEMS and MPS.

Abstract# 335

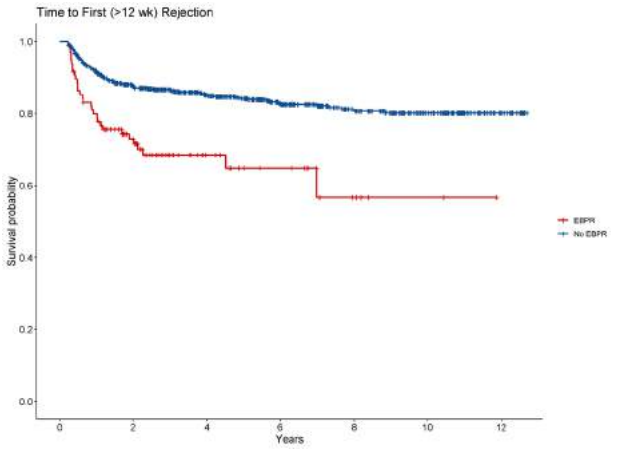
Effect of Early Biopsy-Proven Rejection on Liver Transplant Outcomes

D. D. Aufhauser, N. Marka, L. Stalter, G. Levenson, D. Al-Adra, D. P. Foley, *Surgery, University of Wisconsin, Madison, WI*

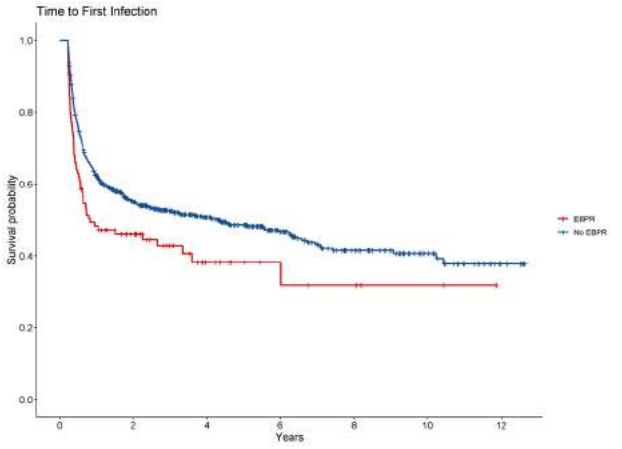
Purpose: Existing literature offers conflicting conclusions about whether early acute cellular rejection influences long-term outcomes in liver transplantation.
Methods: We retrospectively collected donor and recipient data on 813 adult, first-time liver transplants performed at a single center between 2009 and 2019. We divided this population into two cohorts based on the presence of early biopsy-proven acute cellular rejection (EBPR) within the first 12 weeks post-transplant and compared outcomes (overall survival, death censored graft survival (DCGS), infection and long-term rejection rates) between the groups. Kaplan-Meier estimates were used to assess time to first event with p value < 0.05 for significance.
Results: Of the 813 liver transplants, 97 (12%) met inclusion criteria of EBPR. Donor and recipient characteristics did not differ between patients with and without EBPR (Tables 1).

Characteristic	Early biopsy-proven rejection (n=97)	No early rejection (n=716)	p-value
Recipient age	54 (52-57)	55 (55-56)	0.41
Recipient female	28% (27)	30% (231)	0.41
Recipient BMI	31 (29-32)	30 (29-31)	0.36
Use of induction agent	15% (15)	19% (133)	0.57
Donor age	45 (43-48)	45 (44-46)	0.68
Donor female	43% (42)	39% (276)	0.37
Donor BMI	29 (28-31)	28 (28-29)	0.21

Recipients with EBPR had similar overall survival compared to patients without EBPR (p=0.29), but had inferior one year death-censored graft survival (95.8% for EBPR vs. 98.7% for no EBPR, p<0.05). EBPR was also associated with decreased time to first episode of late (>12 weeks post-transplant) rejection (p<0.0001, Fig 1).



Recipients with EBPR had increased rates of bacterial and viral infection (p<0.05, Fig 2).



Conclusions: EBPR after liver transplant is associated with inferior death-censored graft survival, increased susceptibility to late rejections, and increased vulnerability to infection. Identifying strategies to mitigate EBPR may lead to improved long-term outcomes after liver transplantation.

Abstract# 336

The Predictive Factors of Survival in Re-listed Patients Who Received Initial Liver Transplants Using Donation After Circulatory Death Grafts

Y. Fouda, A. Moro, J. Mcvey, D. Firl, M. Fujiki, D. Teresa, F. Aucejo, C. Quintini, C. H. Kwon, K. Hashimoto, B. Eghtesad, K. Narayanan Menon, C. Miller, K. Sasaki, *Cleveland Clinic, Cleveland, OH*

Purpose: The inherent risk of livers from donors after circulatory death (DCD) is well known such as primary non-function (PNF) and increased rates of biliary complications. Due to the high graft dysfunction rate in a relatively early phase after the initial liver transplant (LT), many patients who received DCD organ needs re-transplant and were re-listed. However, the clinical characteristics and prognostic factors of those re-listed patients have not been fully elucidated.

Methods: Adult patients who received DCD LT between 2002 and 2019 were identified from the UNOS database. Predictors of drop out due to too sick/death in re-listed patients were examined using Fine-Gray model. Predictors of overall survival (OS) after re-LT were examined using Cox regression model.

Results: Among 5734 patients, 1332 patients died without re-listing (23.2%) and 712 patients were re-listed after initial LT (12.4%). Among 711 re-listed patients, 480 patients received second LT (8.4%) and 128 patients were removed from list because of too sick/death (2.2%). Among 480 re-LT patients, 187 patients (39.0%) died after re-LT. The median days between first LT and re-listing was 99 days (IQR: 12-331). The distribution of initial graft lost causes/percentage of re-LT patients/median waiting time form re-listing are summarized (Table). In re-listed patients, older recipient (> 50) and graft loss caused by primary non-function or HAT/PVT were predictors of dropout. In re-LT patients, younger recipient (≤50) at first-LT, male, lower MELD at time of second-LT, and younger donor age were favorable factors of patient survival after LT. The OS from first-LT was compared according to recipient age in patients who were re-listed and not re-listed. The 5-years survival rate in younger patients was 5.0% better in patient without re-listing, which was much higher in re-listed patients (14.9%) (Figure).

Conclusions: Nearly 10% of DCD LT patients received re-LT mainly due to complications related to DCD organs. Younger recipient age is an important factor to survive in case patients need re-listing after LT using DCD organ.

Cause of Graft Loss

Median (IQR)	PNF (n=180)	HAT/PVT (n=70)	IC (n=316)	Miscellaneous (n=146)	P

Abstract# 337

Molecular Assessment of Fibrosis and Steatohepatitis in the INTERLIVER Study

K. S. Madill-Thomsen[1], P. F. Halloran[1], &. the INTERLIVER Study Group[2], *[1]Alberta Transplant Applied Genomics Centre, Edmonton, AB, Canada, [2]., ., AB, Canada*

Purpose: We previously reported a molecular system for assessing rejection in liver transplants and recently expanded this system to assess injury. Fibrosis is associated with worse long-term liver graft and patient survival, while steatohepatitis is a leading cause for liver transplantation and frequently recurs post-transplant. We examined the molecular changes associated with these conditions.

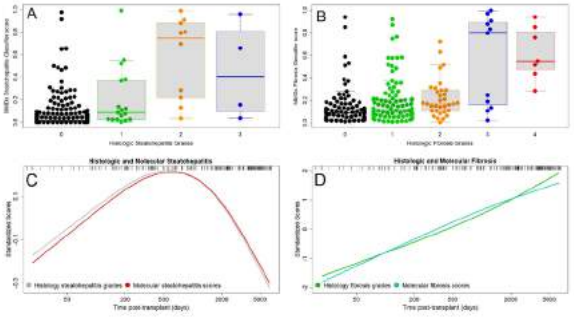
Methods: We used gene expression microarrays to study 337 liver transplant indication biopsies from 13 international centers with standard-of-care (SOC) clinical and histologic data. Molecular classifiers were trained on binary histology-based classes (fibrosis grades <=1 vs >1, steatohepatitis grades 0 vs >0); scores were represented by the median of an ensemble of machine learning estimates. Top transcripts for pathway analysis and volcano plots used the same class comparisons. Splines assessed relationships to time post-transplant. Statistical analyses were done in R.

Results: Steatohepatitis was predicted by a classifier trained on histologic steatohepatitis (AUC=0.83). Fibrosis was predicted by a classifier trained on histologic fibrosis (AUC=0.74). Classifier scores increased with histologic grades (Figure 1A-B). Steatohepatitis grades/scores peaked 2-5 years post-transplant; fibrosis grades/scores increased linearly over time as visualized in splines (Figure 1C-D).

Volcano plots visualized transcripts associated with histologic fibrosis and steatohepatitis. Top transcripts increased and decreased in expression in steatohepatitis biopsies were associated with metabolism e.g. TMEM154 (Figure 1E). In fibrosis, immunoglobulin transcripts were increased e.g. IGK, as were transcripts previously associated with hepatic fibrosis in native livers e.g. stathmin2/STMN2, sodium leak channel/NALCN, papilin/PAPLN (Figure 1F). Pathway terms showed metabolic dysregulation in steatohepatitis, and immune cell activity and matrix structure in fibrosis (Figure 1G).

Though DSA testing was limited, we found no significant relationship between DSA and fibrosis.

Conclusions: Molecular fibrosis was present in 45% of biopsies, and increased over time. Molecular steatohepatitis affected 55% of biopsies, peaking 2-5 years post-transplant before declining. We found no significant relationship between DSA and hepatic fibrosis in this population. Quantitative scores for steatohepatitis and fibrosis from molecular classifiers provide objective measurements with potential to guide management while offering mechanistic insights.



G Top 10 GO Terms from pathway analysis on top 300 unique transcripts (increased and decreased, by p value) associated with histologic steatohepatitis and fibrosis sorted by Spearman correlation coefficient absolute value.

Abstract# 338

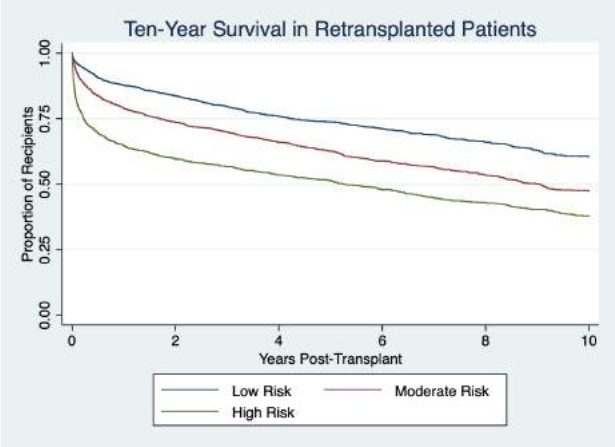
Predictive Index for Liver Retransplantation

C. Christmann, G. Handing, M. McDonald, A. Anand, S. Keeling, N. T. Galván, R. Cotton, C. O'Mahony, J. Goss, A. Rana, *Baylor College of Medicine, Houston, TX*

Purpose: Given the increase in demand for donor livers, it has become more critical than ever to predict mortality in order to identify the best possible use of a donor organ. This is particularly true in cases involving retransplantation, which is increasing in prevalence despite overall poorer outcomes. Our aim was to develop a predictive index for liver retransplantation to predict mortality based on donor and recipient characteristics.

Methods: Using the OPTN database, we performed univariate and multivariate analysis on 5,183 liver retransplantations to identify independent donor and recipient risk and protective factors for post-transplant mortality. This retrospective analysis was used to create a weighted score that can be used to predict post-retransplant mortality.

Results: We found 14 factors to be significant and weighted them according to their odds ratio to generate an r-SOFT (Retransplant Survival Outcomes following Liver Transplantation) score with a C-statistic of 0.705. We then generated a Kaplan-Meier curve to estimate survival at ten years post-retransplant, stratifying patients into low-, moderate-, and high-risk groups by tertile. The most significant risk factors for post-transplant mortality were hemodialysis prior to transplant and poor functional status, while the most significant protective factors were a short cold ischemia time and recipient age below 30.



Conclusions: This scoring system can be used to predict mortality post-transplant for patients who have already received a liver transplant. It uses criteria from both the donor and the recipient in order to aid decision-making for patients requiring a second liver and identify transplant patients at particularly high risk.

Abstract# 339

Is There a Role for Donor-Specific Antibody Testing in Simultaneous Liver-Kidney Transplantation? A Single Center Analysis of Outcomes

A. Das, A. Barbetta, D. Remulla, C. Goldbeck, T. Maw, J. Kim, *University of Southern California, Los Angeles, CA*

Purpose: Simultaneous liver-kidney transplantation (SLKT) has grown exponentially since its conception in the 1960's. The role for donor specific antibody (DSA) testing in SLKT is unclear. The purpose of this single-center study was to assess the impact of DSA testing on outcomes including rate of rejection, graft survival, and patient survival following SLKT.

Methods: Patients who underwent primary SLKT between 2008-2018 at our center were reviewed retrospectively. DSA testing has only recently been integrated into our protocol. Demographic and clinical characteristics were summarized using mean and standard deviation for continuous variables and counts with percentages for categorical variables. Patient and graft survival were calculated using the Kaplan-Meier method.

Results: A total of 149 patients met inclusion criteria. The mean age at transplant was 55.4 ±10.4 years, 92 (61.7%) were males, and the majority were Hispanic (55.7%). The most common liver diagnosis leading to transplant was alcoholic liver disease (22.1%) followed by viral hepatitis (17.4%). 57 (38.3%) patients experienced at least one episode of acute liver rejection, mostly mild (44.6% RAI=3). However, only 16 patients had kidney rejection, with 3 having at least one episode of antibody mediated rejection. Overall, 61 patients were screened for DSA post-transplant, and 28 (45.9%) had at least one DSA detected. There were 11 patients with both liver and kidney rejection, of whom 6 were DSA positive. At the time of the last follow-up, 79.2% of patients were alive with a mean overall survival of 9.3 years (95% CI 8.5-10). Kidney and liver graft survival were 75.2% (mean overall graft survival 8.7 years, 95% CI 7.9-9.5) and 75.8% (mean overall graft survival 9 years, 95% CI 8.2-9.8) respectively. There was no difference in graft and patient survival when we stratified by either DSA test performed or DSA status (Fig 1).

Conclusions: These data demonstrate that SLKT is associated with excellent long-term patient and allograft survival. Moreover, whether or not DSA was tested or detected, a low rate of kidney rejection was observed. In our experience, testing for DSA does not impact SLKT outcomes.

Abstract# 340

High and Low Frequency Domino Liver Transplantation Centers Demonstrate Similar Outcomes

J. Panichella, H. Resweber, H. Curtis, K. Nguyen, A. Di Carlo, S. Karhadkar, *Temple University School of Medicine, Philadelphia, PA*

Purpose: For patients with transthyretin (TTR) Amyloidosis, the only disease modifying treatment is an orthotopic liver transplant. However, because of the nature of this disease, the patient's liver can simultaneously be donated to another patient. Current research already demonstrates the success of Domino Liver Transplants (DLTs) and points to the benefit of this procedure in increasing the donor organ pool for those in dire need of a transplant. However, the use of DLTs in many transplant centers has been limited. Trepidation over outcomes and complications in low frequency DLT centers has deterred hospitals from performing this procedure. This study analyzes the performance outcomes (of the DLT recipient) of transplant centers that perform a high number of DLTs to those that perform less DLTs.
Methods: United Network for Organ Sharing (UNOS)/Organ Procurement and Transplantation (OPTN) Standard Transplant Analysis and Research (STAR) database was queried and analyzed with SPSS version 26 IBM. Whole liver domino patients were extracted from the living donor dataset for transplants performed between April of 1996 and January of 2018 (n=193). Quantitative data was recorded as a mean with a standard deviation, while qualitative data is recorded as a frequency and percentage of the population queried. A Kaplan-Meier curve was also performed. High frequency DLT centers were defined as those who have performed more than 5 DLTs — above the 75th percentile for DLTs performed in transplant centers nationally.
Results: Overall outcomes between low and high frequency DLT centers were very similar. There was no difference between types of centers in cardiac, respiratory, or renal failure as a cause of death. There was no difference in functional status at the last follow-up between the two types of centers. The Kaplan-Meier curve shows the allograft survival is similar between the two groups. Graft status at the time of the last follow-up showed 91.7% of grafts functioning in the low frequency centers compared to 86.5% of grafts functioning high frequency centers. Acute rejection (1.5% high frequency versus 1.6% low frequency) and chronic rejection (1.5% high frequency versus 1.6% low frequency) were shown to be a similarly low value between the groups.
Conclusions: The outcomes of low frequency DLT centers are very similar— if not better— than those of the high frequency DLT centers. This encourages hesitant transplant centers to perform more DLTs without the fear of outcomes or complications. Continued analysis to show significance are underway.

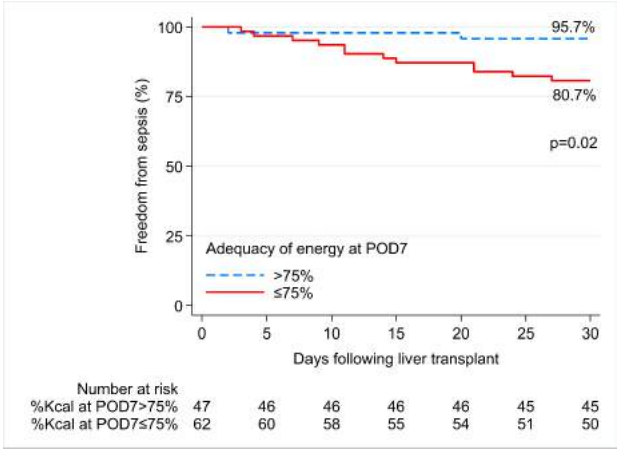
Abstract# 341

Nutritional Inadequacy is an Independent Predictor of Sepsis Post-liver Transplantation

J. V. Nolte Fong, M. Elshawwaf, L. W. Moore, E. A. Graviss, D. T. Nguyen, R. Angell, A. Uosef, T. Hirase, C. M. Mobley, R. Ghobrial, *Houston Methodist Hospital, Houston, TX*

Purpose: Malnutrition is universally prevalent in liver transplant (LT) recipients in the perioperative setting. Malnutrition contributes to post-LT complications, such as sepsis. We aimed to determine the association between perioperative nutritional inadequacy (NI) and sepsis 30-days post-LT.
Methods: Patients who received a LT from Jan 2016-Dec 2017 were included in this single-site, retrospective review. Only patients with complete malnutrition data were analyzed. Patients were grouped according to nutrition inadequacy, with NI defined as meeting ≤75% of estimated energy needs (EEN) at post-operative day 7 (POD7). Those with NI were compared to patients meeting >75% EEN. Patient acuity was based on MELD, pre-LT dialysis, and ventilator dependence. Psoas muscle area (PMA) was obtained by CT/MRI scans at the L3 region within 6 months prior to LT and was a surrogate, objective marker of pre-LT malnutrition. Multivariable Cox regression analysis determined factors associated with sepsis within 30-days post-LT.
Results: Out of 233 LT recipients, only 109 met inclusion criteria and were analyzed. NI occurred in 62 (57%) patients. Nutritional support, either enteral or parenteral, was required in 58 (48%) patients. NI occurred more frequently in patients who did not receive nutritional support (54% vs 32%, p=0.01). Patients with NI had more pre-LT malnutrition indicated by smaller median (IQR) PMA: 7.5 cm^2 (5.8, 9.1) vs 8.3 cm^2 (5.8, 9.6), p=0.27. The NI group had *lower* acuity compared to the >75% EEN group: lower MELD scores, 20 (11, 32) vs 35 (22, 40), p<0.001; less pre-LT dialysis, n=8 (13%) vs n=25 (53%), p<0.001; and less ventilator dependence, n=9 (15%) vs n=21 (46%), p<0.001, respectively. Patients with NI had a significantly higher incidence of sepsis, n=12 (19%) vs n=2 (4%), p=0.02 (Figure 1). After adjustment, patients with NI were 5.14 times more likely to develop sepsis within 30-days of LT compared to those with >75% EEN (HR: 5.14, CI: 1.08, 24.43; p=0.04; Table1).
Conclusions: NI is an independent predictor of sepsis within 30 days of LT. Thus, perioperative nutritional status should be optimized for lower acuity patients who may not require nutritional support.



Characteristics associated with having sepsis within 30 days of liver transplant (C-statistic=0.73)		
Characteristics (N=109)	Adjusted HR (95% CI)	p-value
NI, nutritional inadequacy (energy at POD7)		
>75%	(reference)	
≤75%	5.14 (1.08, 24.43)	0.04
MELD	1.01 (0.96, 1.06)	0.68
Pre-transplant malnutrition (psoas muscle area)	1.07 (0.87, 1.32)	0.50
Donor age (years)	1.02 (0.98, 1.05)	0.36

Abstract# 342

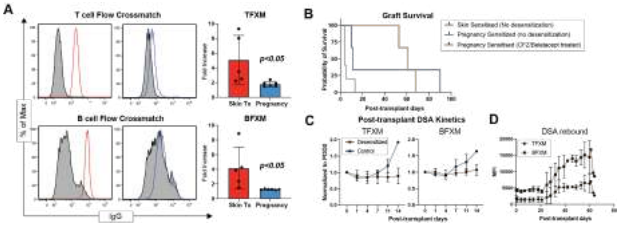
Natural Sensitization by Pregnancy, Testing Desensitization Strategies in Female NHPs Across Repeat Mismatches

M. Manook, J. Yoon, Z. Fitch, R. Schmitz, A. M. Jackson, J. Kwun, S. Knechtle, *Duke Transplant Center, Duke University Medical Center, Durham, NC*

Purpose: Women are disproportionately represented in the highly sensitized patient cohort, and HLA-incompatible transplantation is undertaken predominantly in females. However, nonhuman primate (NHP) models to date have relied on juvenile male animals. Therefore, we sought to examine the dual desensitization strategy using costimulation blockade and proteasome inhibition on naturally sensitized NHPs using multiparous female monkeys.

Methods: 6 multiparous animals were included in the study, 3 as controls, and 3 receiving desensitization. Donors were allocated following screening to ensure greatest flow crossmatch positivity, evidence of repeated mismatch based on offspring MAMU typing and maximal MAMU mismatching. Treated animals received desensitization with weekly carfilzomib (CFZ, 27mg/m^2) and belatacept (20mg/kg) for 4 weeks prior to kidney transplantation, followed by induction with rhesus ATG (RhATG), and maintenance with tacrolimus, mycophenolate mofetil and steroid. Comparison was made with skin sensitized control animals who did not receive desensitization n=5).

Results: Multiparous monkeys had a mean of 843±90.8 days between the last sensitizing event (pregnancy) and kidney transplantation. Compared to skin sensitized animals, naturally sensitized multiparous monkeys showed significantly lower donor-specific antibody (DSA) level on the day of kidney transplant **(Fig 1A)**. In accordance with this, multiparous female controls demonstrate heterogeneously prolonged survival, relative to animals sensitized directly to their donor by skin sensitization (**Fig 1B**). However, multiparous controls demonstrated early onset of DSA rebound compared to multiparous animals treated with carfilzomib and belatacept desensitization (**Fig 1C**). Desensitized multiparous animals showed better control of early post-transplant DSA, but DSA was significantly increased at post-operative day (POD) 42 compared to POD0 (BFXM MFI 13290 ±14 vs. 4477 ± 300, p = 0.016) (**Fig 1D**).



Conclusions: Real life pregnancy-induced MAMU sensitization results in rapid rise of DSA post-transplant, and reduced transplant survival suggesting an intact memory B cell compartment. Desensitization with CFZ and Belatacept prolongs survival, although control of post-transplant humoral response fails after 6 weeks on conventional triple immunosuppressive therapy.

Abstract# 343

AT-1501, a Novel and Clinically Applicable CD40L Specific Monoclonal Antibody, Promotes Islet Allograft Survival in Nonhuman Primates

D. Berman[1], N. Kenyon[1], M. Willman[1], A. Gill[2], S. Perrin[3], C. Ricordi[1], *[1]University of Miami, Miami, FL, [2]ALS Therapy Development Institute, Cambridge, MA, [3]Novus Therapeutics, Irvine, CA*

Purpose: Immune intervention with a CD40L specific monoclonal antibody (mAb, Hu5c8, Biogen) has previously been shown to safely and effectively prevent islet allograft (IA) rejection in three nonhuman primate (NHP) models. Clinical development for IA was precluded due to occurrence of thromboembolic complications (TE). AT-1501 (Novus Therapeutics) was engineered to preserve immune modulatory potential while avoiding TE and was shown to be safe in NHP. We tested AT-1501 in a diabetic cynomolgus monkey IA model, alone or in combination with additional agents.

Methods: A total of 5 groups (n=2 each, recipients MHC mismatched to the islet donor) received 10,000 or more IEQ/kg into the liver. An AT-1501 monotherapy group, with 25 mg/kg given IV on POD -1, 0, 3, 10, 18, 23 and 28 and every 14 days thereafter, was included to verify the previously observed efficacy of anti-CD40L. The other 4 groups incorporated T cell depletion with thymoglobulin (Thy; 5 peri-transplant doses at 5 mg/kg each), with a standard of care (SOC) group also receiving FK506 and rapamycin (target trough levels 8-12 and 4-6 ng/ml, respectively) plus Enbrel (0.8 mg/kg IV on POD 0 and 0.4 mg/kg SC on POD 3, 7, 10). For the remaining 3 groups, AT-1501 was given as described for monotherapy but with additional doses on POD -2, -1 and 7. One group involved immune suppression as for the SOC group but replacing FK506 with AT-1501.

Results: As compared to recipients in the SOC group, animals in the 4 AT-1501 treated groups had lower fasting blood glucose (FBG, 63 ± 14 vs 97 ± 19 mg/dl; p=0.04) and higher fasting (4.5 ± 0.1 vs 1.7 ± 0.1 ng/mg; p = 0.014) and stimulated (9.0 ± 2.1 vs 2.6 ± 0.4 ng/mg; p = 0.010) C-peptide/FBG. Animals in the AT-1501 groups experienced: greater weight gain, none to minimal CMV viral infection and down-regulation of anti-donor specific CD3/4 and 3/8 central memory T cells (at 2 months post-transplant). No class I or II alloantibody was observed.

Conclusions: AT-1501 appears to be a safe and effective agent to promote islet engraftment and long-term survival and a promising tool for tolerance induction strategies.

Abstract# 344

Interruption of Notch Signaling via Blockade of Delta-Like Ligand 4 Prevents Co-Stimulation Blockade Resistant Allograft Rejection

A. J. Matar, B. P. Lovasik, Y. Dong, D. A. Faber, J. Habib, C. Breeden, J. Regenold, A. Ghosh, A. Stephenson, W. H. Kitchens, A. B. Adams, *Emory University Department of Surgery, Atlanta, GA*

Purpose: Co-stimulation blockade (CoB) has emerged as a promising immunosuppression strategy with the advent of Belatacept, a novel CTLA4-Ig fusion protein that blocks CD28-mediated T cell co-stimulation. Compared to traditional calcineurin inhibitor-based immunosuppression, Belatacept confers improved graft survival, graft function, and overall survival in renal transplant recipients. However, it is also associated with increased rates of early acute rejection, termed CoB-resistant rejection (CoBRR). The purpose of this study was to examine the role of NOTCH pathway inhibition on CoBRR.

Methods: Murine and non-human primate (NHP) transplant models were used to investigate the role of NOTCH pathway inhibition via blockade of Delta-like ligand 4 (DLL4) on CoBRR.

Results: In a model of Balb/C to C57BL/6 skin transplantation, combined CoB (CTLA-4Ig + anti-CD154) and anti-DLL4 blockade significantly prolonged skin graft survival compared to CoB alone (MST 85 vs. 32 days, p = 0.001**). Anti-DLL4 blockade inhibited T cell activation and suppressed the formation of anti-donor antibody. Donor-specific T cell responses were also assessed in recipients of mOVA skin grafts following adoptive transfer of Thy1.1+ ovalbumin-specific OT-I T cells. Combined CTLA-4Ig and anti-DLL4 blockade suppressed donor-specific CD8+ T cell effector function via IFN-γ and TNF-α production. We then evaluated the effect of anti-DLL4 blockade in a NHP model of MHC mismatched renal transplantation. REGN421, a fully human IgG1 DLL4 monoclonal antibody, synergized with Belatacept to significantly prolong renal allograft survival compared to Belatacept alone (MST 151 vs. 38 days, p = 0.05*).

Conclusions: These data demonstrate that anti-DLL4 blockade is a promising therapy to suppress co-stimulation resistant alloreactivity and may help facilitate clinical translation of anti-DLL4 therapies in conjunction with Belatacept.

Abstract# 345

Belatacept and Carfilzomib-based Treatment of Active Antibody-mediated Rejection in a Sensitized Nonhuman Primate Model

J. Kwun[1], R. Schmitz[1], M. Manook[1], Z. Fitch[1], D. Olaso[1], A. Choi[1], J. Yoon[1], Y. Bae[1], J. Lambris[2], S. Knechtle[1], *[1]Surgery, Duke University, Durham, NC, [2]Pathology & Laboratory Medicine, University of Pennsylvania, Philadelphia, PA*

Purpose: One third of sensitized, HLA-incompatible transplant recipients experience antibody-mediated rejection (AMR) with limited effective treatment options. We tested a novel treatment strategy for AMR consisting of complement inhibition, proteasome inhibition and costimulation blockade in a nonhuman primate model.
Methods: Thirteen rhesus macaques were sensitized to maximally MHC mismatched donors by two sequential skin transplants. Primates subsequently received kidney allografts from their skin donors. All primates received induction therapy with rhesus-specific ATG (rhATG) and were maintained on different immunosuppressive regimens. Primates were monitored postoperatively for signs of AMR, which was defined as worsening kidney function resistant to high dose steroid rescue therapy, a rise in serum donor-specific antibody (DSA) levels, and biopsy evidence of active AMR. AMR treatment consisted of carfilzomib and belatacept for a maximum of 4 weeks.
Results: Treatment with carfilzomib and belatacept was well tolerated and we did not observe any treatment-specific side effects. Once AMR developed, animals without further treatment rejected their graft rapidly. However, animals treated with carfilzomib and belatacept showed prolonged graft survival after the AMR treatment compared to control animals (5d vs. 28.5d, $p < 0.01$; **Figure 1A**). As shown in **figure 1B**, animals without treatment showed significant elevation of serum creatinine (sCr) while profound reduction of sCr was observed in treated animals. After initiation of treatment, we observed a significant reduction of both class I and class II DSA (**Figure 1C**). However, all animals showed rebound of DSA when the treatment was discontinued.
Conclusions: Carfilzomib and belatacept were able to control on-going humoral immune response seen during AMR in a nonhuman primate model. This was associated with improved graft function and prolongation of graft survival. Further studies in optimizing maintenance immunosuppression after carfilzomib and belatacept treatment is warranted to continuously control post-transplant humoral response in the sensitized recipients.

Pierson III[1], *[1]Surgery, Center for Transplantation Sciences, Massachusetts General Hospital, Boston, MA, [2]Surgery, University of Maryland, Baltimore, MD, [3]Revivicor, Blacksburg, VA*

Purpose: Novel gene editing techniques have facilitated the generation of donor pigs with multiple genetic modifications, used for xenolung transplantation. Several rejection pathways, including antibody binding, complement and coagulation activation, have been identified, leading to inflammation with cytokine release. Here we tested in a rigorous lung transplantation model whether Alpha 1-Antitrypsin (A1AT) treatment reduces cytokine release and improves survival.
Methods: GalTKO.hCD46 porcine lungs, additionally expressing hEPCR or hEPCR.hCD47.hTFPI.hCD55 or hEPCR.hTBM/others were used in 17 single lung transplants into baboons. In 11 further transplantations, recipients were additionally treated with A1AT. All recipients received a "platform drug regimen" including steroids, sC1Inh, thromboxane synthase inhibition, anti-histamine, and αGPIb Fab. Immunosuppression consisted of αCD20, ATG, MMF, αCD40. Donors were treated with Desmopressin to deplete pig endothelial vWF. Quantification of cytokines was done by Luminex assay, using baboon plasma, collected at baseline, 4, 12 and 24 hours after reperfusion.
Results: A1AT treatment was associated with reduced elaboration of IL6, IL8, and IFN-γ for all tested pig genetic cohorts (Fig.1 A, B, D). TNF-α showed lower values in the hEPCR and hEPCR.hCD47.hTFPI.hCD55 groups but not with hEPCR.hTBM lungs at the 4h time point (Fig.1 C). A1AT was also associated with longer recipient survival, including the two longest survivors in the hEPCR.hTBM group (7 and 9 days) in this analysis.
Conclusions: The results of this study demonstrate that xenogeneic lung transplantation leads to a significant inflammatory response with high cytokine release. Within the analyzed lung phenotypes, A1AT treatment was associated with a trend toward attenuated cytokine elaboration and prolonged recipient survival, suggesting that A1AT attenuates proinflammatory pathways critical to xenografts injury. Further mechanism-directed transgenic modifications and drug treatments may facilitate clinical translation.

Abstract# 347

Pig Orthotopic Heart Transplantation (ohtx) in Baboons: Is an Acute Pulmonary Inflammatory Response the Key Problem?

A. Jagdale[1], D. Cleveland[2], M. Bikhet[1], J. Foote[3], G. Walcott[4], H. Iwase[1], T. Yamamoto[1], H. Hara[1], C. Hansens-Estruch[1], D. Ayares[5], S. Litovsky[6], L. Rhodes[2], W. Carlo[7], J. Crawford[2], R. Dabal[2], S. Borasino[2], D. Cooper[1], *[1]Surgery, University of Alabama at Birmingham, Birmingham, AL, [2]Cardiothoracic Surgery, Children's of Alabama, Birmingham, AL, [3]Medicine and Cardiovascular Diseases, University of Alabama at Birmingham, Birmingham, AL, [4]Medicine, University of Alabama at Birmingham, Birmingham, AL, [5]Surgery, Revivicor, Blacksburg, VA, [6]Pathology, University of Alabama at Birmingham, Birmingham, AL, [7]Division of Pediatric Cardiology, Department of Pediatrics, University of Alabama at Birmingham, Children's of Alabama, Birmingham, AL*

Purpose: To investigate the mechanism of early cardio-pulmonary dysfunction after genetically engineered pig OHTx in baboons.

Methods: OHTx from pigs expressing different genetic modifications, α-galactosyltransferase knockout with human CD55 (GTKO/hCD55) [n=2]; α-galactosyltransferase knockout with human CD46 and human thrombomodulin (GTKO/hCD46/hTBM) [n=2] was carried out in 4 baboons. The immunosuppressive regimen included induction with ATG (Thymoglobulin), anti-CD20mAb (Rituximab), and cobra venom factor or a C1-esterase inhibitor, and maintenance with an anti-CD40mAb, rapamycin, and low-dose steroids.

Results: Four baboons (<12 kg) underwent orthotopic cardiac transplant of a genetically engineered pig xenograft. All four successfully emerged from cardio-pulmonary bypass. Two baboons were euthanized a few hours after OHTx while the other 2 baboons survived 3 and 8 months, respectively. Features of pulmonary dysfunction in the early post-operative period (e.g., tachypnea, reduced pO_2, reduced sO_2 etc.), particularly in the 24 hours following weaning from the ventilator, developed in all 4 baboons. The 2 baboons that were euthanized showed very high levels of IL-6, IL-8, and IFN-γ compared to the 2 that survived longer, suggesting a possible association between cytokine storm and acute pulmonary injury. Histopathological examination confirmed inflammatory lung injury in 3 baboons, including the 3-month survivor (that died from a dysrhythmia).

Conclusions: After pig OHTx in baboons, all of our baboons experienced acute pulmonary dysfunction. Because pulmonary dysfunction can lead to impaired cardiac graft function, further research is indicated regarding the role of cytokine storm in acute pulmonary dysfunction particularly since treatment with IL-6 blockade or dexamethsone can attenuate this cytokine response.

Abstract# 348

Successful Long-Term TMA- and Rejection-Free Survival of a Kidney Xenograft With Triple Xenoantigen Knockout Plus Insertion of Multiple Human Transgenes

T. Hirose[1], D. Ma[1], G. Lassiter[1], H. Sasaki[1], I. Rosales[2], T. Coe[1], C. Rickert[1], R. Matheson[1], R. Colvin[2], W. Qin[3], Y. Kan[3], J. Layer[3], K. Stiede[3], K. Hall[3], M. Youd[3], W. Westlin[3], M. Curtis[3], J. F. Markmann[1], T. Kawai[1], *[1]Center for Transplantation Sciences, Massachusetts General Hospital, Boston, MA, [2]Pathology, Massachusetts General Hospital, Boston, MA, [3]eGenesis Inc, Cambridge, MA*

Purpose: Pigs with deletion of 3 carbohydrate xenoantigens (triple knock-out, TKO) are expected to be optimal donors for human xenotransplantation. However, anti-porcine natural antibodies of old world monkeys (OWM), such as baboons, cynomolgus or rhesus monkeys, have been shown to have higher bindings to TKO cells with rapid rejection of the renal xenografts in baboons. Therefore, it is crucial to establish a preclinical model that can reliably evaluate xenografts from TKO pigs. Here, we show, for the first time, the long-term TMA- and rejection- free renal xenograft survival from TKO pigs can be achieved using cynomolgus macaques.

Methods: Eight cynomolgus monkeys received kidneys from two different TKO pigs lines with human complement, inflammation, and immune regulatory transgenes (TKO-A, TKO-B). The expression of transgenic human complement related genes (CD46, CD55 and CD59) was low on TKO-A, but high on TKO-B. The recipients were treated with ATG and anti-CD20 mAb as an induction, followed by weekly anti-CD154 mAb, daily MMF with or without 1-2 months course of rapamycin or tacrolimus. The levels of pre-transplant recipient IgG/IgM antibodies against donor porcine endothelial cells were measured by flow cytometry.

Results: Anti-TKO IgG levels of all recipients were comparable to those of pooled human serum except for one recipient (TKO-A2), while anti-TKO IgM levels were consistently higher than those of pooled human serum (Fig. 1). TKO-A1 rejected xenograft rapidly on day 2, while TKO-A2 survived for 61 days, despite high anti-pig IgG and IgM titers. Among 6 recipients of TKO-B, although 2 monkeys (TKO-B1 and 2) rejected with TMA within 3 weeks (15 and 20 days) , 4 recipients (TKO-B3 to 6) achieved long-term survival (71, 135, 265 and 316 days) (Fig. 2). In the 3/4 long-term survivors, rejection or TMA was observed only after reduction of immunosuppression due to infectious complications, leading to rejection and TMA free xenograft survival reached up to 237 days. In this study, there was no significant correlation found between pre-transplant anti-TKO IgG and IgM levels and the transplant outcome.

Conclusions: TKO with multiple human transgenes allowed kidney graft survival up to 316 days with TMA- and rejection-free xenograft survival up to 237 days.

Abstract# 349

Impact of Allosensitization on Xenotransplantation

D. Olaso[1], M. Manook[1], J. Yoon[1], Y. Bae[1], A. Barbas[1], A. Adams[2], S. Knechtle[1], J. Kwun[1], *[1]Department of Surgery, Duke Transplantation Center, Durham, NC, [2]Department of Surgery, University of Minnesota, Minneapolis, MN*

Purpose: Sensitization to human leukocyte antigens (HLA) due to prior exposure to foreign antigens through events such as blood transfusions, previous kidney transplant, or pregnancy is associated with worse post-transplant graft survival and

increased risk of graft loss due to antibody-mediated rejection (AMR). We sought to explore xenotransplantation in the highly sensitized recipient to characterize how allosensitization impacts immunologic rejection after xeno-kidney transplant.
Methods: Four nonhuman primates (NHP) were allosensitized with maximally HLA-mismatched rhesus donor skin grafts. Six to eight weeks after the second skin graft, porcine kidneys from genetically modified knockout a-1,3-galactosyltransferase (GGTA1KO) and human decay accelerating factor transgenic (CD55Tg) pigs were transplanted into the allosensitized NHPs. The immunosuppression regimen consisted of rhesus anti-CD4 and anti-CD8 induction, and anti-CD154 mAb (rh5C8), mycophenolate mofetil, and corticosteroids as maintenance therapy. Both xeno-reactive and allo-specific antibodies were evaluated with flow crossmatch.
Results: All animals tolerated xeno-kidney transplantation well with no cases of hyperacute rejection. NHPs received pulsed corticosteroid per rejection protocol but no rejections reversed. All four animals rejected their grafts at POD 12, 15, 27, and 55 (MST = 27.25d). Xeno-graft survival was greatly prolonged compared to highly sensitized animals with allo-kidney transplants without desensitization (MST=7d). However, compared to previously reported non-sensitized recipients with xeno-kidney transplantation (MST=201.8d), graft survival was significantly reduced by allosensitization (**Figure 1A and 1B**). Interestingly, flow crossmatch revealed elevated xeno-DSA that coincided with rejection (**Figure 1C**), and allosensitization was not boosted by rejection of a xenograft.
Conclusions: This is the first attempt, to our knowledge, to perform xenotransplantation in highly allosensitized NHP recipients. Allosensitization leads to overall decreased xeno-graft survival and increased risk of graft loss due to AMR compared to non-sensitized recipients. Further studies in optimizing desensitization and maintenance immunosuppression therapies are warranted to further characterize the clinical utility of xenotransplantation in the allosensitized recipient.

Basic

Ischemia Reperfusion & Organ Rehabilitation

Abstract# 350
Beneficial Effects of Argon Inhalation on Reducing Lung Ischemia-reperfusion Injury in Miniature Swine
H. Sahara, *Div. Organ Replacement and Xeno Tx, Center for Advanced Biomedical Science and Swine Research, Kagoshima University, Kagoshima, Japan*
Purpose: Noble gases, such as xenon and argon (Ar), are chemically inert but have shown to have cytoprotective effect. In contrast to xenon, Ar is the non-anesthetic and the third most abundant gas in the earth's atmosphere suggesting its higher safety level and economic benefit. The effects of Ar on reducing ischemia-reperfusion injury (IRI) have been reported in a variety of organs in murine models, however, the results from large animal models have been still controversial. In this study, we evaluated the cytoprotective effects of Ar inhalation in in situ porcine lung model of 90-minutes warm IRI.
Methods: Ten CLAWN miniature swine were evenly divided into two groups (Ar-treated and control group). In both groups, warm ischemia was induced for 90 minutes by clamping the left bronchus, pulmonary artery and veins. Animals were inhaled with either 70% Ar (Ar-treated) or 70% nitrogen (control) in 30% oxygen for 360 minutes throughout the procedure. Lung function and structure were serially assessed via the ratio of partial pressure of oxygen to fractional inspired oxygen (pO_2/FiO_2) measured by both arterial blood and pulmonary vein (PV), chest X-ray and lung biopsy.
Results: Ar inhalation dramatically decreased lung injury associated with ischemia and reperfusion without apparent adverse effects. In the control group, 90 minutes of warm ischemia resulted in a significant decrease in pO_2/FiO_2 by arterial blood, from 568 +/-12 mmHg before ischemia to 272 +/-39 mmHg 2 hours after reperfusion ($p<0.05$). In sharp contrast, animals in the Ar-treated group had no significant change in pO_2/FiO_2 by arterial blood despite 90-min ischemia (563 +/-18 mmHg before ischemia to 431 +/-49 mmHg 2 hours after reperfusion). Moreover, pO_2/FiO_2 by PV showed well-maintained lung function in the Ar-treated group (331 +/-40 vs. 186 +/-17 at 2 hours, $p<0.05$; 519 +/-19 vs. 292 +/-33 at 2 days after reperfusion, $p<0.05$). Histologic scores of lung biopsy specimens based on light microscopy which was calculated on the basis of the evaluation of cell infiltration, intra-alveolar edema, fibrin exudation and hemorrhage showed significantly better in the Ar-treated group at both 2 hours and 2 days after reperfusion.
Conclusions: To our knowledge, this is the first demonstration of the beneficial effects of perioperative inhalation of Ar on IRI of the lung in a large animal model. Further studies are required to clarify the exact mechanism of the effect of Ar inhalation including anti-inflammation, anti-apoptotic or anti-oxidation for clinical application of this novel therapy.

Abstract# 351
Eosinophils Attenuate Hepatic Ischemia Reperfusion Injury in Mice Through St2-Dependent Il-13 Production
Y. Yang, Y. Wang, M. Wang, J. Jeong, L. Xu, Y. Wen, C. Emontzpohl, W. Dar, C. Ju, *Department of Anesthesiology, McGovern Medical School University of Texas Health Science Center at Houston, Houston, TX*
Purpose: The purpose is to investigate the functional role of eosinophils during hepatic ischemia and reperfusion injury (IRI).
Methods: Mice with antibody-induced eosinophil depletion and two strains of mice with genetic deletion of eosinophils were be used in the studies.
Results: Unexpectedly, we identified a rapid accumulation of eosinophils in human liver grafts following hepatic transplantation. In contrast, no eosinophils were detectable in healthy liver tissues. Studies with genetic models of eosinophil deficiency or antibody-mediated eosinophil depletion revealed exacerbated injury following hepatic ischemia and reperfusion. Adoptive transfer of bone marrow-derived eosinophils normalized liver injury of eosinophil-deficient mice and reduced hepatic ischemia and reperfusion injury in wild-type mice. Mechanistic studies combining genetic and adoptive transfer approaches identified a critical role of suppression of tumorigenicity (ST2)-dependent production of interleukin-13 by eosinophils in the hepatoprotection against ischemia reperfusion-induced injury.
Conclusions: Taken together, the present studies uncovered a previously unrecognized hepatoprotective function of eosinophils and implicated the IL-33/ST2-dependent IL-13 production in mediating the protective effect. The findings support further exploration of eosinophils and IL-33/ST2 signaling as candidate therapeutic targets to improve the outcomes of liver surgery and transplantation.

Abstract# 352
Neutrophil Extracellular Trap-induced Thrombotic Microangiopathy in Steatotic Mouse Recipients Impacts Liver Transplant Outcomes
H. Hirao, H. Kojima, K. Kadono, K. J. Dery, D. G. Farmer, F. M. Kaldas, J. W. Kupiec-Weglinski, *UCLA Medical Center, Los Angeles, CA*
Purpose: Nonalcoholic steatohepatitis (NASH) is an emerging global epidemic projected to become the leading indication for liver transplantation (LT). Although recent studies focus on the utilization of steatotic livers as marginal grafts, little is known as to whether and how the recipient steatosis may affect LT outcomes. It was shown that mice with severe hepatic steatosis were highly susceptible to neutrophil

extracellular trap-related cell death (NETosis) and subsequent thrombosis formation. The present study was aimed to assess whether the severity of steatosis in prospective mouse recipients may influence the course of donor LT.
Methods: Four-week old WT mice (C57/BL6) were fed with normal diet (ND) or high fat diet (HFD) for 4 or 12 weeks. Four-week HFD feeding resulted in the development of microvesicular steatosis (<30% lipid droplet), while 12 week HFD feeding led to classic macrovesicular steatosis (>60%). Donor WT livers were then transplanted, after cold storage (4oC/90min), to distinct groups of syngeneic: 1/ ND-WT, 2/ HFD (4w)-WT or 3/ HFD (12W)-WT recipients. LTs samples collected at 6h and 24h were analyzed by qRT-PCR, western blotting and immunohistochemistry.
Results: Mouse recipients in HFD (12w) group had significantly higher post-LT transaminase release/enhanced pro-inflammatory cytokine/chemokine profiles at 6h post-LT, as compared to ND or HFD (4w) groups. Unexpectedly, HFD (12w)-fed recipients failed to survive longer than 2 days post-LT, despite all recipients surviving >14days in ND and HFD (4w)-fed groups. Western blot analysis revealed that the expression of LC3B (autophagy marker) was significantly impaired, while VCAM-1 and CD62P (endothelial damage markers) were significantly upregulated in HFD (12w) group at 24h post-LT. Immunohistochemistry analysis of CD42b, Ly6G, and Histone H3 expression/levels showed NET related platelet thrombosis was profoundly augmented in HFD (12w)-fed recipients. These results indicate that mouse recipients suffering from severe steatosis prior to liver transplantation were highly susceptible to LT-related hepatic IR-stress/injury.
Conclusions: This study documents that severely steatotic mouse recipients even when transplanted with healthy donor livers may experience NETosis-related thrombosis, accompanied by poor post-LT outcomes.

Abstract# 353

Single Cell Analysis of Living Donor Kidneys Reveals Sex-based Diversity in Proximal Tubulargene Expression

C. M. McEvoy[1], J. M. Szusz[2], S. Clotet-Freixas[1], J. An[2], S. MacParland[2], G. Bader[3], S. Q. Crome[2], A. Konvalinka[1], *[1]Ajmera Transplant Centre, Toronto General Hospital Research Institute, Toronto, ON, Canada, [2]Immunology and Molecular Genetics, University of Toronto, Toronto General Hospital Research Institute, Toronto, ON, Canada, [3]Donnolly Centre for Cellular and Biomolecular Research, University of Toronto, Toronto, ON, Canada*
Purpose: Males with chronic kidney disease (CKD) experience a more rapid decline in kidney function and progression to end-stage kidney disease than females. *In vitro* studies further support a sexually dimorphic response to kidney injury. The molecular basis for the poor prognosis associated with male sex in CKD remains unclear. Single-cell RNA sequencing enables precise characterization of the transcriptional signature from individual cells. Such sex-specific single cell transcriptional profiles would transform our understanding of the impact of sex on CKD progression.
Methods: We sequenced single-cell suspensions of 19 pre-implantation kidney biopsies from 9 male and 10 female living kidney donors (10X Genomics). 10 biopsies (5 male, 5 female) underwent CD45+ selection to enhance representation of immune cell populations. Mapping and quantification were performed using the Cellranger software package. Ambient RNA contamination was corrected using SoupX, and doublets removed using DoubletFinder. Normalization and clustering were performed using the Seurat pipeline. Sex-based transcriptional differences were identified using varimax rotational analysis.
Results: All expected parenchymal populations from both glomerular and tubulointerstitial compartments featured on our map (Fig1A). Striking sex-specific differences in gene expression were identified in proximal tubular (PT) cells, which contributed ~80% of all cells in these healthy kidneys (Fig1B). Interestingly, X/Y-chromosome encoded genes and phenotypic genes (e.g. LRP2) were among these sex-specific genes altered in PT cells. Genes with higher expression in females were associated with important metabolic processes including detoxification, antioxidant processes and the negative regulation of cell death. In contrast, processes related to nonsense mediated decay and the cellular response to stress were enhanced in males.
Conclusions: We have generated a comprehensive healthy kidney map with novel focus on sex-specific differences in kidney cell populations. Male and female PT epithelial cells display marked changes in genes associated with metabolism and antioxidant activities. These changes might underpin the differences in male and female susceptibility to CKD.

Abstract# 354

Hepatocyte SIRT1 Suppresses Atf4-mediated Apoptosis Triggered by Cold Stress in Mouse and Human Liver Transplantation

K. Kadono[1], H. Hirao[1], H. Kojima[1], K. J. Dery[1], J. Aziz[1], X. Li[2], J. W. Kupiec-Weglinski[1], *[1]Dumont-UCLA Transplant Center, Los Angeles, CA, [2]NIEHS, Durham, NC*
Purpose: The role of ER-stress or hepatocyte-specific SIRT1 signaling during donor liver cold preservation remains unknown. We employed a mouse OLT model and analyzed clinical liver transplant biopsies (Bx) to determine as to whether and how hepatocyte SIRT1- ER stress (p-eIF2α/ATF4)-apoptosis axis may affect outcomes.
Methods: WT or hepatocyte-specific SIRT1 deficient (hSIRT1-KO) livers (C57/BL6), subjected to extended (18h) cold storage (4C in UW solution), were transplanted to syngeneic WT recipients. Liver/serum samples were collected at 6h post-reperfusion. Human liver Bx collected from 60 OLT patients (after cold storage and 2 hrs after reperfusion) were analyzed by Western blots/RT-PCR.
Results: hSIRT1-KO primary hepatocytes showed increased levels of ATF4 and up-regulation of PUMA/BAX/Cleaved Caspase-9 while levels of p-eIF2α/CHOP remained unchanged as compared to WT counterparts (Figure 1). Furthermore, silencing (siRNA) of ATF4 reduced levels of PUMA/BAX but not of CHOP in hepatocyte cultures. Compared with WT liver grafts (WT>WT), disruption of hepatocyte SIRT1 signaling in the donor liver (hSIRT1-KO>WT) aggravated IRI, as evidenced by: 1/ sALT/sAST levels (ALT: 7321±6104 vs 3875±1869 IU/L, n=12/12, p=0.037; AST: 3671±2678 vs 1853±532 IU/L, n=12/12, p=0.015); 2/ Suzuki's histological grading ($p<0.05$); 3/ frequency of TUNEL+ cells ($p<0.05$); 4/ augmented neutrophil/macrophage infiltration (IHC, $p<0.05$); 5/ increased hepatic ATF4/PUMA/Cleaved Caspase-9/Cleaved Caspase-3 expressions (WB, $p<0.05$); and 6/ impaired survival of IR-stressed OLTs (2-weeks: 11% vs 44%, n=9/9, p=0.036). Cold-stored liver grafts showed up-regulation of p-eIF2α/ATF4 and PUMA/Cleaved Caspase-9 while CHOP levels decreased (Figure 2). Consistently, cold-stressed hepatocytes displayed increased levels of p-eIF2α/ATF4 and PUMA/BAX/Cleaved Caspase-9, with CHOP relatively unchanged (Figure 3). In the clinical arm, pre-reperfusion SIRT1 levels in human liver Bx negatively correlated with protein expression levels of ATF4 (r=-0.313, p=0.056) but positively with Bcl-2 (r=0.4519, p=0.0003), while post-reperfusion hepatic SIRT levels in OLTs negatively correlated with ATF4 (r=-0.2684, p=0.0058) and Cleaved Caspase-3 (r=-0.4213, p=0.0111).
Conclusions: This translational study documents hepatocyte SIRT1 regulates ATF4 mediated apoptosis triggered by cold-stress, providing a novel therapeutic target and putative mechanism of hepatocyte-specific cell death pathway.

Abstract# 355

Estrogen Receptor Beta Deletion is Protective in Renal Ischemia Reperfusion Injury in a Renal Specific Manner

C. S. O'Brien, P. Hernandez, Z. Wang, G. Ge, W. Hancock, M. H. Levine, *Surgery, University of Pennsylvania, Philadelphia, PA*

Purpose: Renal Ischemia Reperfusion Injury (IRI) is a major contributor to delayed graft function (DGF) in kidney transplantation. Previously, we have shown lower rates of DGF among female renal transplant recipients in the UNOS registry, and using a murine model, we demonstrated improved IRI tolerance with administration of supplemental 17β-estradiol (E2) and selective estrogen receptor modulators (SERM). There are two principal estrogen receptors, estrogen receptor alpha (ERα) and estrogen receptor beta (ERβ), and expression varies by tissue type. We have shown decreased ischemia tolerance in ERα knockout mice (ERα-KO). Given the therapeutic potential of manipulating the estrogen receptors with E2 or SERM, understanding the role of the ERβ in renal IRI is essential.

Methods: Female Erβ-KO mice and ERαβ-KO mice underwent warm renal ischemia along with B6 controls. Renal ischemia was repeated with ERαβ-KO and ERα-KO mice using a shortened ischemic time. Additionally, we transplanted kidneys from C57BL/6(B6) donor mice into B6 recipient mice, ERβKO kidneys into B6 recipients, and B6 kidneys into ERβKO recipients, followed by native nephrectomy. All groups subsequently underwent standardized renal IRI. Blood urea nitrogen (BUN) and serum creatinine (Cr) were measured at 24-, 48-, 72- and 96-hours after IRI.
Results: ERβ-KO mice had significantly lower BUN and Cr compared to B6 mice ($p<0.001$, Figure 1a). 5 of 7 ERαβ-KO mice undergoing standard IRI experienced fatal renal injury, as compared to zero controls, with ERαβ-KO mice having significantly higher BUN (135 +/-14) than B6 controls (104 +/-13, $p=0.003$) at 24 hours. In modified IRI, ERαβ-KO had no difference from ERα-KO mice (Figure 1b). ERβ-KO mice that received B6 kidneys (B6=>ERβKO) had significantly higher BUN and Cr compared to B6 mice that received ERβKO kidneys (ErβKO=>B6) ($p<0.001$) and significantly higher Cr than B6 mice that received B6 kidneys (B6=>B6) ($p<0.05$, Figure 1c).
Conclusions: ERβ-KO is protective against renal IRI, but combined deletion of ERα and ERβ recapitulates the previously shown harmful effects of ERα deletion. The protective effect of ERβ deletion appears to be localized to the kidney. Differential blockade of ERα and Erβ in the kidneys vs. the periphery may provide an avenue to increase the protective effects of estrogen in renal IRI.

Abstract# 356

Cellular Landscape of Steatotic Livers Revealed by Single-nuclei Rna Sequencing

C. Kuscu[1], C. Kuscu[1], A. Shetty[2], E. Bardhi[3], T. Rousselle[4], J. Eason[1], M. Sraj[5], D. Maluf[6], V. Mas[4], *[1]Surgery, James D Eason Transplant Institute, Memphis, TN, [2]University of Maryland, Institute for Genome Sciences, Baltimore, MD, [3]Program in Transplantation - University of Maryland, Baltimore, MD, [4]Surgery, Division of Surgical Science, Baltimore, MD, [5]Surgery, University of Maryland, Baltimore, MD, [6]Surgery, Program in Transplantation - University of Maryland, Baltimore, MD*

Purpose: Hepatic IRI represents a barrier to the use of available organs for transplant, particularly fatty livers. We aimed to discern the cellular subsets and individual transcriptomics that characterize human steatotic livers
Methods: Single nuclei were isolated from normal (NL) and fatty (FL) (30% macrosteatosis) liver samples (n=4). Liver tissues were matched by age, sex, and gender. > 30,000 nuclei in Gel-Bead V3 were captured by using the droplet-based 10X Genomic Chromium Platform. Data was analyzed in CellRanger 3.1.0. Cell clustering using PCA followed by uniform manifold approximation and projection (UMAP) was done. Distinct clusters of cells based on GE of highly variable genes were identified. GE patterns between clusters were evaluated to find cluster-specific marker genes.
Results: A total of 18 cell clusters were identified from the integration of total nuclei gene markers, which resulted in 13 cell clusters based on gene markers (representation of parenchymal and non-parenchymal liver cells) (**Fig. 1**). Normal to fatty liver comparisons were done and main observations included the identification of two hepatocyte cell subsets, Hep1 and Hep2; with Hep2 cells present predominantly in FL (Hep 2, NL= 87 *vs.* FL= 2390) and a significant decreased number of hepatic stellate cells (HSCs) in FL (NL= 345 vs. FL= 28) and endothelial cells (ECs) (N= 1122 *vs.* FL= 625) in FL. Analyses of DEGs between FL and NL Hep1 cells showed a lower expression of genes related to complement and coagulation components *(CD46, CD55, C8, SERPINA1, fibrin, PLG, KNG1, KLKB1, KNG1*) in FL Hep1. Hep2 cells were characterized by increased expression of genes related to acute phase response signaling, oxidation of lipids, FGF21 signaling, angiogenesis and development of vasculature. HSCs in FL presented an activated phenotype (while a quiescent HSC phenotype was observed in NL HSCs).
Conclusions: These results support the use of single liver cell transcriptomics as a tool to identify specific cells/pathways that may represent targets for IRI therapeutic intervention for expanding the use of fatty liver organs

Abstract# 357

Cross-Circulation for Extracorporeal Liver Support in a Swine Model

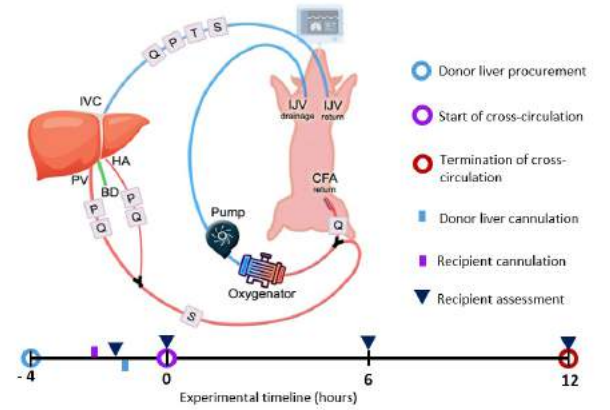
W. K. Wu[1], A. Tumen[1], J. W. Stokes[2], R. Ukita[2], A. E. Hozain[3], C. R. Flynn[2], M. J. Lee[3], J. R. Talackine[2], N. L. Cardwell[2], J. A. Reimer[3], M. Pinezich[3], C. Benson[2], G. Vunjak-Novakovic[3], S. P. Alexopoulos[2], M. Bacchetta[2], *[1]co-first authors, Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Columbia University Medical Center, New York, NY*

Purpose: Although machine perfusion has gained momentum as an organ preservation strategy in liver transplantation, significant organ shortages and waitlist mortality persist, highlighting unmet needs for improved organ salvage. We present a clinically relevant, large animal model of extracorporeal liver support using cross-circulation (XC).

Methods: Livers (n = 4) were procured from donor swine and placed on normothermic veno-arterial-venous (V-AV) XC with swine hosts for 12 hours (**Figure 1**). Longitudinal analyses of the extracorporeal livers (functional assessments, multiscale morphology, injury markers) and host swine (vital signs, blood, and tissue analyses) were performed at 0, 6, and 12 hours following initiation of XC.

Results: Throughout 12 hours of normothermic support, extracorporeal livers demonstrated stable oxygen consumption, lactate clearance, bile production, and alkaline bile composition. (**Figure 2A-D**). There was no significant biochemical or histological evidence of hepatocellular injury (**Figure 2E-K**). Circuit parameters remained physiologic (hepatic artery flow 0.33 ± 0.03 L/min, portal venous flow 0.75 ± 0.03 L/min, hepatic venous pressure gradient 6.8 ± 2.4 mmHg), and recipient swine remained hemodynamically stable.

Conclusions: We demonstrate the feasibility of physiologic extracorporeal liver support using V-AV XC in a swine model. XC has potential application as a translational research platform and as clinical biotechnology for donor organ salvage and recovery.



BD: bile duct. CFA: common femoral artery. HA: hepatic artery. IJV: internal jugular vein. IVC: inferior vena cava. P: pressure transducer. PV: portal vein. Q: flow probe. S: oxygen saturation probe. T: temperature probe.

Hepatitis C

Abstract# 358

Association of Donor Hepatitis C Virus Infection Status and Risk of Bk Polyomavirus Viremia After Kidney Transplantation

V. S. Potluri[1], D. E. Schaubel[1], M. E. Sise[2], B. P. Concepcion[3], R. C. Forbes[1], E. A. Blumberg[1], D. Goldberg[4], P. P. Reese[1], R. Bloom[1], D. Shaffer[3], R. Chung[2], D. Sawinski[1], I. Strohben[2], N. Elias[2], A. Azhar[5], M. Shah[1], J. Eason[5], L. A. Binari[3], M. Talwar[5], V. Balaraman[5], A. Bhalla[5], B. Besharatian[1], M. Z. Molnar[5], *[1]University of Pennsylvania, Philadelphia, PA, [2]Massachusetts General Hospital, Boston, MA, [3]Vanderbilt University Medical Center, Nashville, TN, [4]University of Miami Miller School of Medicine, Miami, FL, [5]Methodist University Hospital, Memphis, TN*

Purpose: Transplantation of kidneys from deceased donors with hepatitis C virus (HCV) infection into HCV-negative recipients has become more common, but some studies have suggested elevated risks of immunological complications such as BK polyomavirus (BKPV). Prior studies have generally been limited by single-center populations, low granularity data and/or no comparator group.

Methods: We assembled a retrospective cohort of adult HCV-negative recipients of HCV-viremic kidneys and recipients of HCV-aviremic kidneys receiving care at four centers (COAUTHOR consortium: UPenn, MGH, Vanderbilt, Methodist Hospital) with regular screening for BKPV infection. We used optimal matching with variable number of controls, where each HCV-viremic kidney recipient could be matched to at least one and a maximum of five comparators. Recipients were matched on risk factors for BKPV viremia, including induction therapy, as well as allocation KDPI. The primary outcome was BKPV viremia ≥ 1,000 copies/mL or biopsy-proven BKPV nephropathy in the first post-transplant year. Outcomes were analyzed using Cox regression, weighted and stratified by matched set and expressed per 100 patient-years (PY).

Results: The final matched cohort comprised 146 recipients of HCV-viremic kidneys and 453 matched comparators. HCV-viremic kidney transplantation was not associated with an elevated risk of BKPV viremia ≥ 1,000 copies/mL. HCV-viremic kidney transplantation had a non-significant association with the outcome of BKPV viremia ≥ 10,000 copies/mL; many of these infections took place at a center with delayed initiation of direct acting antiviral therapy. No biopsy proven BKPV nephropathy was observed. One year eGFR was clinically similar between groups. Only one HCV-viremic kidney transplant recipient had primary graft loss.

Incidence of BKPV Viremia					
BK >1,000 copies/mL	BKPV Viremia events	Patient-years of follow-up	Rate per 100 PY	Weighted Rate per 100 PY	Hazard Ratio (95% CI)
Donor HCV NAT-	68	381.9	17.8	22.2	1 (ref)
Donor HCV NAT+	33	125.8	26.2	26.2	1.15 (0.82, 1.61) p=0.42
Total	101	507.7	19.9	-	N/A
BK >10,000 copies/mL					
Donor HCV NAT-	41	396.8	10.3	13.3	1 (ref)
Donor HCV NAT+	25	128.6	19.4	19.4	1.48 (0.97, 2.24) p=0.07
Total	66	526.4	12.5	-	N/A

Conclusions: HCV-viremic kidney transplantation was not associated with an elevated risk of BKPV viremia. While the data suggested the possibility that donor HCV conferred a higher risk of BKPV viremia ≥ 10,000 copies/mL associated with HCV, one year graft function outcomes for HCV-viremic recipients were reassuring.

Abstract# 359

Outcomes of Short-Duration Anti-Viral Prophylaxis for Hepatitis C Positive Donor Kidney Transplants

G. Gupta, I. Yakubu, P. Kimball, L. Kang, K. Mitchell, M. Shinbashi, D. Kumar, I. Moinuddin, L. Kamal, A. King, C. Bhati, M. Levy, A. Cotterell, A. Sharma, R. Sterling, *Virginia Commonwealth University Health System, Richmond, VA*

Purpose: Trials describing 4-12 week courses of direct-acting anti-viral drugs (DAAs) to treat hepatitis C virus (HCV) transmission from infected donors to uninfected kidney transplant recipients (D+/R- transplants), may be limited in application to the 'real-world' by costs and delayed access to expensive DAAs. We previously reported HCV transmission of 12% among D+/R- transplants (N=52) with 2-4 day pangenotypic sofosbuvir/velpatasvir (SOF/VEL) prophylaxis. Here we report new data on HCV transmission rates with 7-day prophylaxis (N=50) and cumulative outcomes of all D+/R- transplants (N=102) performed at our center so far.

Methods: Eligible D+/R- transplant recipients received escalating duration SOF/VEL over treatment groups (Group 1: 2 or 4 days; Group 2: 7 days) with first dose immediately pre-transplant. The primary outcome was the rate of HCV transmission from donor to recipient defined as a positive qNAT at 90 days post-transplant. Secondary outcomes included sustained virologic response at 12 weeks (SVR-12) after completion of HCV therapy, adverse events related to HCV infection and therapy, and allograft function compared with a contemporary matched cohort of HCV D-/R- transplants

Results: A total of 102 D+/R- transplants (mean age=52) were performed. Nine patients (9/102; 9%; 95%CI: 5%-16%) met the primary outcome of the development of HCV transmission by 90 days post-transplant with a three-fold decline across the two groups: Group 1 (7/52; 13%; 95%CI: 5%-25%) vs Group 2 (2/50; 4%; 95%CI: 0%-13%). All patients with HCV transmission achieved SVR-12 post-full course therapy. There was a higher incidence of peri-operative PPI use (3/9; 33% vs 10/93; 11%; p=0.05) and re-transplant status (2/9; 22% vs 0/93; p=0.007) among those with transmission vs those that did not. A 1:1 matched analysis with contemporary HCV D-/R- transplants (controls) showed that the pre-transplant wait time was shorter for D+/R- compared with D-/R- (mean: 1.8 vs 4.4 years; p<0.001). There were no differences in infections, rejection, development of de-novo donor-specific antibody, or transplant outcomes between controls vs cases up to 6 months of transplant. At the end of 6 months follow-up, two patients each in the D-/R- group and the D+/R- lost their transplant. Similarly, two patients died in the two groups by 6 months post-follow-up. For the D+/R- group, none of the patients with graft loss or death had HCV transmission. In a linear regression model adjusted for covariates, donor HCV status was not significantly associated with estimated GFR at 3- and 6-months post-transplant.

Conclusions: This paper describes extremely low transmission rate with a seven-day peri-operative DAA regimen. Compared with a matched HCV negative kidney transplant recipient cohort, D+/R- transplants had reduced wait times and comparable short-term kidney function outcomes.

Abstract# 360

Cost-Effectiveness Analysis of Short-Duration Anti-Viral Prophylaxis for Hepatitis C Positive Donor Kidney Transplants

I. Yakubu, Y. Zhang, S. Ijioma, N. V. Carroll, J. Patterson, R. Sterling, G. Gupta, *Virginia Commonwealth University Health System, Richmond, VA*

Purpose: Trials describing 4-12 week courses of direct-acting anti-viral drugs (DAAs) to treat hepatitis C virus (HCV) transmission from infected donors to uninfected kidney transplant recipients (D+/R- transplants), may be limited in application by costs and delayed access to expensive DAAs. A short prophylactic strategy may be safer and cost-effective. We report a cost-effectiveness analysis using the payer perspective to determine the least expensive DAA regimen, using published strategies.

Methods: Cost analyses comparing four strategies: 1) Seven-day DAA prophylaxis using generic Sofusbuvir/Velpatasvir (SOF/VEL) followed by a full course 12-week branded Glecapravir/Pibrentasvir (G/P) for those with HCV transmission (base case HCV infection rate: 4%; sensitivity analysis range: 1% - 13%); 2) Eight-day DAA prophylaxis using branded G/P followed by a full course 12-week branded SOF/VEL/VOX (voxilaprevir) for those with HCV transmission (base case HCV infection rate: 0%; sensitivity analysis range: 0% - 4%); 3) Four-week peri-operative DAA prophylaxis using generic SOF/VEL followed by 12-week branded G/P for those with HCV transmission (base case HCV infection rate: 0%; sensitivity analysis range: 0% - 1%); and 4) 'Transmit-and-treat' strategy with 8-weeks of G/P (assuming 100% transmission rate). The probabilities and costs (base case value and range; costs in 2020 US$) used in the model were estimated using current data from clinical trials and public databases. A decision tree was constructed to compare expected costs of each option, using a 6-month time frame. One-way sensitivity and threshold analyses were performed to account for uncertainty in the variable estimates for the two less expensive treatment options. All modeling and analyses were performed in TreeAge Pro Healthcare 2020.

Results: Cost analyses comparing strategies, showed that in the base case model, Strategy 1 was the least expensive (7-day SOF/VEL prophylaxis) with an expected cost of US $2,962, followed by Strategy 2 (8-day G/P prophylaxis; expected cost: $3,756), Strategy 3 (4-week SOF/VEL prophylaxis; expected cost: $5,538), and then Strategy 4 (8-week G/P treatment; expected cost: $26,294). The threshold value for Strategy 1 and 3 to break-even in expected cost was when the probability of infection with 7-day prophylaxis (SOF/VEL) equals 10.5%, when the daily cost of SOF/VEL equals $75.13, or when the daily cost of G/P equals $1,236.13. The threshold value for Strategy 1 and 2 to break-even in expected cost was when the probability of infection with 7-day prophylaxis (SOF/VEL) equals 6%, when the daily cost of SOF/VEL equals $311.24, or when the daily cost of G/P equals $298.38.

Conclusions: Short duration DAA prophylaxis using either 7 days of SOF/VEL or 8 days of G/P is more cost-effective than 4 weeks of SOF/VEL or 8 weeks of G/P and has the potential of resulting in significant cost-savings in a majority of D+/R- transplants.

Abstract# 361

Are Tacrolimus Concentrations Reduced with Direct-acting Antiviral Administration in Transplant Recipients?

K. Huang, K. Farrow, M. Christian, *Pharmacy, Penn State Health Hershey Medical Center, Hershey, PA*

Purpose: To evaluate the effects of direct-acting antivirals (DAAs) on tacrolimus trough concentrations and clinical outcome and to assess the need for a priori dose adjustments

Methods: In this single-center retrospective chart review, 164 liver, kidney, and heart transplant recipients with a diagnosis of hepatitis C virus (HCV) infection between October 1, 2014 and January 1, 2020 were screened. Those who were 18 years of age or older and starting DAA therapy with concomitant tacrolimus post-transplant were included. Patients were excluded if they were on concurrent moderate or strong CYP3A4 inhibitors or inducers; failed to complete DAA therapy; had HCV cure prior to transplant; or had missing labs at any of the following time points, including baseline, week 4 of DAA therapy, end of therapy, or sustained virologic response (SVR) at 12 weeks. The primary outcome was the percent change in tacrolimus trough concentrations at SVR12 compared to baseline. Tacrolimus doses and trough concentrations were examined at all above time points, and incidences of acute rejection, graft loss, and mortality were also reviewed.

Results: 46 patients were included in the final analysis, and regardless of DAA agent used, trough concentrations decreased by a median of 32.2% from an average of 6.99 ± 2.07 ng/mL at baseline to 4.65 ± 1.96 ng/mL at SVR12 ($p < 0.001$). Results of trough concentration differences are summarized in Table 1. Median total daily tacrolimus doses increased from 2.0 mg/day prior to DAA initiation to 3.0 mg/day at SVR12 (Figure 1). 15 patients (32.6%) required dose increases with DAA treatment, and two patients experienced an episode of rejection within this timeframe.

Conclusions: The treatment of HCV infection with DAAs leads to statistically significant reductions in tacrolimus trough concentrations. This is likely due to the improvement in liver enzyme function and metabolism, which seems to supersede anticipated DAA-tacrolimus drug-drug interactions. The clinical significance of these subtherapeutic changes are yet to be determined, but for patients on concurrent tacrolimus and DAA therapy, tacrolimus must be monitored closely, and empiric dose increases should be considered.

Table 1. Difference in Tacrolimus Trough Concentration Compared to Baseline

	Week 4	End of Therapy	SVR 12
Trough Concentration (ng/mL), Mean ± SD	5.24 ± 2.11	4.72 ± 2.30	4.65 ± 1.96
Trough Concentration Decrease (%), Median (IQR)	**23.4 (11.0 – 41.4)**	**35.6 (14.6 – 51.1)**	**32.2 (18.7 – 53.2)**
Paired Trough Concentration Difference (ng/mL), Mean ± SD	1.75 ± 1.95	2.27 ± 2.37	2.34 ± 2.25
95% CI, P-value	1.17 – 2.33, <0.001	1.57 – 2.98, <0.001	1.68 – 3.01, <0.001

Abstract# 362

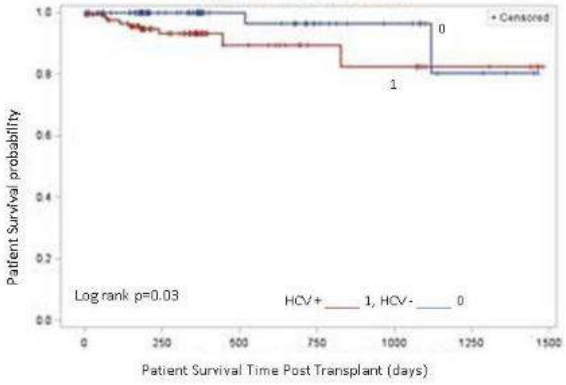
Outcomes of Kidney Transplantation from Hepatitis C Virus (HCV) Infected Donors Stratified by Recipient HCV Serostatus: A Mate Kidney Analysis

K. K. Sureshkumar[1], B. Chopra[1], R. L. McGill[2], *[1]Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA, [2]Nephrology, University of Chicago, Chicago, IL*

Purpose: Kidneys from donors infected with hepatitis C virus (HCV) are increasingly used for transplantation into HCV positive (+) recipients historically and into HCV negative (-) recipients in recent years with the intention to treat these recipients with highly effective directly acting anti-HCV agents in the post transplant period. The purpose of our study was to compare the outcomes of transplanting HCV + kidneys into HCV + vs. HCV- recipients using a mate kidney model in which one kidney from HCV + donor was transplanted into HCV + recipient and the mate kidney into HCV - recipient.

Methods: Utilizing the OPTN/UNOS database from January 2015 to December 2019, we identified HCV nucleic acid test (NAT) positive deceased donors where one kidney was transplanted into HCV + (antibody+or antibody + and NAT+) recipient and the mate kidney was transplanted into HCV antibody - recipient. The incidence of delayed graft function (DGF, defined as the need for dialysis within the first week of transplant), along with graft survival, death-censored graft survival and patient survival (using Kaplan-Meier method) were compared between the groups.

Results: Median study follow-up was 7 months. We identified 134 eligible HCV NAT+ deceased donors from whom one kidney was transplanted into HCV+ and the mate kidney into HCV- recipients. Proportion of mate kidney transplants increased over the years as follows: 5.2% in 2015, 7.5% in 2016, 10.5% in 2017, 33.6% in 2018 and 43.3% in 2019. DGF developed in 33 HCV+ and 30 HCV- recipients (p=0.7). During the follow up, there were 11 graft losses and 7 patient deaths in HCV+ group while there were 4 graft losses and 2 patient deaths in HCV- group. Kaplan-Meier analysis showed superior patient survival (log-rank p=0.03) in HCV- recipients (figure 1). Graft survival trended superior (log-rank p=0.06) and death-censored graft survival remained similar for HCV- vs.HCV+ recipients.



Conclusions: Our study showed increasing utilization of HCV NAT + donor kidneys for transplantation into HCV naive recipients in recent years. This reflects the availability of highly effective direct acting anti-viral agents to treat HCV infection. Improved patient survival and similar death-censored graft survival following the transplantation of HCV NAT+ kidney into HCV - vs. HCV + recipients indicate fewer death with functioning grafts in HCV- group. Superior patient survival in HCV- group is reflective of the overall better health status of HCV- compared to HCV+ kidney recipients.

Abstract# 363

Outcomes of Hepatitis C Nucleic Acid Testing Positive Donors in Aviremic Recipients With Delayed Direct-Acting Antiviral Initiation

M. Hudson, A. Webb, A. Logan, A. Silverman, A. Brueckner, *Pharmacy, Tampa General Hospital, Tampa, FL*

Purpose: The purpose of this study was to assess the clinical impact of utilizing hepatitis C virus (HCV) nucleic acid testing (NAT)+ donors in HCV NAT- solid organ transplant (SOT) recipients in a real-world practice where direct-acting antiviral (DAA) initiation is largely dependent on insurance coverage.

Methods: A single-center, retrospective chart review of HCV NAT- recipients who underwent SOT from a HCV NAT+ donor between 4/1/2019-5/27/2020 was conducted. The main objective of this study was to evaluate the sustained virologic response at 12 weeks (SVR12) after completion of DAA therapy. Secondary objectives were to assess the safety and efficacy of DAA therapy, as well as transplant related outcomes.

Results: Sixty-two HCV NAT- patients underwent SOT with a HCV NAT+ organ, with 59 transplant recipients included for evaluation: 22 kidney (KT), 18 liver (LiT), 10 heart (HT), 9 lung (LuT). HCV transmission occurred in 100% of recipients. Average time to DAA initiation was 46.7 ± 25 days after transplant. SVR12 was achieved in 97.8% (45/46; 13 patients lacked complete SVR12 data for primary endpoint analysis). Treatment failure occurred in 1 LuT patient on glecaprevir/pibrentasvir due to a P32del mutation, requiring alternative therapy with sofosbuvir/velpatasvir/voxilaprevir and ribavirin. 58.5% of KT, HT, and LuT patients experienced post-transplant liver dysfunction. No patients developed fibrosing cholestatic hepatitis. Two patients died, 1 secondary to anastomotic complication (LuT) and 1 due to pulmonary embolism (HT). De novo donor specific antibodies were present in 1 KT, 1 HT, and 2 LuT recipients, developing 402 days, 4 days, and a median of 137.5 (56-219) days post-transplant, respectively. Clinically significant rejection was diagnosed and treated in 1 HT patient (ACR2) and 1 LiT (RAI 5/9). No episodes of KT or LuT rejection were diagnosed. Six patients (10.2%) had documented adverse effects attributed to DAA therapy, including gastrointestinal, fatigue, orthostatic hypotension, and nail discoloration. One LuT required alternative therapy with sofosbuvir/velpatasvir due to intractable vomiting on glecaprevir/pibrentasvir, but successfully obtained SVR12.

Conclusions: This study adds to the paucity of literature describing the delayed start of DAA therapy for donor transmitted HCV in SOT and assuages the concerns of HCV sequelae by demonstrating efficacy via high SVR12 rates and no fibrosing cholestatic cirrhosis. This delay in DAA initiation shifts the financial burden to 3rd party insurances without compromising transplant related outcomes.

Table 1: Baseline Characteristics and Outcomes

Characteristics	Kidney (N=22)	Liver (N=18)	Heart (N=10)	Lung (N=9)
Hepatitis C genotype, n (%)				
1a	16 (72.7)	11 (61.1)	7 (70)	7 (77.8)

Abstract# 364

Transplanting Hepatitis C Infected Organs Into Uninfected Recipients: A Pharmacy Perspective

M. L. Holt, A. James, K. Gutierrez, T. Sparkman, J. Banbury, D. Jones, *University of Alabama at Birmingham Hospital, Birmingham, AL*

Purpose: Due to direct acting antivirals (DAAs), hepatitis C virus (HCV) positive patients are now resources for organ transplantation in HCV negative recipients. Our institution initiated a HCV donor positive/recipient negative (D+/R-) protocol that utilizes glecaprevir/pibrentasvir (G/P) in recipients of nucleic acid amplification testing (NAT) positive organs for 12 weeks beginning post-operative day three. Per protocol, NAT negative transplant recipients are initiated on treatment only after developing HCV viremia. Pharmacists play an integral role in G/P insurance approval and the medication acquisition process. The aim of this study is to assess antiviral efficacy and identify common barriers to G/P acquisition.

Methods: The current study is a single-center, cohort analysis of recipients of a kidney or liver transplant from a HCV positive donor transplanted November 2019-June 2020. The primary objective is to determine rate of sustained virologic response (SVR12). Secondary objectives are to describe G/P cost and evaluate the prior authorization (PA) process.

Results: Forty patients were included. Most patients were male (73%) African American (40%) renal transplant recipients (63%) who received anti-thymocyte globulin (58%). Thirty-one patients received NAT positive organs and were treated with G/P. The most common genotype was 1a (25%). All patients completed 12 weeks of therapy and achieved end of treatment response. No recipient of a NAT negative organ (n=9) developed viremia within the study period. All treated patients with a full data set available (87%) achieved SVR12. All G/P prescriptions required a PA with most (80%) requiring at least one appeal. The average time to PA approval was 3.35 days (range, 1-12). Pharmacy dispensing data was available for 27 patients indicating most patients required financial assistance (63%). Average copay, per fill, was less than $3.00 with average assistance equaling $1,265, $570 and $397 on each of three fills, respectively (range, $0-$3,892). Amounts rounded to nearest US dollar. Additional data collection is ongoing.

Conclusions: Preliminary results suggest that the HCV donor positive/recipient negative protocol appears to be safe and effective in abdominal transplant recipients. Pharmacy involvement ensured patients were able to obtain DAA treatment to facilitate discharge.

Abstract# 365

Use of Donor Blood Expedites HCV Genotyping and Allows Earlier DAA Initiation for Recipients of HCV+ Kidneys

B. Lonze, N. Ali, R. Montgomery, Z. Stewart Lewis, *Tranplant Institute, NYU Langone Health, New York, NY*

Purpose: Utilization of HCV viremic donor kidneys for transplant into HCV naïve recipients has become more widespread, yet best practices governing the initiation, timing or duration of direct acting antiviral (DAA) therapy are lacking. Most published series describe DAA initiation weeks to months after transplant. However, fibrosing cholestatic hepatitis has been reported with delayed DAA initiation. Herein we report our center practice utilizing donor blood for HCV genotyping to expedite DAA insurance approval and minimize the duration of recipient viremia.
Methods: Patients received education and DAA insurance benefits were ensured prior to listing for HCV+ organs. At the time of transplant, donor blood accompanying the kidney was used for HCV genotyping. Results were received within one week of transplant. Recipients were screened for HCV RNA by POD#4, and weekly for 12 weeks. Insurance authorization for DAA coverage was sought after both recipient viremia and donor HCV genotyping resulted. In 3 cases, donor viral load was insufficient for genotyping, and these recipients were genotyped once viremic.
Results: 80 hepatitis C naïve patients received hepatitis C positive donor kidneys between July, 2018 and October, 2020. 17 donors were HCV Ab+/NAT- and 63 donors were HCV Ab+/NAT+. All recipients of NAT+ donor organs became viremic; 89% were genotype 1a or 3. The median time to DAA initiation was 10 days for cases with donor genotyping (IQR 8-13). In contrast, the median time to DAA initiation was 20 days for the 3 cases with recipient genotyping (IQR 18-24). Median time from transplant to clearance of HCV viremia was 38 days (IQR 30-47) (Table 1). SVR12 was achieved in all patients, and no cases of fibrosing cholestatic hepatitis have been observed. There were 2 needlestick exposures of patient family members, though no HCV transmission occurred.
Conclusions: Early HCV genotyping using donor blood results in expedited initiation of DAA therapy for recipients of HCV+ kidneys. Compared to published reports, our patients are clearing viremia at the time that most other centers' patients are initiating DAA therapy. Whether duration of viremia or peak viral load are associated with adverse allograft events such as acute rejection is not known. The advantages to a shortened duration of HCV viremia remain to be characterized, but may include a lower risk of fibrosing cholestatic hepatitis and lower risk of HCV exposure to family members and caregivers. Our practice of expedited genotyping using donor blood is immediately implementable at all centers performing these transplants.

Table 1. Donor HCV Genotyping Expedites DAA Initiation and Viral Clearance

Days from Tx to viremia	3 (2-3)*
Days from Tx to start DAA (donor genotyped, n=60)	10 (8-13)
Days from Tx to start DAA (recipient genotyped, n=3)	20 (18-24)
Days from DAA start to clearance	26 (20-33)
Days from Tx to clearance	38 (30-47)
Days from viremia to clearance	35 (28-44)
Peak measured log viral load	5.01 (3.43-6.21)
Peak measured viral load	101,000 (2,682-1,640,000)

Live Kidney Donation

Abstract# 366

Long Term Outcomes of Kidney Donors with Fibromuscular Dysplasia

H. N. Adrogue[1], A. Evans[1], S. A. Hebert[1], H. E. Adrogue[1], D. T. Nguyen[2], D. Murad[1], E. A. Graviss[2], *[1]Medicine, Houston Methodist Hospital, Houston, TX, [2]Pathology and Genomic Medicine, Houston Methodist Hospital, Houston, TX*

Purpose: Fibromuscular dysplasia (FMD) is not an infrequent finding during kidney donor evaluation. Current guidelines do not provide any recommendations regarding the use of kidneys from donors with FMD and there is a paucity of published data on the outcomes of donors with FMD. This is an important issue in donor selection and long term donor outcomes since FMD can be present in many vascular beds.
Methods: We compared the development of hypertension, cardiovascular disease (CVD), proteinuria and reduced eGFR in 133 donors with FMD to 452 propensity score matched donors without FMD. The multivariable risks of these outcomes were determined by both logistic and Cox regression models. These donations took place between 1963 - 2007. The outcomes studied were ascertainable in 90-100% of the cohort.
Results: Donors with FMD were older (51 vs. 39 years), more likely to be women (80 vs. 56%), and had a higher systolic blood pressure at donation (124.7 vs. 121.3 mmHg), p <0.05 for all. Donors with FMD were less likely to have the left kidney removed (31 vs. 72%), p=.01. After a mean follow-up of 15.5 ± 8.9 years, a similar proportion of donors with and without FMD developed hypertension (22.2 vs. 20.8%), proteinuria (20.6 vs. 15.3%) and CVD (13.3 vs. 12.9%). No donor with FMD developed an eGFR <30 ml/min/1.73 m^2 or ESKD. The multivariable risk of these outcomes in donors with FMD was not elevated.
Conclusions: Donors with FMD were older (51 vs. 39 years), more likely to be women (80 vs. 56%), and had a higher systolic blood pressure at donation (124.7 vs. 121.3 mmHg), p <0.05 for all. Donors with FMD were less likely to have the left kidney removed (31 vs. 72%), p=.01. After a mean follow-up of 15.5 ± 8.9 years, a similar proportion of donors with and without FMD developed hypertension (22.2 vs. 20.8%), proteinuria (20.6 vs. 15.3%) and CVD (13.3 vs. 12.9%). No donor with FMD developed an eGFR <30 ml/min/1.73 m^2 or ESKD. The multivariable risk of these outcomes in donors with FMD was not elevated.

Multivariable risk mortality, cardiovascular disease, hypertension and reduced eGFR in propensity score matched cohort

	Logistic regression model		Cox proportional hazard model	
	Donors with FMD		Donors with FMD	
Outcome	aOR (95% CI)	p-value	aHR (95% CI)	p-value
Death	0.24 (0.05, 1.21)	0.08	0.64 (0.11, 3.65)	0.61
CVD	1.05 (0.53, 2.08)	0.88	1.04 (0.36, 2.97)	0.95
Hypertension	0.78 (0.38, 1.59)	0.49	1.41 (0.74, 2.68	0.30
Proteinuria	1.06 (0.58, 1.93)	0.85	1.04 (0.54, 2.01)	0.91
eGFR <60	1.04 (0.60, 1.80)	0.89	1.16 (0.83, 1.61)	0.38
eGFR <45	0.98 (0.49, 1.96)	0.96	1.26 (0.63, 2.52)	0.51

Covariates included: age, gender, body mass index (per kg/m^2), systolic blood pressure (per mmHg), fasting plasma glucose (per mg/dL), smoking, Center, donation year. Post-donation diabetes and hypertension were included in the Cox proportional hazard models at time-varying covariates.

Abstract# 367

Pre- Kidney Donation Pregnancy Complications and Long-Term Outcomes

E. Helgeson[1], E. F. Palzer[1], D. Vock[1], A. Matas[2], *[1]University of Minnesota School of Public Health, Minneapolis, MN, [2]University of Minnesota Medical School, Minneapolis, MN*

Purpose: In general, hypertension (HTN), proteinuria, or diabetes (DM) are exclusion criteria for living kidney donation in young candidates. Exceptions are made for conditions only experienced during pregnancy. In the general population, disorders of pregnancy are associated with increased long-term risk. There is little data on outcomes of women who had these complications and subsequently become donors. In a single-center analysis, we studied whether kidney donors who had pre-donation pregnancy complications (gestational HTN, preeclampsia, or gestational DM) were at increased risk of developing HTN, DM, and cardiovascular disease (CVD).
Methods: Donors with the specified pre-donation complication were matched 1:10 to donors with pre-donation pregnancies without the complication using nearest neighbor propensity score matching. Propensity scores were estimated using logistic regression with covariates for systolic BP, glucose, BMI, age, and creatinine at the

time of donation, donation year, relationship to recipient, and family history of HTN, DM, and heart disease. Incidence of outcomes were compared between groups using proportional hazards models.

Results: Of 1590 donors with pre-donation pregnancies, 47 had preeclampsia, 28 had gestational HTN without preeclampsia, and 36 had gestational DM. Matching led to good balance with SMDs < 0.1. Mean (SD) follow-up of those with pre-donation complications was 20.8 (12.8) years. Gestational HTN was associated with development of HTN (HR: 2.06, 95% CI: 1.25-3.40; p=0.004) and DM (HR: 2.92, 95% CI: 1.25-6.82; p=0.013). Gestational DM was associated with development of DM (HR: 4.17, 95% CI: 1.84-9.46; p=0.001). We did not detect associations between pregnancy complications and development of CVD or between preeclampsia and any of the outcomes.

Conclusions: In our single center study we found that among donors, who met screening criteria at the time of donation, having pre-donation gestational HTN or DM was associated with long-term risk. If confirmed by other centers: a) this data should be part of informed consent and b) accepting such candidates as donors should be done with caution.

Table 1: Association between pregnancy complications and long-term outcomes

		HR (95% CI); p-value for outcome		
Pregnancy complication	N	HTN	DM	CVD
Preeclampsia	47	0.93 (0.55, 1.57); 0.771	1.65 (0.69, 3.90); 0.258	1.60 (0.79, 3.22); 0.190
Gestational HTN	28	2.06 (1.25, 3.40); 0.004	2.92 (1.25, 6.82); 0.013	1.06 (0.48, 2.32); 0.887
Gestational DM	36	1.36 (0.74, 2.48); 0.321	4.17 (1.84, 9.46); 0.001	1.29 (0.39, 4.32); 0.676

Abstract# 368

The Risk of Post-donation Kidney Function Impairment for Prospective Living Kidney Donors with Persistent Isolated Microscopic Hematuria

J. v. Weijden[1], M. van Londen[1], I. M. Nolte[2], M. H. De Borst[1], S. P. Berger[1], *[1]Nephrology, University Medical Center Groningen, Groningen, Netherlands, [2]Epidemiology, University Medical Center Groningen, Groningen, Netherlands*

Purpose: According to current guidelines, a kidney biopsy is indicated in prospective living kidney donors who present with persistent isolated microscopic hematuria (PIMH) during evaluation, while post-donation risks of PIMH are unclear. Here, we investigated the risks of pre-donation PIMH on post-donation kidney outcomes.

Methods: We included 858 living kidney donors who underwent at least two urinalyses before donation and had yearly post-donation kidney function (estimated glomerular filtration rate (eGFR), proteinuria (assessed as the protein/creatinine-ratio (PCR)) and systolic blood pressure (SBP) measurements available. The association between pre-donation PIMH (at least two positive measurements with ≥ 1 red blood cell (RBC) per high power field or ≥ 5 RBC per μL) and post-donation kidney function was assessed using generalized linear mixed models.

Results: Mean age was 52 (11) and median [IQR] follow-up time was 36 [12-70] months. Pre-donation PIMH was present in 78 donors of whom 74% were female, versus 48% female in the non-PIMH group (P<0.001). There was no significant difference in post-donation ln(PCR), eGFR or SBP course between pre-donation PIMH and non-PIMH donors (0.01 and 0.03 increase/year for PIMH donors and non-PIMH donors, respectively; difference P=0.34), eGFR (0.41 and 0.33 increase/year for PIMH donors and non-PIMH donors, respectively; difference P=0.41), or SBP (1.24 and 0.93 increase/year for PIMH donors and non-PIMH donors, respectively; difference P=0.70), even after adjusting for pre-donation age, sex, BMI, pre-donation eGFR, SBP, and ACE inhibitor use.

Conclusions: We found no increased risk of post-donation proteinuria, higher blood pressure, or eGFR decline in donors with pre-donation PIMH. The need of a pre-donation kidney biopsy in donors with PIMH without other risk factors for kidney disease should be carefully reconsidered.

Abstract# 369

Living Donor Kidney Transplantation Racial Disparities Persist Independent of Social Vulnerability

A. C. Killian[1], M. C. McLeod[1], B. Shelton[1], R. D. Reed[1], P. MacLennan[1], H. Qu[1], B. J. Orandi[1], V. Kumar[1], D. Sawinski[2], R. M. Cannon[1], D. J. Anderson[1], M. J. Hanaway[1], J. E. Locke[1], *[1]University of Alabama at Birmingham Hospital, Birmingham, AL, [2]Hospital of the University of Pennsylvania, Philadelphia, PA*

Purpose: Living donor kidney transplantation (LDKT) confers a significant survival benefit over deceased donor transplantation. Racial disparities in access to LDKT are well recognized, yet they have increased in the last two decades. LDKT inequities have been largely attributed to contextual poverty and socioeconomic variability, however the association between LDKT and comprehensive measures of social vulnerability has not been characterized.

Methods: This retrospective study utilized the Scientific Registry of Transplant Recipients to identify adult, kidney-only transplant recipients between 1/1/2018-12/31/2018. Census tract-level data from the Centers for Disease Control and Prevention's 2018 Social Vulnerability Index (SVI), were linked to recipients by zip code. Logistic regression was utilized to evaluate the association between LDKT and SVI and race, controlling for patient- and community-level characteristics. Average adjusted predicted probabilities of LDKT across SVI were plotted by race.

Results: 20,380 kidney-only transplant recipients were included, of which 30% received LDKT. Higher SVI (e.g., greater social vulnerability) was significantly associated with lower odds of LDKT (adjusted odds ratio (aOR): 0.47, 95% confidence interval (CI): 0.40-0.57, p<0.0001). After controlling for SVI, African Americans (AAs) had 57% lower odds (aOR: 0.43, 95%CI: 0.39-0.48, p<0.0001) and other races had 45% lower odds (aOR: 0.55, 95%CI: 0.48-0.63, p<0.0001) of LDKT compared to their white counterparts. Average marginal effects for LDKT at the lowest SVI were 13% and 9% for AAs and other races, respectively, relative to white recipients (Figure 1).

Conclusions: Greater social vulnerability is significantly associated with lower odds of LDKT. Racial disparities in LDKT persist independent of social vulnerability, suggesting that other factors, such as sociocultural barriers and unconscious biases require greater attention to mitigate inequities.

Abstract# 370

Implications of Trends in Child to Parent Kidney Donation in Whites and African Americans

N. Jean, S. Krishnamoorthy, Y. Kyeso, P. Cunningham, N. Murthy, R. McGill, M. Josephson, *Nephrology, University of Chicago, Chicago, IL*

Purpose: Racial disparities in access to transplantation referral, wait listing and transplant receipt are well described. African Americans (AA) receive fewer living donor transplants than white (W) recipients. These quantitative differences are also accompanied by qualitative differences. Older single center studies have shown

more common child to parent donation in AA patients, and greater proportion of living unrelated donations in W patients. The purpose of this study was to evaluate whether these findings persist in the modern era and update the characteristics of donor-recipient relationships in the AA and W population using national registry data.
Methods: United Network for Organ Sharing (UNOS) Star files were used to generate a list of all living kidney donors since January 2001, and all of their adult recipients, in order to identify one cohort of living donor-recipient pairs who were AA-to-AA and another who were W-to-W. Donor/recipient age, sex, and relationships were examined. Age difference was calculated as donor age minus recipient age. The cohorts were compared, and differences evaluated with Wilcoxon tests and χ^2 as appropriate.
Results: 61,396 W-to-W and 10,998 AA-to-AA living donor-recipient pairs were identified. Median age difference was -7 years (IQR=22,1) in AA and -4 years (IQR=-19,2) in W (P<0.001). Figure 1 shows the distributions of age difference in AA-to-AA and W-to-W pairs. Unrelated kidney donation was more common in the W-to-W cohort at 46.7% compared to 25.9% in AA-to-AA cohort (P<0.001). Child to parent donation was more common in AA-to-AA cohort at 28.9% compared to 16% in W-to-W cohort (P<0.001). Daughters represented a larger percentage of living donors than sons in both groups: 9.0% vs 7.0% in W, and 15.4% vs 13.6% in AA (P<0.001). Among parental recipients (n=12,989), donation to mother was more common than to father in AA (56.6% vs 43.4%) but donation to father was more common than to mother in W (63.2% vs 36.8%) [P<0.001].
Conclusions: Differences in living donor-recipient relationships exist in AA and W. Given recent data showing increased risk of end stage kidney disease in child to parent donation in AA and the high proportion of children who donate to parents in the AA community, further study of the donation trends is warranted. Better understanding of cultural norms and pre-transplant evaluation strategies are required to explain this finding and its significance.

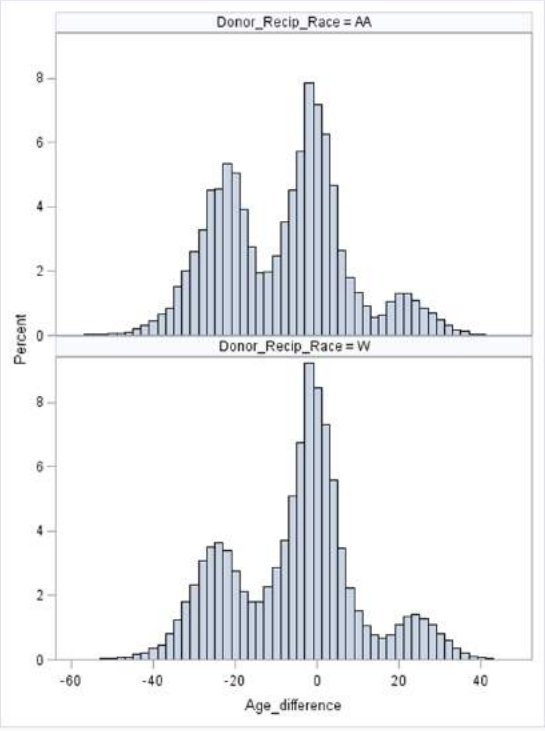

Figure 1. Histogram showing trimodal distribution of donor recipient age difference in both AAs and Ws, with a greater proportion of AA pairs with donors younger than recipients compared to W pairs.

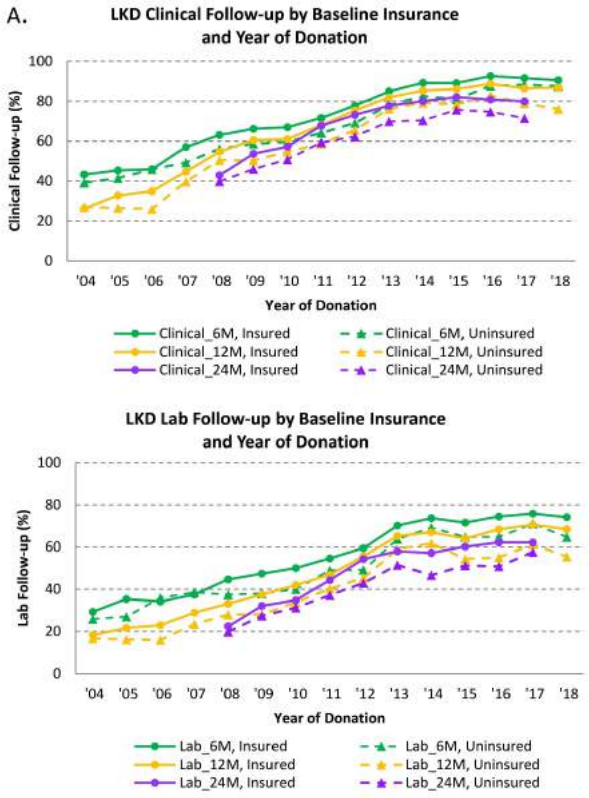
Abstract# 371

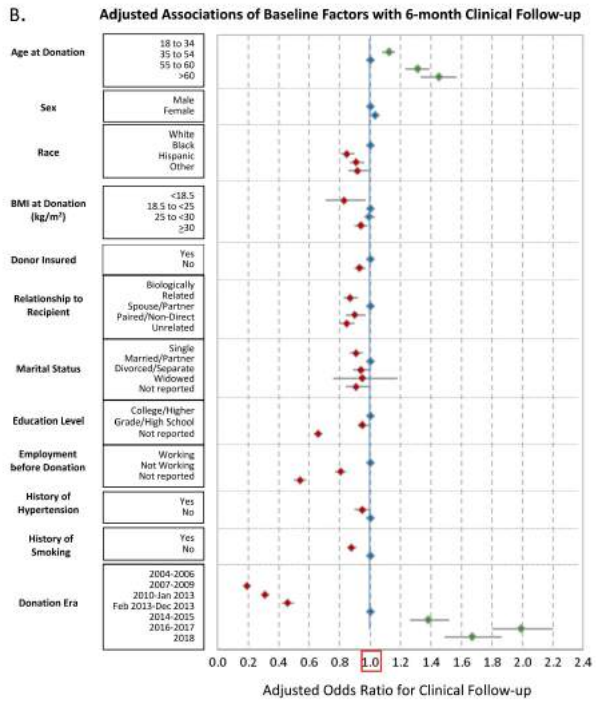
Associations of Lack of Insurance and Other Sociodemographic Traits with Deficiencies in Follow-Up After Living Kidney Donation

K. Lentine[1], R. Hays[2], N. Lam[3], A. Tietjen[4], A. Muiru[5], H. Xiao[1], A. Garg[6], C. Thomas[7], G. McNatt[7], R. Howey[8], U. Lebron-Banks[9], M. Cooper[10], M. Conboy[11], B. Kasiske[11], *[1]Saint Louis Univ, Saint Louis, MO, [2]Univ of Wisconsin, Madison, WI, [3]Univ of Calgary, Calgary, AB, Canada, [4]St. Barnabas, Livingston, NJ, [5]Univ of California, San Francisco, San Francisco, CA, [6]Western Univ, London, ON, Canada, [7]Univ of Iowa, Iowa City, IA, [8]Toyon Associates, Concord, CA, [9]New York Presb Hosp, New York, NY, [10]Medstar-Georgetown, Washington, DC, [11]SRTR, Minneapolis, MN*

Purpose: Follow-up after living kidney donation in the United States has improved with recent policy mandates. We hypothesized that lack of insurance at donation may be a barrier to postdonation follow-up.
Methods: We examined Scientific Registry of Transplant Recipients (SRTR) data for 90.460 living kidney donors (LKD) in 2004-2018 to examine associations (adjusted odds ratio, aOR) of insurance status and other baseline factors with clinical and laboratory follow-up after donation.
Results: Follow-up increased over time, and was especially high in older LKD. Follow-up was lower in uninsured compared to insured LKD over time, including in the era of the Affordable Care Act (**Fig. A**). In 2018, for uninsured vs insured LKD, respectively, clinical follow-up was 87.5% vs 90.4% at 6-months, and 76% vs 86.7% at 12-months, while 12-month lab follow-up was 55.4% vs 68.4%.



In multivariate regression including adjustment for donation year and other baseline factors, uninsured status was associated with 7% lower odds of 6-month clinical follow-up (aOR, 0.93) and 14% lower odd of lab follow-up (aOR, 0.86). Follow-up was also significantly (P<0.05) lower for LKD who were African American (aOR 0.85) or Hispanic (aOR 0.91), unrelated to their recipient (aOR 0.85), not working (aOR 0.81) and with less than college education (**Fig. B**).



Associations were similar for 1-year follow-up.

Conclusions: While follow-up after living kidney donation is improving, uninsured LKD and those who are non-white, unemployed, and with lower education are less likely to receive follow-up. Novel initiatives are needed to provide access to follow-up care for at-risk LKD, including the uninsured and under-insured, to minimize the risk of socioeconomic disparities in long-term postdonation outcomes.

Abstract# 372

Launching a National Living Donor Registry

J. E. Milton[1], M. Cooper[2], B. Hippen[3], *[1]Transplant Center, University of Texas Health San Antonio, San Antonio, TX, [2]MedStar Georgetown Transplant Institute, Washington, Colombia, [3]Metrolina Nephrology Associates, PA, Charlotte, NC*

Purpose: The National Donate Life Living Donor Registry launching in 2021 will allow 4000 persons a day the opportunity to become a living donor offering education and screening on demand, create a 'call to action' to add to national media stories and events, and provide infrastructure for 'living donor drives' that will not overburden staff at transplant centers.

Methods: A workgroup of donation and transplantation experts was convened to drive the creation of the registry. This group developed research and created education, questions and criteria for screening. The National Donate Life Living Donor Registry will be embedded in the National Donate Life Registry (registerme.org.) Prospects will be given information, complete screening questions and when answers meet predetermined thresholds will be mailed a no cost "test kit" for saliva to screen for blood type and HLA typing. The test results and health information will be linked and uploaded to a secure database completing the potential donor's registration which will be available to the transplant center selected by the prospective donor from a list driven by their geographical preferences.

Results: A nationwide survey of 500 qualifying adults: (Age 21-60, not opposed to organ and tissue donation) included 50% non-Hispanic Caucasian, 25-30% African American, 25-20% Hispanic or Asian and a nationwide sample of 50 previous living donors was conducted on the usability of web pages and to gain insights on design improvements. The results showed the web pages performed well in communicating the intended information and minor suggestions for improvement were received. Testing was completed on 40 saliva samples comparing the results of ABO and HLA saliva testing to serum testing from the same participants at two different labs to assess the use of saliva testing for initial screening. 100% of comparisons have come back as matches. Testing with simulated personal health information uploaded into the registry porta validated authentication procedures, data sharing techniques and ease of use accessing the registry portal, etc.

Conclusions: Each year 1.5 million Americans register as donors via the National Donate Life Registry, registerme.org. If 1 percent expressing additional interest in living donation are ultimately evaluated and cleared, an additional 15,000 living donors per year could occur. Even if only half of those donate 7,500 more lives would be saved. If these donors started a paired donation (KPD) chain (average = 3 transplants) up to 22,500 more lives could be saved. There were 6,867 living-kidney donor transplants in 2019. Use of the preexisting geographically agnostic organ donation registry to be the home of the living donor registry will generate even greater successes than evident in the Israeli model where a community organization has driven growth in altruistic living unrelated donor transplantation.

Abstract# 373

CT-measured Cortical Volume Ratio is an Alternative to Nuclear Medicine Split Scan Ratio Among Living Kidney Donors

J. Montgomery, C. Brown, A. Zondlak, K. Walsh, J. Kozlowski, A. Pinsky, E. Herriman, J. Sussman, Y. Lu, E. Stein, P. Shankar, R. Sung, K. Woodside, *Michigan Medicine, Ann Arbor, MI*

Purpose: The ^{125}I-iothalamate clearance and ^{99m}Tc-DTPA split scan nuclear medicine studies are used among living kidney donor candidates to determine mGFR and split-scan ratio (SSR). The CT-derived cortical-volume ratio (CVR) is a novel measurement of split-kidney function and can be combined with pre-donation eGFR or mGFR to predict post-donation kidney function. Whether pre-donation SSR predict post-donation kidney function better than pre-donation CVR and whether pre-donation mGFR provides additional information beyond pre-donation eGFR is unknown.

Methods: We performed a single-center retrospective study of 204 patients who underwent kidney donation between 06/2015-03/2019. The primary outcome was 1-year post-donation eGFR. Model bases were created from a measure of pre-donation kidney function (mGFR or eGFR) multiplied by the proportion that each non-donated kidney contributed to pre-donation kidney function (SSR or CVR). Multivariable elastic net regression with 1,000 repetitions was used to determine the mean and 95%CI of R2, root mean square error (RMSE), and proportion overprediction ≥15 mL/min/1.73m^2 between models.

Results: In validation cohorts, eGFR-CVR models performed best (R^2 0.547, RMSE 9.2 mL/min/1.73m^2, proportion overprediction 3.1%) whereas mGFR-SSR models performed worst (R^2 0.360, RMSE 10.9 mL/min/1.73m^2, proportion overprediction 7.2%) (P<.001 for all comparisons). R^2 and RMSE distributions are shown in Figures. The eGFR-CVR models had the smallest residuals among the lowest baseline eGFR decile (Figure).

Conclusions: These findings suggest that pre-donation CVR may serve as an acceptable alternative to SSR during donor evaluation and furthermore that a model based on CVR and pre-donation eGFR may be superior to other methods.

Surgical Issues and Deceased Donor Management

Abstract# 374

Cleveland Clinic Experience with Cadaveric Uterus Transplant

L. Del Prete[1], C. Quintini[1], K. Hashimoto[1], B. Eghtesad[1], G. D'Amico[1], C. Kwon[1], D. Priebe[1], E. Richards[1], S. Ricci[1], U. Perni[1], C. Ferrando[1], A. Chiesa-Vottero[1], S. Mawhorter[1], N. Yeaney[1], R. Farrell[1], R. Flyckt[2], C. Miller[1], T. Falcone[1], A. Tzakis[1], *[1]Cleveland Clinic, Cleveland, OH, [2]University Hospital, Cleveland, OH*

Purpose: Uterus transplantation (UTx) is the only treatment for women with uterine factor infertility (UFI). The majority of overall experience is from living donation. Little is known about live birth rates after embryo transfer and the long term outcomes of recipients with a uterus from deceased donors. We report here our updated experience with eight uterine transplanted patients from donors after brain death (DBD).

Methods: Recipient inclusion criteria were absolute UFI, BMI<30 kg/m^2, ages 18 to 45 and at least six frozen embryos ready to be implanted. Child-bearing age donors with no uterine abnormalities were considered for donation, prioritizing those who had a previous term pregnancy.

Results: Eight UTx from DBD have been performed since 2016. No injuries to donor's life-saving organs were reported. Mean procurement time was 249 min (158-367), whereas mean operative time was 537 min (334-870). The average cold ischemia time was 300 min (110-434) and mean hospital stay was 11 (5-30) days. All recipients are alive and well. Two patients had graft losses occurring on postoperative day (POD) 12 and 6. Two patients delivered healthy neonates, two patients are pregnant (second trimester) and two patients are undergoing embryo transfers. Reinstitution of menstruation occurred on average on POD 22. Three patients became pregnant with the first attempt. Graft rejection was observed and successfully treated in two patients (Table 1). No severe hypertension or preeclampsia occurred. Creatinine value average was 0.81, 0.89 and 0.92 respectively at 3, 6 and 12 months after UTx.

Conclusions: DBD procurement eliminates the burden of living donor comorbidities. Our findings indicate that UTx from DBD is a safe procedure with no renal impairment within 1-year follow-up. Although it is premature to state that DBD grafts are capable of establishing and carrying a pregnancy as a native organ, we do have encouraging preliminary evidence.

Table 1: Outcomes

	Postoperative Complications	Embryo Transfer Attempts	Pregnancy	Birth of Healthy Neonate
1	Hysterectomy due to arterial mycotic pseudoaneurysm (POD12)	NA	NA	NA
2	Grade 3 rejection	1	Grade 2 rejection; placenta previa and accreta	Yes
3	Reoperation for pelvic hematoma: DVT/PE; hemorrhagic ovarian cyst (POM2)	1	Hypertension; subchorionic hematoma	Yes
4	Biopsy related endocervical hematoma Post-transplant DM and elevated HbA1C	6	Not yet	NA
5	Hysterectomy due to vascular thrombosis (POD6)	NA	NA	NA
6	Re-exploration on POD1 due to poor window US; Grade 3 rejection	2	Ongoing with no complications (third trimester)	Anticipated Jan 2021
7	Incisional hematoma	3	Not yet	NA
8	None	1	Ongoing; abnormal second trimester bleeding	Anticipated March 2021

Abstract# 375

Pilot Study for the Use of Shortened Preemptive Therapy with Glecaprevir/pibrentasvir (g/p) and Ezetimibe in Hepatitis C Seronegative Solid Organ Transplant Recipients (Kidney and Heart) of Hepatitis C Viremic Donors

B. Aqel[1], H. Khamash[2], A. Moss[3], D. E. Steidley[4], R. C. Dickson[1], *[1]Gastroenterology and Hepatology, Mayo Clinic, Phoenix, AZ, [2]Nephrology and Hypertension, Mayo Clinic, Phoenix, AZ, [3]Transplant Surgery, Mayo Clinic, Phoenix, AZ, [4]Cardiology, Mayo Clinic, Phoenix, AZ*

Purpose: This prospective study aims to assess the efficacy of preemptive therapy with eight days of a combination of direct-acting antivirals (DAAs) (Mavyret) (Pibrentasvir /Glecaprevir) and Zetia (ezetimibe) in recipients of HCV viremic solid organ transplant (kidney or heart).Background: Zetia (ezetimibe), which is generally used as a lipid-lowering agent, was found to help blocking the cholesterol receptor used by the HCV virus for cell entry. The combination of this drug with DAA's can potentially be more effective in preventing the transmission of hepatitis C infection in recipients of solid organ transplants from donors with active viremia at time of procurement

Methods: This is a prospective open label. internally funded, single center study. Solid organ recipients (kidney, heart) who agreed to accept HCV viremic organs are consented for the study. Once patients are admitted for an HCV viremic organ, HCV pre-emptive therapy with Mavyret and Zetia was initiated upon call to the operative room. Mavyret was the choice in view of highly effective pan genotypic coverage, ability to use in the setting of advanced kidney disease, and low side effect profile. Combination therapy was continued for 7 days after transplant (total of eight doses). HCV RNA was monitored at day 0.1, 3, 7 and then weekly until 13 weeks post-transplant. SVR 12 was defined as undetectable HCV RNA 12 weeks after last dose of therapy (week 13 post-transplant)

Results: Eight patients have enrolled in the study so far (7 kidney transplants, one kidney pancreas transplant). All patients completed 8 days of combination therapy

without interruption. Patients tolerated treatment without and treatment related adverse events. All patients developed transient viremia by day 3 post-transplant with median peak viral load of 129 IU/ml (<15-1030). At day 7 post-transplant: 6/8 patients showed undetectable HCV RNA while 2/8 patients had detectable virus (<15). All patients achieved undetectable viremia at day 14 post-transplant. Two patients had follow up more than 13 weeks and both achieved SVR 12.

Conclusions: Early data confirm that preemptive therapy with shortened course with Pibrentasvir /Glecaprevir and ezetimibe was effective in recipients of non-liver solid organ transplants. Study continues to enroll and we anticipate the final data will be presented at the meeting. This approach may prove to be cost effective and will allow wider use of HCV viremic organs.

Abstract# 376

Donor Service Area Characteristics Impacting Liver and Kidney Deceased Donor Population

C. O. Warren, A. Zarrinpar, *Surgery, -University of Florida, Gaiinesville, FL*

Purpose: While there is ample evidence of racial and ethnic disparities in access to the waitlist, being transplanted, and post-transplant outcomes in liver and kidney transplantation, there has not been much investigation into the race/ethnicity of deceased donors (DD). Donor service areas (DSA) are tasked with providing access to allografts from their constituent populations. Although there are reports of lower donation rates in non-White populations, DSA specific factors affecting this have not been closely examined.

Methods: DSA specific adult liver and kidney DD data were obtained from the Scientific Registry of Transplant Recipient files between January 2013 and December 2018. Race/ethnicity distributions from each DSA (n=57) were compared to DSA population demographics as calculated from 2017 5-year estimate US Census data. DSA-specific characteristics were correlated with differences for Non-Hispanic White (NHW), Non-Hispanic Black (NHB), and Hispanic populations through logistic regression and scatterplots. Statistical analyses were conducted using SAS 9.4.

Results: NHBs were consistently overrepresented among deceased donors in the vast majority of DSAs when compared to the total population (liver 50/57, 86%) (kidney 38/57, 67%). NHW and Hispanic deceased donors were underrepresented as compared to the respective population of the DSA. Predictors of DSAs overrepresenting NHB liver donors were DSA population poverty (p-value=0.02), under high school education (p-value=0.02), and no insurance (p-value=0.02). No significant predictors were identified for NHBs in kidney donation or for NHWs in either liver or kidney donation.

Conclusions: Comparing donation rates to the total population, as opposed to the deceased population, highlights the overall health disparities in the general population. While further work is essential to fully understanding the underlying causes and potential remedies, the contradictory findings that indicate a lower than expected donation rate from "eligible donors" will need to be examined closely in light of these data. Further analysis is underway to understand additional factors associated with underutilization of donors in each DSA and to find potential ways to mitigate them.

Abstract# 377

Drones and Airplanes: Modeling the Potentially Deleterious Effects of Transportation on Shipped Organs

Y. S. Lee, J. S. Bromberg, J. R. Scalea, *Surgery, University of Maryland, Baltimore, MD*

Purpose: During the first shipments of human organs by drone, we identified significant differences in pressure and vibration that may adversely affect shipped organs. Liver transplants moved by aircraft have worse 1 year mortality rates than organs moved by ground. Further, 40 percent of primary non-function (PNF) amongst kidney transplants have no identifiable cause. Whereas donor and recipient organ function are monitored minute-to-minute, shipped organs are not monitored or tracked.

Methods: An animal model of MHC disparate heart transplantation was developed. Organ vibration during traditional flight was modeled using a tabletop vortex shaker to study the impact on transplant outcome. Hearts were exposed to vibration prior to transplantation.

Results: We previously reported on the first human transplant of kidney flown 2.8 miles by UAS, and we compared UAS with fixed-wing flight during which UAS demonstrated less vibration by more than 1.5G. Modeling shipment, fully MHC mismatched cardiac transplants were performed in mice. Vibrated hearts failed in 12 vs more than 45 days for controls (p=0.01). Vibrated hearts showed increased Annexin V+ (apoptosis) in the epicardium (3 fold) and myocardium (8-fold; p=0.01). TUNEL-positive cells increased within vibrated hearts 10-fold (p=0.01), suggesting increased cell death.

Conclusions: There is an unmet need to learn what environmental factors during shipment affect organ integrity. Understanding how organs are affected by the environment would allow for innovative solutions for shipment safety, organ allocation, and selection of mode of organ transportation.

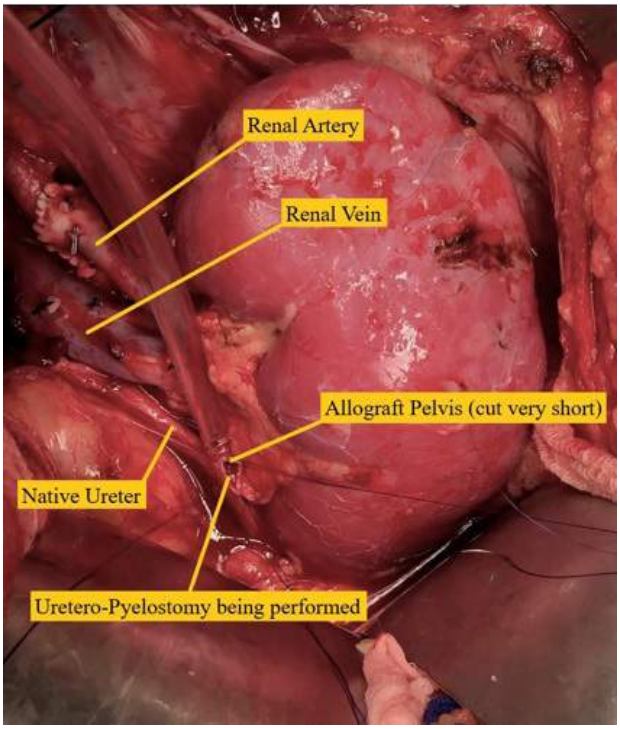
Abstract# 378

Primary Uretero-ureterostomy in Renal Transplantation

H. Shokouh-Amiri[1], M. S. Naseer[1], D. Aultman[1], R. McMillan[1], S. Tandukar[2], F. T. Siskron[3], N. Singh[2], G. Zibari[1], *[1]Advanced Surgery, John C. McDonald Regional Transplant Center - Willis Knighton Health System, Shreveport, LA, [2]Transplant Nephrology, John C. McDonald Regional Transplant Center - Willis Knighton Health System, Shreveport, LA, [3]Urology, John C. McDonald Regional Transplant Center - Willis Knighton Health System, Shreveport, LA*

Purpose: Uretero-neocystostomy (UN) is routinely performed in renal transplantation. Few studies of primary uretero-ureterostomy (UU) have been reported, showing its safety and feasibility. If the ureter is inadvertently cut short during procurement, the organ can still be used with UU or uretero-pyelostomy, avoiding discard. We started UU technique in 2016 to avoid the need for secondary UU. The aim of this study was to compare the incidence of urological complications and graft & patient survival between the two techniques.



Methods: From Jan 2009 to Aug 2020, we studied patients with Kidney (KT), Kidney-Pancreas (KPT), and Liver-Kidney (LKT) transplantation. Exclusion criteria included reflux as the cause of ESRD, en-block-KT, patients lost to followup before 5 years, and graft failure within 10 days. Data was collected on patient demographics, peri-operative findings, incidence of urine leak, stricture and fluid collection, and death-censored 5-year graft & patient survival. Categorical variables with Chi-Square test, continuous variables with Student's T-test, and survival analysis with Log Rank test were done using SPSS.
Results: Among 515 patients (KT=405, KPT=91, LKT=19), 190 had UU and 325 had UN. 4 patients were converted to UN intraoperatively due to atrophic ureter. In those who underwent UN, 6 patients required secondary UU. There was no statistically significant difference in incidence of urological complications. Foley catheter was taken out earlier and ureteral stricture developed earlier in UU patients (2.3 ± 1.5 vs 18.0 ± 22.9 months, p-value = 0.03). In KT, OR time was shorter in UU (2:39 vs 2:57, p-value = 0.05), and in KPT, death-censored 5-year graft survival rate was better in UU patients (100% vs 75.5%, p-value = 0.04).

Results						
	Total UU (n=190)	Total UN (n=325)	P-Value	KT UU (n=136)	KT UN (n=269)	P-Value
Age (Y), mean ± SD	48.5 ± 13.2	47.8 ± 0.52	0.52	49.5 ± 13.7	48.5 ± 12.5	0.42
Male, % (n)	61.1 (116)	57.5 (187)	0.43	61.0 (83)	56.9 (153)	0.42
Foley Catheter Duration (d), mean ± SD	4.0 ± 2.4	4.9 ± 2.1	0.01	4.0 ± 2.5	4.5 ± 1.5	0.17
Incidence of Leak, % (n)	1.6 (3)	0.6 (2)	0.28	2.2 (3)	0.7 (2)	0.21
Incidence of Stricture, % (n)	1.6 (3)	2.5 (8)	0.50	0.7 (1)	2.2 (6)	0.28
Incidence of Fluid Collection, % (n)	1.6 (3)	0.3 (1)	0.11	2.2 (3)	0.4 (1)	0.08
5-Year Death-Censored Graft/Patient Survival, %	96.8/ 93.2	89.2/ 92.9	0.49/ 0.06	95.6/ 93.4	91.4/ 92.2	0.46/ 0.23

Conclusions: UU is safe and easy to perform with comparable long-term results and has advantages of shorter OR time, removing Foley catheter earlier, and preventing organ discard and secondary UU.

Abstract# 379

Robotic Donor Nephrectomy: Advantages Offered by a Minimally Invasive Approach to Kidney Transplantation

A. Popovic[1], R. Shahbazov[1], A. Hoste[1], S. Loerzel[1], B. Gallay[2], J. Leggat[2], O. Pankewycz[1], R. Saidi[1], R. H. Dvorai[3], M. J. Hanlon[1], S. Narsipur[2], M. R. Laftavi[1], *[1]Surgery, SUNY Upstate Medical University, Syracuse, NY, [2]Medicine, SUNY Upstate Medical University, Syracuse, NY, [3]Pathology, SUNY Upstate Medical University, Syracuse, NY*

Purpose: Our aim was to further explore the difference in results between laparoscopic and robotic assisted techniques of living donor nephrectomies
Methods: This is a retrospective study analyzing the results of 71 consecutive live donor nephrectomies performed from May 2016 to October 2020, consisting of 33 laparoscopic and 38 robotic procedures. The two surgical approaches were compared by collecting information on operative length, intraoperative blood loss, intraoperative fluid administered, PRN opioids administered in hospital, length of stay, GFR and creatinine at discharge, and creatinine at 3, 6, and 12-month intervals
Results: Robotic and Laparoscopic operative techniques were found to have different operative length times (297min vs 263min, p=0.03) and different blood loss (83mL vs 155mL, p=0.025). RDN required significantly less intraoperative fluid replacement than their LDN counterparts (3.18L vs 4.41L p=0.00007). RDN patients also had a significantly increased GFR on day 1 post-operatively (64.5 vs 57.2, p = 0.013) and on day of discharge (68.7 vs 60.2, p = 0.023) but not at 1-month follow-up (64.9 vs 59.3, p = 0.12). There was no statistical difference in creatinine at discharge (1.11 vs 1.38 p=0.22), 3 months post-op (1.17 vs 1.21 p=0.73), 6 months post-op (1.15 vs 1.12, p = 0.79), or 12 months post-op (1.15 vs 1.13, p = 0.60).RDN patients experienced a non-significant 20% decrease in average length of stay (2.73 vs. 3.42 days p=0.78) but also a non-significant increase in Morphine milligram equivalents administered during their stay (1530 vs. 1470 p=0.88)
Conclusions: RDN is a safe and effective alternative surgical approach when compared to LDN. The decreases in blood loss and fluid administration and increased day 1 GFR may reflect the decreased tissue manipulation allowed for by robotic assistance. However, the novelty and learning curve of the technique may have contributed to the longer operative times seen in patients undergoing RDN

Abstract# 380

Does the NSQIP-Transplant Experience Demonstrate That Obese Kidney Transplant Recipients are Still at Increased Risk for Surgical Site Infections?

H. C. Yaffe[1], A. K. Belli[1], J. R. Parekh[2], D. L. Sudan[3], N. Elias[4], K. D. Conzen[5], D. P. Foley[6], R. Hirose[7], S. M. Greenstein[1], *[1]Surgery, Montefiore-Einstein Center for Transplantation, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [2]Surgery, University of California San Diego, San Diego, CA, [3]Surgery, Division of Abdominal Transplant Surgery, Duke University Medical Center, Durham, NC, [4]Surgery, Transplant Surgery Division, Massachusetts General Hospital, Boston, MA, [5]Surgery, Division of Transplant Surgery, University of Colorado Hospital, Aurora, CO, [6]Surgery, University of Wisconsin School of Medicine and Public Health, Madison, WI, [7]Surgery, University of California San Francisco, San Francisco, CA*

Purpose: The National Surgical Quality Improvement Program for Transplant (NSQIP-T) was designed to track surgical outcomes in adult liver and kidney transplants (KTX). The Pilot Beta Phase has captured data between March 1, 2017 and March 31, 2019, at 30 US centers. It is important to investigate how the pilot data informs us on recent outcomes. Increased BMI has historically been identified as a risk factor for SSI following KTX. We examined whether it is a risk factor for SSI in this cohort's KTX recipients.

Methods: Of the 3771 KTX recipients captured in NSQIP-T, 116 experienced at least 1 SSI. We divided the cohort into those who experienced an SSI (N=116) and those who did not (N=3655). We conducted univariate and multivariate log regression analyses to identify risk factors for SSI.

Results: Significant cohort demographic characteristics are listed in Table 1. On multivariate regression, BMI was found to confer increased risk of SSI. Table 2 lists the significant variables on multivariate analysis. The influence of BMI on SSI incidence was investigated by a ROC curve: AUC=0.66 (95%CI=0.61-0.71). The cutoff value was selected from the coordinates of the curve at BMI=27.5 kg/m^2.

Table 1. Significant cohort demographics

Parameter	SSI present (N=116)	SSI absent (N=3655)	P-value
African-American ethnicity	29.2%	21.7%	0.02
Employed	24.1%	36.6%	0.007
Non-private health insurance	69%	60%	0.008
Prior transplant	23.3%	13.9%	0.005
Diabetes mellitus	43%	30%	0.005
BMI	31±5.81 kg/m^2	27+36.7 kg/m^2	<0.001
Albumin	3.7±5.14 g/dL	3.8±5.07 g/dL	0.01
Operative time	200±76.0 min	186±80.8 min	0.02
Length of stay	5±8.11days	4±3.80 days	<0.001

Table 2. Significant risk factors for SSI on multivariate log regression

Parameter	OR	95%CI
African-American ethnicity	0.33	0.15-0.75
Employment	0.55	0.32-0.94
Prior Transplant	1.07	1.04-1.11
BMI	1.11	1.07-1.16
Length of stay	1.07	1.04-1.11

Conclusions: Increasing BMI persists as a risk factor for SSI in this cohort, but most accurately predicts an SSI at a non-obese BMI=27.5 kg/m^2. Therefore, obese and morbidly obese BMI cannot reliably be used in isolation as predictors of SSI in KTX recipients.

Abstract# 381

Successful Long Term Survival of Vascularized Composite Allografts After Extended Preservation at Subzero Temperatures Using Bioinspired Next Generation Cryoprotectants

M. Kline[1], S. Fidder[2], A. Callegari[1], A. Matoso[2], B. Oh[2], K. Lombardo[2], J. Etra[2], D. Vasilic[3], A. Childs[1], R. Redett[2], G. Brandacher[2], X. Wei[1], *[1]X-Therma Inc., Richmond, CA, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Erasmus MC, Rotterdam, Netherlands*

Purpose: Vascularized composite allotransplantation (VCA) is a viable reconstructive option for patients with devastating tissue defects. However, the field is constrained by short tolerable ischemia times. Extending tolerated ischemia time to days instead of hours would be transformative for VCA with regard to organ matching and exchange as well as allow for innovative protocols for recipient conditioning. We here present first outcomes using a novel organ preservation solution containing peptoids (XT-ViVo) for extended preservation of rat penile grafts for up to 72 hours in a syngeneic transplant model.

Methods: Lewis rats served as donors and recipients of heterotopic penile transplants. Grafts were flushed with heparinized saline and then directly transplanted (control, N=6) or perfused with either 5mL of HTK (control, N=18, stored at 4°C) or 5mL of XT-ViVo (intervention, N=24, stored at -5°C). HTK and XT-ViVo perfused grafts were preserved for 24, 48, or 72 hours prior to transplantation. Grafts were clinically monitored daily until study endpoints of POD3 and 30 and then assessed by histology (H&E) and by IHC (Caspase-3). RNA sequencing was performed to analyze inflammatory gene expression.

Results: All grafts with minimal ischemia showed no signs of clinical necrosis at POD3 or POD30. HTK preserved grafts all experienced distal necrosis at POD3 after preservation for 24, 48 or 72 hours. 5/6 of HTK grafts preserved for 72 hours were fully necrotic by POD30. In contrast, 24h and 48h XT-ViVo perfused grafts had excellent clinical outcomes at POD30; some epidermolysis was present in the grafts in the days before POD7, which subsequently resolved. 4/6 of 72h XT-ViVo perfused grafts showed distal necrosis at POD30 and 2/6 experienced only minimal distal epidermolysis and appeared clinically normal at POD30. In 48/72h distal tissue samples XT-ViVo grafts showed moderate inflammation and minimal necrosis, HTK grafts severe inflammation and major necrosis

Conclusions: We report the first VCA survival after 48-72 hours of preservation at subzero temperature with a peptoid-based cryoprotective solution

Abstract# 382

Economic Impact of a Pharmacist-Led Medication Safety Intervention: Report from the Transafe Rx Randomized Controlled Trial

D. Taber, J. Fleming, Z. Su, P. Mauldin, M. Gebregziabher, *Med Univ of South Carolina, Charleston, SC*

Purpose: We have previously demonstrated the efficacy of a pharmacist-led, mHealth intervention on reducing medication errors and adverse events leading to reduce hospitalizations in kidney transplant recipients through an RCT. Here we report the economic impact of the TRANSAFE Rx RCT by assessing the costs and return on investment (ROI).

Methods: This was an a priori planned economic analysis of the TRANSAFE Rx RCT; a 12-month, parallel arm, 1:1 randomized controlled clinical trial in adult KTX 6 to 36 months post-transplant (NCT03247322). All patients received usual post-transplant care, while those randomized to the intervention arm received supplemental clinical pharmacist-led medication therapy monitoring and management, via a smartphone-enabled mHealth app, integrated with risk-based televisits and home-based blood pressure and blood glucose monitoring. The clinical pharmacist conducted weekly risk assessments and recorded both pharmacological and nonpharmacological interventions performed throughout the study. We assessed estimated costs of hospitalizations using total charges multiplied by the 2019 CMS cost-to-charge ratio and assessing the ROI based on the costs saving vs. actual total costs required to deliver the intervention.

Results: 136 patients were enrolled, 68 were randomized into each arm. The mean age was 50.2 years, 51.5% of patients were male and 58.8% were AA. The primary etiologies of ESRD were hypertension (92.6%) and diabetes (27.9%). As previously reported, the intervention led to a 56% absolute reduction in medication errors (p<0.001), a 45% lower incidence risk of grade 3 or higher adverse events (p=0.048) and significantly lower rates of hospitalization (1.08 vs. 0.65 hospitalizations per patient-year; p=0.005); 20 patients in the intervention arm had a total of 38 hospitalizations with 99 hospital days, while 25 patients in the control arm had a total of 62 hospitalizations with 195 hospital days. Costs of hospitalizations were $1,531,071 in the control arm and $667,605 in the intervention arm. Costs to deliver the intervention included pharmacist time (342 hrs; $26,744), $57,012 to build and maintain the mHealth app, $25,709 for smartphone data plans and $1,675 for BP/glucose devices and supplies, totaling $111,140. The ROI for this intervention is estimated to be $7.8 saved for each $1 invested as the intervention had a net hospitalization cost-reduction of $752,326, or $11,063 per patient-year.

Conclusions: A pharmacist-led mHealth based intervention led to significantly fewer medication errors, adverse drug events and hospitalizations. The economic benefit of this intervention on reducing hospitalization costs is estimated to be $750,000, with a ROI of nearly 8 to 1.

Abstract# 383

A Cost Benefit Analysis of Different Minimal Access Donor Nephrectomy Techniques Performed at a Busy Transplant Centre

H. Sharma[1], A. Odougoudar[2], A. Sharma[2], D. Ridgway[2], A. Hammad[2], S. Mehra[2], *[1]Transplant and Vascular Access Surgery, Royal Liverpool University Hospital, Liverpool, United Kingdom, [2]Transplant and Vascular Access Surgery, Royal Liverpool Hospital, Liverpool, United Kingdom*

Purpose: We performed the cost-benefit analyses comparing Total Laparoscopic Retroperitoneoscopic donor nephrectomy (TLTLRPDN) versus Hand-assisted laparoscopic donor nephrectomy (HALDN) operations performed at our centre since 2011. Recently published cost figures of Robotic assisted donor nephrectomy (RADN) were used to compare our results.

Methods: We used a micro-costing approach to estimate the cost from the hospital perspective for N= 173 minimal access donor nephrectomies (N= 137 - TLRPDN; 35 - HALDN). Cost estimates took into account, sterilization costs for multiple-use equipment, costs for purchasing single-use equipment, staff, hospital stay and intraoperative medications and post-op analgesia. Quality-Adjusted Life Year (QALY) was assessed at 1-year post-operatively and then annually.

Results: The donor characteristics were similar in both groups: Median age 52.7 (26-78) years - TLRPDN/ 54 (25-74) years - HALDN, Median BMI 26.5±4 TLRPDN versus 27.2±5 HALDN, Mean PCA time 1.6 days TLRPDN versus 2.4 days HALDN, Mean Hospital stay 3.5 ± 1.2 days TLRPDN versus 4.1± 1.6 days. (p=NS) The average costs for a single non complicated TLRPDN was (total $12,203)- Theatre (Instruments, & Staff) $6,444; Ward-Stay $4968 and Other Costs (tests, drugs & PCA) $791. The average costs for a single non complicated HALDN was (total $13,390)- Theatre (Instruments & Staff) $7,251; Ward-Stay $4,967 and Other Costs (tests, drugs and PCA) $1,172. In comparison, the published data quotes average RADN theatre alone costs at $8913 . The average Quality Adjusted Life Year (QALY) at 1 and 3 years were 0.84/2.54 for TLRPDN and 0.79/ 2.32 for HALDN. The QALY gained with TLRPDN was 0.22, with cost per QALY gained at 3 years was $2,551.

Conclusions: TLRPDN provides cost-benefit compared to HALDN . More costing data needs to be published with regards to RADN.

Abstract# 384

The Use of Hcv Nat+ Organs in Hcv Negative Recipients with On-site Specialty Pharmacy Services: A Win for the Patient, the Transplant Center, and Society?

M. Person, N. Patel, W. Simerlein, H. Meadows, D. DuBay, D. Taber, *Medical University of South Carolina, Charleston, SC*

Purpose: Use of HCV AB positive organs (HCV AB+) with active viremia (NAT+) relies on appropriate and timely use of direct acting antiviral therapies (DAA). These are cost restrictive agents and thus, patient access to DAAs may be improved with the use of specialty pharmacy services (SPS). We hypothesized that on-site SPS improve patient access and adherence by facilitating the completion of prior authorizations and patient assistance while ensuring medication access and generating revenue for the institution.

Methods: This was a single center retrospective analysis performed from 1/1/2019-11/1/2020. Included patients are those who had documented HCV labs 12 weeks from the day of DAA initiation. For display of results, patients were divided by location of fill, either on-site SPS or an outside SPS. Primary outcomes were time to insurance approval and start of therapy, rate of adherence, patient out-of-pocket cost for 12 weeks of therapy, and revenue generated per patient.

Results: Sixty-four patients were included, 40 NAT+, and of those 25 had documented HCV labs at 12 weeks from DAA initiation and are included in these results. Of the patients that used on-site SPS, 25 (100%) required at least 1 prior authorization and 6 (24%) required an appeal for insurance approval. Use of the on-site SPS reduced the time to gain insurance approval by one-third (27 vs 20 days, **p=0.049**) and time to start DAA by roughly half, from 51 to 24 days (**p=0.004**). On average, patients that filled at on-site SPS had a total out-of-pocket cost of $10 for 12 weeks of DAA therapy and had 99.8% adherence to therapy. DAA therapy generated $38,964.45 of net revenue per patient for the institution per each 12 week treatment course. Kidney recipients that received an HCV AB+ organ waited 2.78 years on the transplant list, as compared to the average wait time at our institution of 4.35 (**p<0.01**) during a similar time period. One patient died during this time frame, though this patient received an HCV AB+ NAT- organ and did not require DAA therapy.

Conclusions: Utilizing HCV AB+ organs results in significantly shorter duration of time spent on the transplant waitlist. When NAT + organs are utilized, on-site SPS can facilitate a significantly shorter time to DAA insurance approval and initiation of therapy, while achieving very high adherence rates and generating a significant net revenue option for the institution. This represents the ideal win-win-win scenario.

Abstract# 385

Addressing a Need in Transplant Clinical Care: Creation of the Organ Transplant Caregiver Toolkit

H. Bruschwein[1], G. Chen[2], A. Ortega[3], W. Balliet[4], T. Coco[5], C. Thomas[6], B. Hansen[5], D. Richardson[7], K. Canavan[8], C. Burch[9], A. Yaldo[10], M. Jesse[11], *[1]University of Virginia School of Medicine, Charlottesville, VA, [2]Memorial Hermann Transplant Center, Houston, TX, [3]Memorial Transplant Institute, Miami, FL, [4]Medical University of South Carolina, Charleston, SC, [5]Mayo Clinic, Pheonix, AZ, [6]Banner Transplant Institute, Pheonix, AZ, [7]Caregiver, Minburn, IA, [8]National Kidney Foundation, New York, NY, [9]Stanford Children's Hospital, Palo Alto, CA, [10]University of Michigan, Ann Arbor, MI, [11]Henry Ford Transplant Institute, Detroit, MI*

Purpose: Lay or informal caregivers are a critical component of pre- and post-operative care in adult organ transplantation and living donation. Caregiving in organ transplantation has its own unique challenges and burdens. Despite the numerous demands placed on caregivers, there is currently no comprehensive educational resource for transplant caregivers. The Organ Transplant Caregiver Initiative held a consensus conference in October 2019, during which development of an educational toolkit for caregivers of adult organ transplant candidates/recipients/donors was discussed. A Caregiver Education Subcommittee was formed and tasked with creation of a toolkit. The goal of the toolkit is to provide essential, accessible, and timely education and resources to transplant caregivers.

Methods: The 11 member Caregiver Education Subcommittee met virtually throughout 2020 to develop content for the transplant caregiver toolkit. The toolkit is comprised of two primary sections as defined during the consensus conference, General content and Organ specific content, and multiple subsections (see Table 1). The Subcommittee assigned members to create a draft of each topic section. Drafts were shared and reviewed by subcommittee members during two virtual review meetings.

Results: A final draft has been reviewed by 14 external psychosocial reviewers and 7 organ transplant caregivers to obtain additional feedback. This process is currently under way and a final version of the toolkit will be sent to the AST Board for review in early 2021.

Conclusions: An accessible educational resource is needed for organ transplant caregivers and development of such a resource is underway.

Table 1. Transplant Caregiver Toolkit Sections

General Content	Organ Specific
• Transplant caregiver role and responsibilities • Legal and financial considerations for caregivers • Caregiver quality of life and self-care • Special considerations with caregiving • Caregiver Resources	• Kidney transplant • Heart transplant and mechanical circulatory support • Lung transplant • Liver transplant • Donor

Abstract# 386

Mhealth Family Self-Management Intervention for Families of Transplanted Children

S. M. Lerret[1], R. White-Traut[2], B. Medoff-Cooper[3], S. I. Ahamed[4], P. Simpson[5], R. Schiffman[6], *[1]Department of Pediatrics, Medical College of Wisconsin, Milwaukee, WI, [2]Children's Wisconsin, Milwaukee, WI, [3]University of Pennsylvania, Philadelphia, PA, [4]Department of Computer Science, Marquette University, Milwaukee, WI, [5]Department of Biostatistics, Medical College of Wisconsin, Milwaukee, WI, [6]University of Wisconsin Milwaukee, Milwaukee, WI*

Purpose: Nearly 2,000 children undergo solid organ transplant in the US annually. In our previous research with transplant families, parents reported difficulty coping with the complex care at home and decreased quality of life after hospital discharge. We evaluated the feasibility, acceptability and efficacy of a family self-management intervention (*myFAMI*) that employed an mHealth approach using an app and nurse response as a strategy for improving discharge transition outcomes.
Methods: In a randomized controlled trial design guided by the Individual and Family Self-Management Theory, we recruited family units (one primary and one secondary family member) of pediatric transplant recipients (standard care $n = 23$, *myFAMI* $n = 23$) at four US transplant centers. The *myFAMI* app promoted daily communication with the family member initiated by an in-app notification for 30-days after hospital discharge. Family members rated their coping, family self-management at home (medications, follow-up), and child symptom management (fever, pain, vomiting, diarrhea, or other illness). Pre-identified critical responses triggered an alert and subsequent nurse response to the family member within 2 hours. Post-discharge coping (Post Discharge Coping Difficulty Scale), self-efficacy (Self-Efficacy items), and quality of life (PedsQL Family Impact Module™) were assessed by telephone at 30-days after discharge. Analysis used descriptive statistics and t-tests.
Results: 44 of 46 enrolled family units completed study related procedures. Most *myFAMI* primary (82%, n = 18/22) and secondary family members (67%, n = 8/12) completed the app at least 80% of the time (24/30 days after discharge). 163 trigger alerts were generated by family members and were responded to by the nurse within 2 hours of receipt (100%). *myFAMI* family members had better outcomes at 30-days than standard care families: less coping difficulty (22 vs 26, p=0.59), improved self-efficacy (9.3 vs 9.0, p=0.08), and improved family quality of life (81.3 vs 75.0, p=0.47).
Conclusions: The *myFAMI* intervention was both feasible and acceptable. Findings from this preliminary study are clinically meaningful with effects in the expected direction that support further evaluation in a larger trial. Results advance knowledge and build the science from which to consider the use of *myFAMI* in post-discharge monitoring for other pediatric chronic illness populations.

Abstract# 387

Psychosocial Determinants of Regimen Adherence Among Kidney Transplant Recipients

A. Balakrishnan, S. Bailey, D. Mroczek, M. Serper, D. P. Ladner, M. S. Wolf, *Northwestern University, Chicago, IL*

Purpose: There is increasing evidence suggesting a high prevalence of inadequate medication adherence among kidney transplant recipients (KTRs) and its subsequent consequences on health outcomes. We sought to better characterize those individuals more likely to report problems with taking medication by examining associations of adherence with a range of psychosocial factors.
Methods: A cross-sectional analysis was performed using baseline data extracted from an ongoing clinical trial that enrolled 435 KTRs from two large transplant centers in Chicago, IL and Phoenix, AZ. Demographics, clinical characteristics, and social determinants of health (SDOH) that might contribute to any known disparities in medication adherence were assessed. Hierarchical generalized linear models were used to explore associations of key covariates with self-reported medication adherence, as measured by the Adherence Starts with Knowledge 12 (ASK-12) scale.
Results: Among our sample, 52% were non-Hispanic White, 60% male, and 48% employed, and 25% had public insurance coverage (Medicaid, Medicare, or dual Medicaid/Medicare). KTRs who were male, employed, had Medicare coverage alone, had limited health literacy, and reported poorer overall health and higher levels of depression experienced significantly greater problems with medication adherence.
Conclusions: SDOH, including limited health literacy, as well as overall health status and depressive symptoms, were most strongly associated with poorer medication adherence among a diverse sample of KTRs. Supplemental qualitative research will be conducted to further explore these and other factors in relation to medication adherence in greater detail.

Abstract# 388

Frequency and Types of Pharmacist Interventions and Risk Assessments Occurring During the 12-Month Transafe Rx Randomized Controlled Trial

H. M. Gonzales, J. N. Fleming, D. J. Taber, *MUSC, Charleston, SC*

Purpose: Clinical pharmacists have unique education and training to identify and mitigate medication (med) safety issues in high-risk populations, such as kidney transplant (KTX). The primary aim of the TRANSAFE Rx study was to assess the efficacy of a pharmacist-led, mHealth-based intervention at improving med safety issues in KTX, as compared to usual care.
Methods: This was an a priori planned secondary analysis of detailed interventions and risk assessments that occurred during a 12-month, parallel arm, 1:1 randomized controlled clinical trial in adult KTX 6 to 36 months post-transplant (NCT03247322). This intervention previously demonstrated reduced hospitalizations and adverse drug events. All patients received usual post-transplant care, while those randomized to the intervention arm received supplemental clinical pharmacist-led medication therapy monitoring and management, via a smartphone-enabled mHealth app, integrated with risk-based televisits and home-based blood pressure and blood glucose monitoring. The clinical pharmacist conducted weekly risk assessments and recorded both pharmacological and nonpharmacological interventions performed throughout the study.
Results: 136 patients were enrolled, 68 were randomized in the intervention arm and included in this secondary analysis. The mean age at baseline was 50.2 years, 51.5% of patients were male and 58.8% were black. The primary etiologies of ESRD were hypertension (92.6%) and diabetes (27.9%); 85.3% of patients were on dialysis at time of transplant. During the 12-month follow-up, the most common pharmacist intervention types included medication reconciliation (N=213) and patient education (N=144, Figure 1). Medication alterations, including additions, deletions, dose adjustments, schedule changes, interval changes, and dosage form changes, were also common. Medication reconciliation, study technology-related issues, prescription refills, and facilitating medication access largely remained consistent throughout the 12-month study period, while patient education and medication changes trended downward from Month 1 to Month 12 (Figure 2). From baseline to end-of-study, we observed an approximately 15% decrease in high-risk patients and a corresponding 15% increase in medium or low-risk patients (Figure 3).
Conclusions: A pharmacist-led mHealth based intervention may increase opportunities for both pharmacological and nonpharmacological interventions and reduce the number of high-risk patients in the KTX population.

Abstract# 389

Noninferiority Outcomes Among Undocumented Immigrant Kidney Transplant Recipients in California

H. Ichii[1], N. Eguchi[1], E. Tantisattamo[2], U. Reddy[2], A. Ferrey[2], D. Dafoe[1], *[1]Surgery, University of California Irvine, Orange, CA, [2]Medicine, University of California Irvine, Orange, CA*

Purpose: There are over 2 million undocumented immigrants (UI) in California, where currently, all individuals regardless of immigration status have equal access to kidney transplant(KT). There is a medical perception that UI face a higher risk of transplant failure due to language barrier, and lack of access to immunosuppressive medication and healthcare. Whether these characteristics of the minority are associated with poorer transplant outcome In UI compared to those of the US residents(UR) is uncertain.
Methods: A retrospective cohort study was conducted from a single transplant center during a 5-year study period. The study population was divided into UI and UR groups. All-cause mortality between the 2 groups was compared by using multiple Cox proportional hazard regression analysis. Other transplant outcomes including all-cause graft loss and acute rejection were examined by competing risks regressions with mortality and mortality plus graft loss serving as competing risks, respectively.
Results: Of all 306 consecutive kidney transplant recipients (KTR), mean age±SD was 47±13 years old, 173 patients were male (57%) and 73 (24%) were UD. During a median follow-up time of 3.25 years (0.04, 6.84), only 1 UI and up to 19 UR died (incidence rate of 0.023 and 0.004 person-years, respectively). Compared to the UI group, US group had no statistically significant increase in risk of all-cause mortality after adjusted for factors potentially contributing to KT outcomes (adjusted HR 5.33, p 0.153, 95% CI 0.54, 52.90, Figure 1A). The direction of the association between U.S. residential status and graft loss as well as rejection were the same as those of the mortality but the magnitudes were lower and remained non-statistically significant (s-$HR_{graft\ loss}$ 1.42, p 0.60, 95%CI 0.38, 5.33 and s-$HR_{rejection}$ 1.60, p 0.308, 95%CI 0.65, 3.94, Figure 1B&1C). Moreover, among 43 KTR receiving the 2nd KT, the UR group had 11% greater the risk for all-cause graft loss compared to the UI group but no statistical significance (HR 1.11, p 0.925, 95% CI 0.13, 9.67; Figure 1D).
Conclusions: The KT outcomes of the UI are not inferior to those of the UR; however, the UI have long been a minority in KT in the US. Transplant community and involved stakeholders may consider revisiting organ allocation policy to mitigate this disparity.

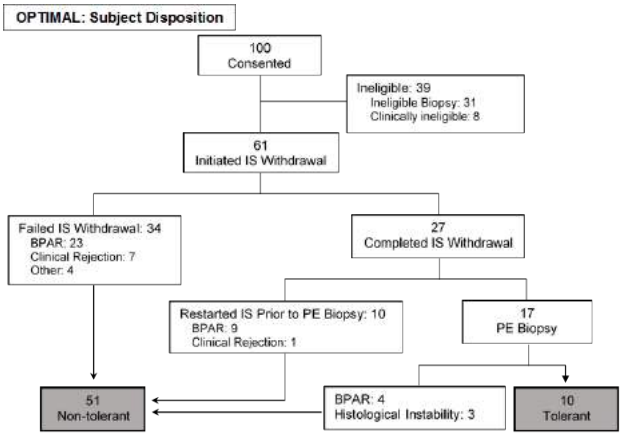
Abstract# LB 17

Primary Outcome of OPTIMAL: A Prospective Multicenter Trial of Immunosuppression Withdrawal (ISW) in Stable Adult Liver Transplant (LT) Recipients

S. Chandran[1], K. Mason[2], L. F. Sun[1], N. Tanimine[3], M. DesMarais[1], B. Burrell[1], J. F. Markmann[3], *[1]ITN, San Francisco, CA, [2]Rho, Inc., Durham, NC, [3]MGH, Boston, MA*

Purpose: To identify clinical & mechanistic correlates of successful ISW and operational tolerance (OT) in a selected cohort of adult LT recipients.
Methods: The Immune Tolerance Network ITN056ST study (OPTIMAL) enrolled non-autoimmune, non-viral adult LT recipients ≥3 years post-transplant with stable graft function on CNI-based IS. Eligible subjects without significant inflammation/fibrosis on a screening biopsy underwent phased ISW over 24-35 weeks. The primary endpoint was OT at 52 weeks following complete ISW, defined as no episodes of acute rejection and a liver biopsy showing histologic stability & absence of rejection by Banff criteria.
Results: Of 92 clinically eligible subjects who underwent screening biopsies, 61 had favorable histology and initiated ISW. Ineligible biopsies had inflammation (n=17) and/or fibrosis (n=9), bile duct damage (n=3), or arteriopathy (n=3). Subjects with favorable biopsies were significantly older at transplant (median age 56 vs. 47 years, p<0.01) and enrollment (median age 64 vs. 54 years, p<0.01), and more likely to have steatohepatitis (50.8% vs. 9.7%, p<0.01). No significant differences were observed in other parameters.
27 subjects completed ISW successfully. Of these, 10 met the primary endpoint (one additional subject did not meet biopsy criteria for OT but remained off IS). 34 subjects failed to complete ISW and 16 subjects restarted IS due to rejection or histologic instability. No significant differences were identified in the baseline clinical characteristics of tolerant and non-tolerant subjects. There were no cases of chronic rejection or graft loss.



Baseline Characteristics of Tolerant and Non-Tolerant Subjects		
	Non-tolerant (n=51)	**Tolerant** (n=10)
Age (yrs)	63 (56-68)	65 (55-69)
Time since transplant (yrs)	7 (5-11)	9 (4-13)
Deceased donor, n (%)	36 (70.6)	8 (80)
Male, n (%)	37 (72.5)	6 (60)
White race, n (%)	43 (84.3)	7 (70)
NASH as cause of liver disease	6 (11.8)	2 (20)
ALT (IU/L)	22 (17-29)	20 (17-25)

Conclusions: One in 3 clinically stable, long term adult LT recipients harbors subclinical allograft inflammation or fibrosis. A minority (16.4%; 95% CI: 8.2%-28.1%) of histologically and clinically stable LT recipients can successfully discontinue and remain off IS. Baseline clinical features do not appear to predict ISW outcome. Analyses are underway to identify histologic & mechanistic predictors of OT which could inform strategies to increase the success of ISW in future ITN studies.

Abstract# LB 18

Survival After Heart Transplant vs. Simultaneous Heart Kidney Transplant by Degrees of Renal Dysfunction at Engraftment in the United States: A Multivariable Analysis

S. M. Riad[1], M. Aljuhani[1], S. Jackson[2], T. Alexy[1], H. Wadie[3], C. Martin[1], R. Kandaswamy[4], *[1]Medicine, University of Minnesota, Eden Prairie, MN, [2]Complex Care Analytics, Fairview Health Services, Minneapolis, MN, [3]Transplant, Mayo Clinic, Jacksonville, FL, [4]Surgery, University of Minnesota, Minneapolis, MN*

Purpose: There has been a rising trend for utilizing kidneys in heart transplant candidates with different renal dysfunction degrees without established criteria to address this utility.

Methods: We analyzed the SRTR between 1/1/2000 and 9/31/2019. We identified all primary adult heart transplant recipients (HAT) and simultaneous heart kidney transplants (SHK). We sorted the recipients into four groups based on the degree of renal dysfunction at the time of transplantation: dialysis group, eGFR <20, eGFR 20-40 and eGFR>40-60 mL/min. Kaplan-Meier curves were generated to compare mortality by transplant type among the four groups. We analyzed predictors of mortality in each of the four groups separately. We used Cox proportional hazard models adjusted for recipient age, gender, race, diabetes status, heart transplant indication, ICU status, waiting time in weeks, transplant year, donor age, local vs. import organs, heart ischemia time and payor type. Follow-up was censored at five years post-transplant.

Results: Of the recipients with eGFR60 mL/min 14,728 received (HAT) and 1296 received (SHK). The proportion of SHK increased from 3% to 15% of all heart recipients over the study period. The proportion of SHK recipients with reasonably good renal function (>40-60 mL/min) before transplantation was 11.3%. In the multivariable Cox regression model for recipients in the eGFR >40-60 mL/min group, there was no survival benefit to SHK as compared to HAT (LLCI, **aHR,** ULCI) (0.61, **0.92**,1.39).In the lower the GFR groups, compared to HAT, SHK was associated with 35% better survival in the eGFR 20-40 mL/min group (0.49, **0.65**, 0.85), 68% improved survival (0.18, **0.32**,0.57) in the eGFR<20 mL/min group and 55% improved survival (0.34, **0.45**, 0.58) in the dialysis group.

Conclusions: Utilizing kidneys in heart transplant recipients with eGFR > 40 mL/min at the time of transplantation is an unwarranted use of a scarce resource.

Abstract# LB 19

Relationship Between %dd-cfDNA, MMDx Molecular Diagnoses, and Donor-specific Antibody in the Trifecta Study

P. F. Halloran[1], L. G. Hildago[2], J. Reeve[1], Z. Demko[3], A. Prewett[3], P. Billings[3], J. Truong[4], P. Vander Horn[4], &. Trifecta Study Group[5], *[1]Alberta Transplant Applied Genomics Centre, Edmonton, AB, Canada, [2]University of Wisconsin, Madison, WI, [3]Natera Inc., San Carlos, CA, [4]One Lambda Inc., West Hills, CA, [5]., ., AB, Canada*

Purpose: The Trifecta Study is a prospective multicenter investigator-initiated trial to evaluate the relationship between %dd-cfDNA and molecular biopsy findings at the time an indication biopsy as well as determining the relationship between %dd-cfDNA and DSA, measured either centrally or by the local center. (ClinicalTrials.gov # NCT04239703).

Methods: The present analysis compared the %dd-cfDNA measurements by Natera to HLA antibody as well as MMDx microarray molecular diagnoses in 176 biopsies: 109 no rejection; 38 ABMR; 4 possible ABMR; 14 TCMR, 3 possible TCMR, and 8 mixed. Central HLA antibody assessment was performed at One Lambda and interpreted by Dr. Luis Hidalgo using local genotyping. Each center also provided local DSA assessment and the histology diagnosis.

Results: The %dd-cfDNA was highly related to rejection in the biopsy (AUC 0.81), particularly active antibody-mediated rejection (ABMR) (AUC 0.82), and agreed more with MMDx ABMR than with histology ABMR (AUC 0.69; p=0.025). The association of %dd-cfDNA with pure T cell-mediated rejection (TCMR) was weaker (AUC 0.58). In 176 biopsies with DSA results recorded, DSA was negative in 136, positive in 30, and suspicious for nonspecific bead reactivity in 10. Molecular ABMR activity was frequently DSA negative, both centrally and locally, consistent with the increased recognition of DSA-negative ABMR. DSA associated with MMDx ABMR was usually class II. Because histologic ABMR requires DSA positivity for diagnosis, histology diagnosed fewer ABMR cases, but in DSA positive ABMR MMDx and histology usually agreed. Molecular ABMR classifiers predicted central DSA with AUC 0.77 (all) and 0.79 (class II) (figure 1A), and predicted central DSA better than local DSA (AUC 0.77 vs. 0.69) (figure 1B). The %dd-cfDNA predicted central DSA with AUCs of 0.71 (any DSA) and 0.73 (class II) (figure 1C). %dd-cfDNA predicted local DSA assessment less well than central DSA assessment (AUC 0.62 vs. 0.71) (figure 1D).

Conclusions: There is a strong relationship between %dd-cfDNA, centrally-measured DSA (particularly class II), and rejection, particularly active ABMR. These relationships are stronger for MMDx than histology diagnoses, and for central rather than local DSA assessments. Many ABMR cases are DSA-negative.

Abstract# LB 20

Disparities in Living Donor Follow-up During the COVID-19 Emergency Suspension of OPTN Follow-up Reporting Requirements

S. E. Booker, A. Henderson, L. A. Cartwright, S. Taranto, D. Klassen, J. L. Wainright, *UNOS, Richmond, VA*

Purpose: The OPTN temporarily suspended follow-up reporting requirements on 4/3/20 (retroactive to 3/13/20) in response to the COVID-19 crisis. We assessed the policy's impact on living donor follow-up form (LDF) and lab data submission for donors who have historically been disadvantaged in the transplant system.

Methods: We analyzed OPTN data as of 1/22/20 for all 6-, 12-, and 24-month LDFs expected between 3/13/20-12/31/20 ("COVID") vs 3/13/19-12/31/19 ("pre-COVID"). We assessed status of COVID forms by donor demographics. We also compared proportions of validated forms with complete lab data by era and donor demographics.

Results: 15.6% of kidney and 10.8% of liver LDFs were in amnesty status, with substantial variation by center. *Kidney:* We found significant differences in form status by race/ethnicity (p<0.001), gender (p=0.007), age group (p<0.001), neighborhood income quartile (p=0.001), and relationship to recipient (p<0.001), with greater proportions of forms in amnesty status for Black (Black: 19.3%; White: 15.6%; Hispanic: 13.7%; Other: 14.6%), male (male: 16.7%; female: 15.0%), younger (age 18-34: 16.9%; 35-49: 16.4%; 50-64: 13.9%; 65+: 13.7%), lower-income (Q1: 18.3%; Q2: 15.6%; Q3: 15.9%; Q4: 14.6%), biologically related and paired donors (biologically related: 16.8%; paired: 17.6%; spousal: 12.1%; unrelated: 14.5%) (Table 1). *Liver:* Younger donors had greater proportions of forms in amnesty status (age 18-34: 12.9%; 35-49: 10.0%; 50-64: 6.4%; p=0.056). Pre-COVID demographic differences in forms with complete lab data persisted during COVID, compounded by amnesty forms (Figure 1).

Conclusions: Centers have voluntarily submitted over 80% of expected LDFs under this emergency policy. However, our finding that a disproportionate number of forms are missing for donors who are Black, male, younger, lower SES, and biological relatives of their recipient is concerning. These groups are at greater risk of long-term complications after donation, and may have limited access to health services during the pandemic and risk being lost to follow-up. Centers should consider targeted follow-up efforts for at-risk groups.

Abstract# LB 21

Kidney Programs Can Filter Off a Majority of Their Unwanted Organ Offers without Harming Transplant Volumes

A. Toll, H. McGehee, R. McTier, D. Stewart, *Research, United Network for Organ Sharing, Richmond, VA*

Purpose: Evaluate if multifactorial filters can reduce unwanted kidney offers to centers, thereby reducing administrative burden and getting to the accepting candidate quicker.

Methods: 34 centers participated in the second phase of the OPTN Offer Filters Pilot which ran from August 26, 2020 to December 2, 2020. The OPTN preloaded a set of machine learning-derived recommended filters for each center prior to the start of the pilot. Recommended filters were derived using recursive partitioning trees based on centers' 2018-2019 acceptance practices and included donor profiles for which a center received offers from at least 20 donors with 0 acceptances. Centers were also able to create their own custom multi-factorial filters to reduce unwanted kidney offers. New in this phase, centers could identify specific candidate groups (high CPRA, 0-ABDR mismatch, age limits) who would still receive offers despite the donor profile. Additionally this phase introduced the ability to turn filters "on" to actually avoid receiving (bypassing) offers meeting filter criteria.

Results: 26 of 34 centers participating in the pilot elected to turn one or more filters on for bypassing. OPOs attempted to send 304,245 offers from 2,448 unique donors to these 26 centers. The centers' bypass filters removed 206,933 (68%) offers. Individual center bypasses ranged from 0% to 94% of offers (0% to 73% of

donors) filtered. Despite bypassing a large percentage of offers, pre-pilot transplant volumes closely mirrored those observed during the pilot ($R^2 = 0.88$, Fig 1A). In fact, bypassing more offers was slightly correlated with an increase in transplants during the pilot ($R^2 = 0.21$, Fig 1B). When weighting centers by their pre-pilot volumes, the pilot participants who turned filters on increased their transplant volumes by 5.4%, compared to a 3.1% decrease in non-pilot centers over the same period. Paired t-tests did not reveal a significant change in transplant volumes. Changes in offer acceptance observed to expected ratios before and during the pilot varied among the pilot centers and did not show trends different than the nation, even when broken out by KDRI.
Conclusions: The Offer Filters Pilot demonstrated both the potential of multifactorial filters to reduce unwanted organ offers and the willingness of centers to turn these filters on for bypassing. Despite bypassing a large proportion of offers, transplant volumes were not harmed. Some pilot centers were even able to increase their transplant volumes during the pilot, despite receiving upwards of 75% fewer offers.

Athena - Effect of Primary Immunosuppression on Development of De Novo Donor Specific Antibodies within First Year After Kidney Transplantation

W. Arns[1], A. Philippe[1], V. Ditt[1], I. A. Hauser[1], F. Thaiss[1], C. Sommerer[1], B. Suwelack[1], A. Finkel[2], C. Schiedel[2], D. Dragun[1], B. Nashan[1], *[1]ATHENA, Study Group, Germany, [2]Novartis Pharma GmbH, Nuremberg, Germany*

Purpose: The ATHENA trial [NCT01843348] investigated safety and efficacy of everolimus combined with cyclosporine A [EVR/CsA] or tacrolimus [EVR/TAC] *vs.* tacrolimus plus mycophenolic acid [MPA/TAC] in *de novo* kidney transplant [KTx] recipients. The herein described post-hoc analysis evaluates the impact of the primary immunosuppressive regimen on the development of *de novo* donor specific antibodies [DSA] and non-HLA antibodies, as well as on the clinical outcome, within the first 12-months [M] after KTx.
Methods: During this 12M randomized, open-label, prospective, controlled clinical trial, a total of 612 patients [pts] were enrolled in Germany and France. Pts were randomized at a 1:1:1 ratio to either EVR/CsA (C_0: 3-8 ng/mL during M1-12 and C_0: 75-125 ng/mL for M1-3; 50-100 ng/mL for M3-12, respectively), EVR/TAC (C_0: 3-8 ng/mL during M1-12 and C_0: 4-8 ng/mL for M1-2; 3-5 ng/mL for M3-12, respectively), or to the control arm MPA/TAC (C_0: 1440-2000 mg/d during M1-12 and 4-8 ng/mL for M1-2; 3-5 ng/mL for M3-12); all with steroids. Here, we report initial results on the development of *de novo* DSA as part of a post-hoc analysis on the per-protocol population [PP] (N=337) within the first 12M after KTx.
Results: The PP was comprised of n=80 pts in EVR/CsA, n=110 pts in EVR/TAC, and n=147 pts in MPA/TAC arm. Within the first 12M after KTx, only 7 pts in PP across all three treatment arms developed *de novo* DSA: n=4 in EVR/CsA, n=1 in EVR/TAC, n=2 in MPA/TAC arm. Further, only 2 of those 7 pts experienced a clinical event (BPAR) during the first 12M: n=1 in EVR/CsA and n=1 in MPA/TAC group; no graft loss or death was observed in this subset.
Conclusions: In this post-hoc analysis of the as to date largest randomized European KTx study ATHENA, initial findings reveal that the primary immunosuppression selected does not seem to have a significant impact on the development of *de novo* DSA. Moreover, development of *de novo* DSA within first 12M does not appear to have a direct effect on the resulting clinical outcome. Further analyses on *de novo* DSA as well as on non-HLA antibody (ET_A & AT_1) development and outcomes are currently ongoing to evaluate these findings in more detail.
In memoriam Duska Dragun, our dear friend and always inspiring colleague, who passed away much too early.

Predicted Heart Mass Difference as a Risk Factor for Severe Primary Graft Dysfunction in the Contemporary Era of Heart Transplantation: A Report from the International Consortium on Primary Graft Dysfunction

F. Foroutan[1], L. K. Truby[2], Y. Moayedi[1], J. Han[3], J. Guzman[4], M. Farrero[4], E. Baughan[5], M. Farr[5], H. Zafar[6], J. Felius[6], J. van Zyl[7], D. Law[8], S. Chih[8], P. Angleitner[9], M. Sabatino[10], A. DeVore[2], R. J. Miller[11], L. Potena[10], A. Zuckermann[9], K. K. Khush[3], S. A. Hall[6], H. J. Ross[1], *[1]Ted Rogers Centre for Heart Research, Toronto, ON, Canada, [2]Duke University School of Medicine, Durham, NC, [3]Stanford University, Stanford, CA, [4]Clinic Barcelona Hospital Universitari, Barcelona, Spain, [5]Columbia University Medical Center, New York, NY, [6]Baylor University Medical Center, Dallas, TX, [7]Dallas University Medical Center, Dallas, TX, [8]University of Ottawa Heart Institute, Ottawa, ON, Canada, [9]Medical University of Vienna, Vienna, Austria, [10]Bologna University Hospital, Bologna, Italy, [11]University of Calgary, Calgary, AB, Canada*

Purpose: Primary Graft Dysfunction (PGD) increases early mortality after heart transplant (HT). Predicted heart mass (PHM) difference may be a risk factor for PGD. Lack of granular data in registries limited our ability to validate its role in risk stratification for PGD. We used our recently developed International Consortium on PGD to evaluate PHM difference as a risk factor for PGD.
Methods: Total of 10 centers from Europe, US, and Canada provided data. Using the 2014 ISHLT definition, we identified cases of severe PGD. We calculated PHM for the left (LV) and right ventricle (RV) using the Multi-Ethnic Study of Atherosclerosis (MESA) equations. We calculated the %PHM difference between donors and recipients to investigate the association between PHM difference and severe PGD using a logistic regression model, adjusted for ischemic time and pre-HT LVAD.
Results: Between 2010 to 2020, we included 2,510 recipients, 634 females (25%), mean age of 53.9 ± 12.4 years. 8.4% were supported by IABP, 1.3% on ECMO, and 35% on LVAD pre-HT. Most donors were male (64.3%) with mean age of 36.5±13.0 years and ischemic time of 3.4±1.1 hours. A total of 196 recipients had severe PGD. Donor and recipient hearts were well-matched with a median total PHM difference of 2.1% (IQR -9.7 to 14.4%). The donor RV was typically oversized with a RV PHM difference of 12.7% (IQR 1.4 to 22.5%) and the LV slightly undersized with difference of -3.8% (IQR -16.6 to 9.9%). For every 10% increase in LV undersizing, there was a 16% increase in the odds of severe PGD. We observed no significant association between RV PHM difference and severe PGD.
Conclusions: Our International Consortium on PGD suggests under-sizing of the LV increases the risk of PGD. Future risk prediction models should integrate LV PHM difference as a risk factor for PGD.

Multivariable Logistic Regression Model for Severe Primary Graft Dysfunction		
	OR	95% CI
LV PHM Difference	1.16	1.02 - 1.32
RV PHM Difference	0.98	0.83 - 1.15

Abstract# LB 24

Liver Transplantation for COVID-19-associated Cholangiopathy

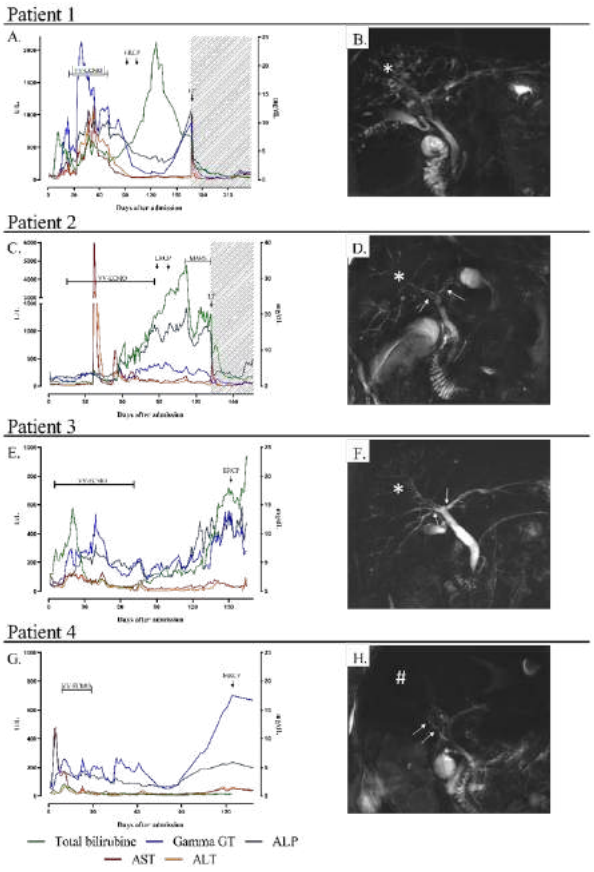
J. Blondeel[1], P. Meersseman[2], N. Gilbo[1], I. Jochmans[1], M. Sainz-Barriga[1], J. Pirenne[1], D. Monbaliu[1], *[1]Abdominal Transplantation Surgery, University Hospitals Leuven, Leuven, Belgium, [2]Medical Intensive Care Unit, University Hospitals Leuven, Leuven, Belgium*

Purpose: The hallmark viral pneumonia of coronavirus-19-disease (COVID-19) is often accompanied by important extra-pulmonary manifestations. Liver dysfunction occurs in up to 45% of COVID-19 patients, predominantly as moderate transaminitis whereas a cholestatic pattern is rare. Additionally, it is often described as inconsequential with negligible clinical impact. We describe the cases of 4 patients with COVID-19 who developed cholestatic liver injury that progressed towards a destructive cholangiopathy requiring liver transplantation in 2 patients.

Methods: Cases of all patients with COVID-19 admitted to our intensive care unit (ICU) between March and June 2020 were retrospectively reviewed for proven cholestatic injury. Additionally, patients referred to our liver transplant unit with a history of COVID-19 were also considered.

Results: Three out of 114 COVID-19 patients admitted to our ICU and one externally referred patient were considered for this case series. All patients suffered severe COVID-19 with need for mechanical ventilation, proning and extracorporeal membrane oxygenation. These patients all developed moderate to severe cholestatic liver injury after resolution of acute respiratory distress syndrome (Figure 1). The clinical presentation, cholangiogram, and histological findings were all typical of the critical care-associated condition 'secondary sclerosing cholangitis in critically ill patients' (SSC-CIP). Two patients ultimately required liver transplantation for refractory cholangitis.

Conclusions: The high incidence of this otherwise rare disease suggests that patients surviving severe COVID-19 are at increased risk of developing SSC-CIP. Several disease- and/or treatment-specific features may predispose to biliary ischemia and damage, while a direct pathogenic role of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) via cholangiocyte angiotensin-converting-enzyme-2 (ACE2) receptors is under investigation. We aim to raise awareness about the potential higher risk for SSC-CIP in patients recovering from severe COVID-19, and encourage early diagnosis and timely consideration of liver transplantation as the sole therapeutic option.



Shown are the temporal evolution of liver enzymes along with critical diagnostic/treatment events (left), a representative MRCP image (right) for each of the 4 patients (rows).

Gamma-glutamyltransferase (Gamma GT), alkaline phosphatase (ALP), aspartate transaminase (AST) and alanine transaminase (ALT) are projected on the left vertical axis and expressed as U/L, total bilirubin is projected on the right vertical axis and is expressed as mg/dl. VV-ECMO: veno-venous extracorporeal membrane oxygenation, ERCP: endoscopic retrograde cholangiopancreatography, MARS: Molecular Absorbent Recirculating System, LT: liver transplantation.

Abstract# 460

Complement Blockade Improves Renal Xenograft Survival in Primates in the Absence of Transgenic Complement Regulatory Proteins

D. A. Faber[1], B. Lovasik[1], A. Matar[1], C. Breeden[1], A. B. Farris[2], M. Tector[3], A. Tector[3], A. Adams[4], *[1]Surgery, Emory University School of Medicine, Atlanta, GA, [2]Pathology, Emory University School of Medicine, Atlanta, GA, [3]Surgery, University of Miami, Miami, FL, [4]Surgery, University of Minnesota, Minneapolis, MN*

Purpose: Complement activation is a major contributor to xenograft rejection. To minimize xenograft injury, complement suppression via insertion of human complement-regulatory transgenes into the donor pig genome has been previously evaluated; however, genome modification is of undefined efficacy and risk. As such, pharmacologic complement regulation is a viable option to suppress complement activity in the absence of transgene insertion in the donor pig. The aim of this study was to assess the efficacy of terminal complement blockade using a novel, clinically relevant anti-C5 mAb (tesidolumab, LFG316) in a pig-to-NHP renal xenotransplant model using non-transgenic pig donors.

Methods: Porcine donors were engineered without GGTA1/B4GALNT2 (DKO) or GGTA1/B4GALNT2/Class I SLA (TKO). In vitro assays were performed combining xenoreactive rhesus macaque serum with porcine peripheral blood mononuclear cells (PBMCs) in the presence of complement and tesidolumab. Kidney xenotransplants were then performed from porcine donors to rhesus macaques (n=17). Recipients received T-cell depletion plus either anti-CD154 (clone 5C8) and tesidolumab (n=7), or anti-CD154 alone (n=10).
Results: Incubation of tesidolumab with porcine PBMCs and xenoreactive NHP serum impaired complement-mediated cytotoxicity in a dose-dependent manner. Anti-C5 therapy significantly prolonged xenograft survival (MST >350 days) compared to treatment with anti-CD154 alone (MST 9 days, p=0.0118). The combination of xenoantigen knockout and treatment with anti-CD154 prevented the formation of de-novo anti-pig antibody.
Conclusions: Transient terminal complement blockade using tesidolumab significantly prolongs graft survival and prevents early antibody-mediated xenograft rejection in a pig-to-NHP renal transplant model using porcine donors without transgenes. Selective knockout of GGTA1/B4Gal/SLA-I xenoreactive antigens on the cell surface allows for long-term graft survival and prevents development of xenoreactive DSA. These data suggest that therapeutic terminal complement blockade permits successful xenotransplantation without the need for multiple complement regulatory transgenes.

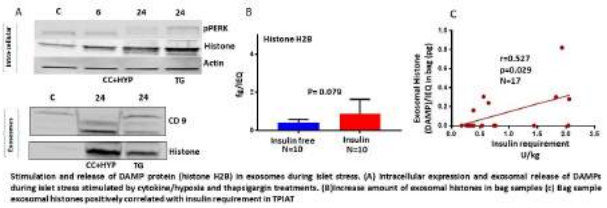
Abstract# 461

Exosomal DAMP Proteins Released During Islet Isolation Affects TPIAT Outcomes

P. Saravanan, J. Kalivarathan, M. Levy, M. Kanak, *Hume Lee Islet Cell Transplantation Lab, Department of Surgery, VCU Health, Richmond, VA*
Purpose: Isolation of islets cause significant stress that results in the release of immunogenic factors called damage-associated molecular patterns (DAMPs) which can induce inflammatory signaling that results in post-transplant islet damage. Here, we sought to identify these DAMPs released by islets via exosomes during islet isolation and also study their effect on TPIAT outcomes.
Methods: Post-transplant stress was mimicked *in vitro* by exposing human islets to hypoxia and cytokines (Cyt+Hyp) simultaneously for 24h. Separately, human islets were also treated with thapsigargin (TG) for 24hrs to induce ER stress. Exosomes were isolated and the differentially expressed proteins were determined by mass spectrometry and western blotting. Exosomes were also isolated from the transplant media (infusion bag) of TPIAT patients to measure DAMP protein levels in them. Patients receiving an islet dose of 4000IEQ/kg were divided into insulin-dependent (ID; n=10) and insulin-independent (IID; n=10) groups. The exosomal DAMP protein levels were correlated with 1-year TPIAT outcomes
Results: The number of exosomes released was significantly elevated in (Cyt+Hyp) treated islets compared to untreated islets. The mass spectrometry analysis has revealed about 17 proteins including DAMP protein histones (H2A, H2B, H4) and Keratins (Type I and II) were differentially expressed. Islets treated with thapsigargin or Cyt+Hyp overexpressed histones and keratins intracellularly through the activation of the PERK/IRE1α pathway. This subsequently led to the increased release of histones and keratins via exosomes during stress (Figure A). Exosomes isolated from transplant media of TPIAT patients showed elevated histone (p=0.0796) (Figure B) and decreased keratin (p=0.072) in ID compared to IID patients. Moreover, high exosomal histone/IEQ correlated with increased insulin requirement (r=0.527, p=0.029 n=17) (Figure: C) and HBA1c%, and lower c-peptide (r=-0.494, p=0.085 n=13) and SUITO index at 1-year POD. In contrast, the exosomal keratin/IEQ showed the opposite effect on 1-year outcomes
Conclusions: The study has identified the exosomal DAMP protein-like histones are produced by the stressed islets during islet isolation which is capable to induce islet inflammation and graft loss in TPIAT. The elevated quantity of such exosomal DAMP proteins in the bag samples correlated with the poor transplant outcomes in TPIAT



Stimulation and release of DAMP protein (histone H2B) in exosomes during islet stress. (A) Intracellular expression and exosomal release of DAMPs during islet stress stimulated by cytokine/hypoxia and thapsigargin treatments. (B)Increase amount of exosomal histones in bag samples (c) Bag sample exosomal histones positively correlated with insulin requirement in TPIAT

Abstract# 462

Selective Regulatory T Cell Expansion by a Novel IL-2 Mutein Prolongs Skin Transplant Survival in Mice

T. J. Borges[1], O. Effe[1], R. B. Gassen[1], A. Al Jurdi[1], I. T. Lape[1], G. J. Babcock[2], S. M. Carlson[2], J. C. Madsen[1], L. V. Riella[1], *[1]Center For Transplantation Sciences, Massachusetts General Hospital, Charlestown, MA, [2]Visterra, Inc., Waltham, MA*
Purpose: Long-term immunosuppression predisposes transplant patients to a greater risk of infection, malignancy and kidney toxicity. Hence, alternative methods to regulate the immune system are needed. Low-dose IL-2 therapy has been reported to expand Tregs *in vivo* but can promote the proliferation of unwanted effector cells such as cytotoxic T cells and natural killer (NK) cells. This led us to develop and test a novel human IL-2 mutein (mIL-2) fused with a human antibody Fc domain (IL-2-Fc), designed to selectively induce Tregs with minimal effects on effector cells. Herein, we investigate the immune regulatory effects of mIL-2 in transplantation.
Methods: We initially performed *in vitro* experiments in which we stimulated mouse splenocytes with the wild-type IL-2-Fc, the mIL-2, or negative control. We next performed a minor-mismatch murine skin transplant model, in which B6 males skins were transplanted into B6 females recipients (n= 4 mice/group). Mice were treated subcutaneously twice weekly with either PBS or 0.5 mg/kg of the mIL-2.
Results: We found that the mIL-2 increased the levels of phosphorylated STAT5 (a downstream molecule of the IL-2 receptor) selectively in Tregs, with minimal effects on NK cells, non-Tregs CD4+ T cells, and CD8+ T cells. We next investigated whether mIL-2 treatment would lead to a sustained Treg expansion and prolongation of skin graft survival. We found that mIL-2 alone significantly prolonged the allograft survival when compared to the PBS group (MST 20.5 vs 47.5, *p= 0.0067*; Fig. 1A). The treatment with mIL-2 led to a significant increase in circulating Tregs, peaking at day 10 post-injection and followed by a stabilization of the Treg frequency at ~25% (Fig. 1B). Importantly, we observed no effect of mIL2 on effector immune cells such as NK cells (Fig. 1C), and CD8 T cells (not shown) when compared to the PBS group. Moreover, mIL-2 increased Tregs suppressive function as observed by an *ex vivo* suppression assay (Fig. 1D). Extending these findings, mIL-2 significantly expanded circulating Tregs with no detectable effects on Teff or NK cells in cynomolgus monkey (not shown). Our data also demonstrated that the mIL-2 has a >10-fold longer half-life than reported for recombinant IL-2.
Conclusions: Overall, our data suggest that mIL-2 prolongs graft survival by the selective and sustained expansion of Tregs while also enhancing Treg function.

Abstract# 463

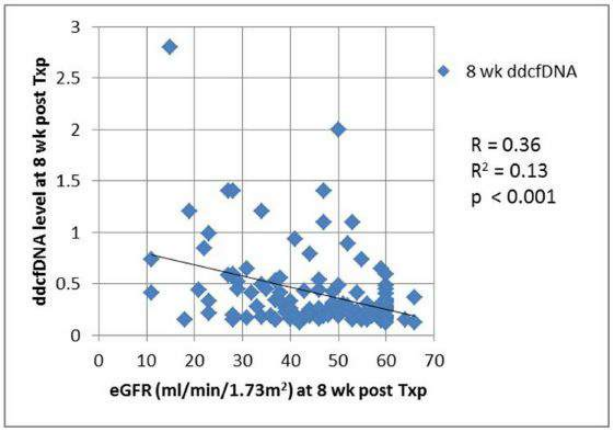
Allograft Function and Baseline Donor Derived Cell Free DNA in Kidney Transplant Recipients: One Size Doesn't Fit All

K. K. Sureshkumar, A. Grazier, B. Chopra, *Allegheny General Hospital, Allegheny Health Network, Pittsburgh, PA*

Purpose: Donor derived cell free DNA (dd-cfDNA) is increasingly used to predict acute rejection in kidney allografts . Cell free DNA fragments are constantly released into the circulation through cellular senescence and injury. DNA fragments are cleared from the blood by kidney and liver with a short half-life of around 30 minutes. It is unclear whether reduced estimated glomerular filtration rate (eGFR) in kidney transplant recipients (KTRs) would result in higher baseline dd-cfDNA values. We aimed to explore the variations in baseline dd-cfDNA at differing levels of eGFR in stable KTRs.

Methods: Our center has been doing for-cause and surveillance (high immunologic risk) dd-cfDNA in KTRs using AlloSure (CareDx, Brisbane, CA). We identified patients who underwent kidney transplantation between September 2017 and June 2020 and had dd-cfDNA levels at or around 8 weeks post-transplantation. A dd-cfDNA value ≥ 1% prompted allograft biopsy. KTRs with biopsy evidence for rejection or other injuries were excluded from the analysis. Patients were divided based on GFR estimated with MDRD equation using 8-week serum creatinine (<30, 30-59 and ≥60 ml/min/1.73m^2). Baseline 8-week dd-cfDNA levels were compared between different eGFR groups using t-test.

Results: A total of 156 patients were identified during the study period. We excluded 36 patients with biopsy evidence of rejection from the analysis. The remaining 120 patients (66 males and 54 females) were available for the analysis including 11 with re-transplants. Among the study group, 40 patients had living and 80 had deceased donor kidney transplantation. Patients were stratified based on eGFR as follows: <30 ml/min/1.73m^2 (n=18), 30-59 ml/min/1.73m^2 (n=72), ≥60 ml/min/1.73m^2 (n=30). Baseline 8-week dd-cfDNA values were significantly higher in groups with eGFR <30 vs. ≥60 ml/min/1.73m^2 (0.74±0.65 vs. 0.25±0.12, p=0.005); <30 vs. 30-59 ml/min/1.73m^2 (0.74±0.65 vs. 0.38±0.34, p=0.03) and 30-59 vs. ≥60 ml/min/1.73m^2 (0.38±0.34 vs. 0.25±0.12, p=0.004). There was significant linear correlation between dd-cfDNA levels and eGFR as shown in figure 1.



Conclusions: Our study found a significant correlation between baseline dd-cfDNA levels and decreasing eGFR. Higher levels of ongoing intra-graft inflammation and injury that could be associated with decreasing GFR is a plausible explanation for this finding. Decreased renal clearance of DNA fragments with declining GFR could also be contributory. These observations point towards the possible need for stratifying baseline dd-cfDNA based on the level of allograft function.

Abstract# 464

Single Cell RNA Sequencing of Tim1- B Cells and Tim1+ Regulatory B Cells

Q. Fu[1], K. Lee[2], K. Deng[2], D. Agarwal[3], P. v. Galen[4], C. G. Rickert[2], G. Huai[2], H. Yang[1], C. LeGuern[2], S. Deng[1], J. F. Markmann[2], *[1]Organ Transplantation Center, Sichuan Provincial People's Hospital, University of Electronic Sciences and Technology of China, Chengdu, China, [2]Center for Transplantation Sciences, MGH, Boston, MA, [3]Division of Transplantation, Department of Surgery, Hospital of the University of Pennsylvania, Philadelphia, PA, [4]Division of Hematology, Brigham and Women's Hospital, Boston, MA*

Purpose: Tim1 signaling has an important role in inducing and maintaining the function of Regulatory B cells. Our previous study showed that Tim1+ Bregs prolong the survival of islets in an allotransplantation model (Balb/c to C57BL/6). Here we examined the potential pathways and Breg subsets underlying TIM1+ Breg mediated regulation by RNA-seq and single-cell RNA-sequencing (scRNA-seq) analysis.

Methods: 30M Balb/c irradiated splenocytes were injected intraperitoneally into C57BL/6 recipients. After 14 days, Tim1- and Tim1+ cells were isolated for 10X Genomics 3' scRNA-seq analysis. The data was analyzed using Cell Ranger (version 3.1.0) and R programming (version: 3.6.3).

Results: Clustering of transcriptionally similar cells identified eight clusters of Tim1+ and Tim1- B cells (Figure 1a). The annotation results showed that Tim1- B cells were mainly included in cluster 0 (Klf2hiIglc1lo B cells), cluster 1 (Klf2hiIglc1hi B cells), and cluster 5 (Ifit3+ B cells). Immunology-relevant pathways were positively enriched in both clusters 0 and 5, suggesting that those cell populations were the main effector clusters of Tim1-B cells, potentially promoting allograft rejection (Figure 1b). Tim1+B cells were mainly included in cluster 2 (Klf2+Mifhi B cells), cluster 3 (Klf2+Cd21hi B cells), cluster 4 (Stmn1+Tim1+ Bregs), and cluster 6 (Cd106+Tim1+ B cells). Pathway enrichment analysis indicated that clusters 2 and 4 had similar enriched pathways, suggesting that clusters 2 and 4 were the primary immunosuppressive subset of Tim1+ Bregs (Figure). Cluster 7, mainly from Tim1+ Bregs, were identified as the plasma cells.

Conclusions: Subsets of Tim1+ and Tim1- B cells differ vastly in their gene expression, correlating with their roles during allogeneic transplantation. The ongoing analysis may illuminate key pathways that regulate the function of Klf2+Mifhi B cells and Stmn1+Tim1+ Bregs.

Kidney

Kidney Living Donor

Abstract# 469

The Australian and New Zealand Living Kidney Donor Profile Index

G. L. Irish[1], S. Chadban[1], N. Boudville[2], S. B. Campbell[3], J. Kanellis[4], P. A. Clayton[1], *[1]Australian and New Zealand Dialysis and Transplant Registry, South Australian Health and Medical Research Institute, Adelaide, Australia, [2]Medical School, University of Western Australia, Perth, Australia, [3]Department of Nephrology, Princess Alexandra Hospital, Brisbane, Australia, [4]Department of Nephrology, Monash Health, Melbourne, Australia*

Purpose: Risk scores may aid risk quantification and decision-making in kidney transplantation. The Living Kidney Donor Profile Index (LKDPI) was developed to choose between living donors. The original LKDPI is moderately discriminatory (Harrel's C Statistic=0.59,95% CI 0.55-0.61) but poorly calibrated in Australia/New Zealand. We developed a risk prediction score for overall graft survival in adult recipients of a living kidney donor transplant in an Australian and New Zealand population.

Methods: Using data from the Australia and New Zealand Dialysis and Transplant Registry, we included adult recipients of living kidney donor transplants over 2004-2018. We constructed Cox models for overall graft survival. We refit the original USA variables and then constructed a new model (ANZ LKDPI) considering all available potential covariates. Model performance was validated by assessing discrimination and calibration.

Results: 4049 living donors were included. The C-statistic for the re-fit model was 0.57(95%CI 0.54-0.59). The remodeled score included the new variables history of hypertension and HLA-A mismatches. Variables excluded were donor:recipient weight ratio, HLA-B, both male, and ABO incompatibility. The ANZ LKDPI had similar discrimination (C=0.56,95%CI 0.54-0.58). The model fit and calibration was better.

Conclusions: The ANZ LKDPI had similar discrimination to the original and the refitted LKDPI. The discrimination was low for both scores and so should be used with caution to decide between donors. The new score is better calibrated for our population so could be used to predict individual graft prognosis.

Abstract# 470

Recipient and Kidney Allograft Outcomes from Hypertensive Live-Donor in the United States

S. Riad[1], S. Jackson[2], D. Vock[3], A. Matas[4], *[1]Medicine, University of Minnesota, Minneapolis, MN, [2]Complex Care Analytics, M-Health Fairview, Minneapolis, MN, [3]School of Public Health, University of Minnesota, Minneapolis, MN, [4]Surgery, University of Minnesota, Minneapolis, MN*

Purpose: Controlled hypertension in select prospective kidney donors is no longer an exclusion criterion for donation. We examined the association between pre-donation hypertension (**HTN**) and both mortality and death censored kidney graft survival in recipients.

Methods: Between 2004 and 2019, we identified 2574 donors with **HTN** in the SRTR who had complete data for matching. Hypertensive donors were matched at 1:5 to normotensive donors, within the same transplant center, based on donor and recipient characteristics. Propensity matching was used to balance the cases and controls. All matching variables were evenly balanced between groups with SMD <0.05 (Table 1). 44 donors were not matched. Unweighted Kaplan-Meier curves were generated through 10 years from engraftment for the recipient survival (**RS**) and death-censored graft survival (**DCGS**) by donor hypertension status. Weighted Cox proportional hazard models (with each case-control group as a random effect) were used to examine the association between donor-**HTN** and outcomes of interest. In addition to the matching variables, models were adjusted for induction type, XM-status, HLA-MM, and immunosuppression maintenance. The RS model was stratified by transplant year, and the **DCGS** model was stratified by transplant year and immunosuppression maintenance due to non-proportional hazards.

Results: Hypertensive live-donor kidney utilization increased over time. **DGF** rate did not differ between groups. At 1-year from engraftment, eGFR was 2.3 mL/min lower (p=0.003), and the rejection rate was 1.5% higher (p=0.038) in the recipients of hypertensive donor kidneys. In the unweighted Kaplan-Meier analysis (Figure 1), **RS** did not differ by donor-**HTN** status (log-rank p=0.566). **DCGS** was slightly lower in recipients of hypertensive donor kidneys (log-rank p=0.025). In the multivariable weighted Cox PH models, compared to normotensive donors, kidneys from hypertensive donors were not associated with worse **RS** ($_{95\%LLCL}$ **aHR**$_{,95\%ULCL}$) ($_{0.93,}$**1.06**$_{,1.21}$), or **DCGS** ($_{0.99,}$ **1.16**$_{,1.36}$).

Conclusions: In this large propensity-matched cohort of live kidney donors and their recipients, donor hypertension was not associated with inferior recipient or graft survival after multivariable adjustment. The judicious utilization of kidneys from hypertensive donors in the United States appears safe for recipients. Expanding the donor pool with select hypertensive donors is a viable option.

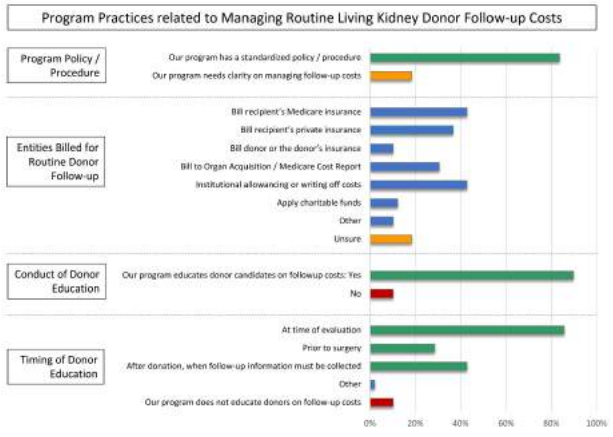
Abstract# 471

Managing the Costs of Routine Follow-up Care After Living Kidney Donation: A Survey of Contemporary Experience, Practice & Challenges

K. Lentine[1], G. McNatt[2], R. Howey[3], C. Thomas[2], R. Hays[4], U. Lebron-Banks[5], S. Ainapurapu[1], A. Tietjen[6], *[1]Saint Louis University, Saint Louis, MO, [2]Univ. Iowa, Iowa City, IA, [3]Toyon Associates, Concord, CA, [4]Univ. Wisconsin, Madison, WI, [5]New York-Presbyterian Hosp., New York, NY, [6]St. Barnabas, Livingston, NJ*

Purpose: Organ Procurement and Transplantation Network (OPTN) Policy mandates that living kidney donor (LKD) programs collect and report clinical and laboratory follow-up information for living organ donors at 6 months, 1 year and 2 years postdonation. Handling follow-up costs can pose challenges for programs and donors. To help inform the community and guide discussions of effective strategies for managing follow-up costs, we surveyed US LKD programs on current experiences and practices.
Methods: A brief 4-item survey instrument was designed by a multidisciplinary workgroup of professionals in transplant administration and LKD clinical care to assesses program policies, billing practices and donor candidate/donor education. We distributed the survey to staff at U.S. LKD transplant programs by email and posting to professional society list-servs in Fall 2020, using the Qualtrics survey platform in Fall 2020.
Results: Among 49 programs that participated to date, 84% have a standardized policy and procedure on how to handle the costs of routine follow-up. Mechanisms for recovering or covering the costs of mandated routine postdonation follow-up at responding programs include: billing recipients' Medicare (43%), billing recipients' private insurance (37%), institutional allowancing (43%), billing to organ acquisition or Medicare Cost Report (MCR) (31%), billing donors/donors' insurance (10%), and use of charitable funds (12%) (**Figure**). Although 90% of programs educate donor candidates on the costs and coverage of OPTN mandated follow-up, 10% do not. Provision of donor education most commonly occurs at the time of evaluation (89%), and 42% also educate at the time when follow-up must be conducted. 18% of programs are interested in more clarity on strategies for covering follow-up costs.



Conclusions: Based on a pilot survey of U.S. LKD programs, a variety of approaches are used to cover routine postdonation follow-up, ranging from billing recipients' or donors' insurance, to institutional allowancing or use of charitable funds, to inclusion on the MCR. Notably, although Medicare disallowed including these expenses on the MCR or billing the recipients' Medicare in 2016, these practices remain common, indicating a need for increased guidance. Up-to-date resources on handling the costs of routine donor follow-up will be useful for programs and living donors.

Abstract# 472

Compatible Paired Donation in Paired Kidney Exchange: A Look at the Road Not Taken

G. Vranic, A. Gilbert, B. Thomas, S. Ghasemian, M. Cooper, J. Verbesey, *MedStar Georgetown Transplant Institute, Washington, DC*

Purpose: Paired kidney exchange (PKE) offers incompatible donor-recipient pairs increased access to transplant. Compatible pairs are increasingly joining the PKE in an effort to find younger, better matched organs and altruistically to facilitate transplants by expanding the PKE pool. We reviewed compatible pairs entered into the National Kidney Registry (NKR) comparing the original donor entered into the exchange to the final donor the recipient received.
Methods: We conducted a retrospective cohort study of 17 compatible pairs transplanted via the NKR between 4/2017 and 11/2020 at a single center. For each pair a living kidney donor profile index (LKDPI) score was calculated. This has been used to characterize expected LD outcomes with a negative number predicting lower risk of allograft failure than any deceased donor organ and a number between 1 and 100 correlating with an expected risk of allograft failure comparable to the equivalent deceased donor KDPI.
Results: Recipients were more likely to be female (65%). Mean age was 43.8 years. All but one recipient was on dialysis at time of transplant. All recipients were ABO compatible with negative crossmatch and negative testing for donor specific antibody with their original donor. The PKE donors were younger (39.2 years) compared to original donors (44.6 years), p= 0.09. Five recipients got PKE donors older than their original donor while 12 received donors that were an average of 14.2 years younger. Mean creatinine clearance was higher for PKE donors (121 mL/min) compared to original donors (108 mL/min), p=0.05. One recipient with a left donor got a right kidney while two who had right donors received left kidneys. Five recipients who had donors with one artery received a donor with two arteries and two recipients with donors with two arteries got a donor with one artery. Average cold ischemia time (CIT) was 8.8 hours in this study vs expected 52 minutes for non-PKE living donor (LD) transplants.

Pair	Living Donor Recipient			Original Donor					PKE Donor					
	ABO	cPRA (%)	Age (yrs)	ABO	Age (yrs)	Lat	Art	LKDPI	ABO	Age (yrs)	Lat	Art	LKDPI	CIT (hrs)
1	A	0	43	O	38	Right	1	-15	A	35	Left	1	17	14
2	A	0	59	A	36	Left	1	35	A	56	Left	2	17	7
3	A	0	66	A	65	Left	1	59	A	49	Left	1	-3	13
4	B	0	35	B	34	Left	1	-9	B	28	Left	1	-4	6
5	O	2	51	O	47	Left	1	18	O	58	Left	2	18	8
6	A	75	43	O	22	Left	2	-11	A	32	Right	2	-9	1
7	O	0	51	O	31	Left	2	24	O	27	Left	1	-11	5
8	O	0	56	O	38	Left	1	26	O	29	Left	1	26	8
9	A	0	23	A	59	Left	1	35	A	37	Left	1	3	5
10	O	0	32	O	65	Left	1	14	O	43	Left	2	-13	8
11	O	100	73	O	38	Left	1	8	O	32	Left	1	1	20
12	O	92	34	O	43	Left	1	0	O	69	Left	1	46	4
13	O	54	46	O	38	Left	1	43	O	49	Left	2	-4	17
14	O	57	38	O	39	Right	1	-12	O	19	Left	1	-12	9
15	B	0	29	O	63	Left	1	45	B	37	Left	1	-19	9
16	O	0	28	O	56	Left	1	32	O	29	Left	2	-35	8
17	O	0	38	O	46	Left	2	6	O	37	Left	1	-2	7

All had immediate graft function. There was 100% graft and patient survival at 1 year. Mean serum creatinine levels were 1.2 mg/dL at 6 months (n=14) and 1.2 mg/dL at 12 months (n=12). LKDPI scores were better for PKE facilitated transplants on average (0.94 ± 19.1) compared to original donor-recipient pairs (17.5 ± 22.4), p=0.02.
Conclusions: Recipients enrolling into the NKR as compatible pairs receive organs from younger donors with better LKDPI scores. Centers can and should set limits on maximum acceptable donor age and prioritize low eplet mismatches for compatible pairs in the NKR to optimize LD recipient outcomes.

Abstract# 473

High Interest, Low Payoff: Understanding Opportunities for Intervention for Those Exploring but Not Pursuing Paired Kidney Donation

A. D. Waterman[1], E. H. Wood[1], A. Thomas[2], *[1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]Johns Hopkins, Baltimore, MD*

Purpose: In 2016, the National Kidney Registry (NKR) established an online donor screening portal (DASH) to manage and track individuals interested in kidney paired donation (KPD) through different stages of evaluation from indicating initial interest to actual donation. Potential donors generally interested in KPD or formally seeking evaluation through an individual NKR partner center enrolled in DASH. This study aims to describe progress through DASH evaluation stages and predictors of actual donation.

Methods: We included all individuals enrolled in DASH between 10/2016-10/10/2020, tracking their progress through 4 stages: Initial Contact, Clinical Questionnaire Screening, Online Medical History, and Actual Donation. Donors were removed from DASH for failure to proceed to the next stage within a specific time window (expired) or when clinical/psychosocial factors reported determined donor ineligibility (ruled out). We used multivariable logistic regression to identify predictors of donation among those who completed screening.

Results: NKR received 111,080 total contacts during the 4-year study period which translated into only 1,227 (1%) actual PKD donations (Figure). Among those that did donate, the median time from initial contact to actual donation was 206 days (IQR: 136, 307). Predictors positively associated with donation included having at least a college education (aOR 1.8, 95% CI: 1.4-2.3), private health insurance (aOR 2.1, 95% CI: 1.3-3.3), and being a spouse of the recipient (aOR: 1.6, 95% CI: 1.1-2.3). Predictors negatively associated with donation included being of African American race (aOR 0.5, 95% CI: 0.4-0.8), being a friend of the recipient (aOR: 0.3, 95% CI: 0.2-0.4), learning about PKD on social media (aOR: 0.1, 95% CI: 0.1-0.3), or having another relationship with the recipient (aOR: 0.5, 0.3, 0.7), history of high blood pressure, history of high cholesterol, history of obesity, and current tobacco use. The model AUC was 0.734.

Conclusions: While over 100,000 people expressed initial interest in pursuing PKD - enough individuals to solve the entire kidney donor shortage - few actually donated a kidney. With this high level of potential interest, if we can improve education and support of individuals who begin but fail to complete PKD evaluation stages, more PKDs might result.

Abstract# 474

Waitlist Outcomes for Patients with Hepatocellular Carcinoma Following the 2019 Exception Policy Change

K. Young[1], C. Enestvedt[2], W. Naugler[1], E. Maynard[2], A. Mitra[1], M. Wungiranirun[1], J. Jou[1], J. Ahn[1], M. Chang[1], D. Lhewa[1], *[1]Division of Gastroenterology and Hepatology, OHSU, Portland, OR, [2]Division of Abdominal Organ Transplant, OHSU, Portland, OR*

Purpose: We aim to compare waitlist (WL) outcomes for HCC patients after the implementation of the most recent UNOS exception policy change on 5/1/2019.

Methods: All U.S. adults (≥18yrs) listed for LT from 4/30/13-9/4/20 using the UNOS registry were evaluated. Patients were categorized based on date of listing into 3 eras - Era 1: 4/30/13-10/7/15, Era 2: 10/8/15-4/30/19 (6-month delay and a maximum 34 points), and Era 3: 5/1/19-9/4/20 (median MELD at transplant - 3). WL outcomes were evaluated with multivariate competing risk models, adjusted for demographics, UNOS region, ascites, hepatic encephalopathy (HE), biologic MELD, liver disease etiology, era, HCC, and exception status. In analyses stratified by era, follow up time was limited to end of that era.

Results: A total of 79,381 patients were listed for LT during the study period: 24,648 in Era 1, 39,536 in Era 2, and 15,197 in Era 3. The proportion of listed patients with HCC decreased from 25.7% in Era 1, 23.5% in Era 2, to 19.5% in Era 3. The proportion of HCC patients listed with exceptions also decreased from 74.0% in Era 1, 68.8% in Era 2, to 34.6% in Era 3. There was no significant difference in severity of ascites (p=0.06) or severity of HE (p=0.07) among HCC patients throughout the 3 eras. In Era 1, compared to non-HCC patients, HCC patients without exceptions (HR

1.30, p<0.001) and HCC patients with exceptions (HR 2.12, p<0.001) had a higher likelihood of LT. In Era 2, compared to non-HCC patients, HCC patients without exceptions (HR 1.10, p=0.003) and HCC patients with exception (HR 1.35, p<0.001) had a higher likelihood of LT. In Era 3, compared to non-HCC patients, HCC patients without exception had lower likelihood of LT (HR 0.90, p=0.04) while HCC patients with exceptions had a higher likelihood of LT (HR 1.60, p<0.001). In Era 1, HCC patients without exceptions had no significant difference in WL dropout/mortality compared to non-HCC patients, while HCC patients with exception had lower WL dropout/mortality (HR 0.82, p<0.001). In Era 2, HCC patients without exceptions had higher WL dropout/mortality (HR 1.30, p<0.001), while HCC patients with exceptions had no significant difference. In Era 3, HCC patients without exceptions continued to have higher WL dropout/mortality (HR 2.00, p<0.001) while HCC patients with exceptions had lower WL dropout/mortality (HR 0.35, p<0.001).

Conclusions: Patients with HCC MELD exception saw an overall decline in the likelihood of LT after the two most recent policy changes. However, the advantage for HCC patients with MELD exception still remains. There was no significant increase in the dropout/mortality on the WL for the HCC MELD exception patients, instead there was improvement after the 2019 changes which may be due to shorter follow up time. Overall, the changes reflect gradual move towards desired equity.

Abstract# 475

Severe Hypoxemia After Liver Transplantation in the Hepatopulmonary Syndrome

J. Doi, M. Fujiki, G. DAmico, K. Sasaki, T. Diago, F. Aucejo, C. Kwon, B. Eghtesad, K. Hashimoto, C. Miller, Q. Cristiano, *Cleveland Clinic, Cleveland, OH*

Purpose: Hepato-pulmonary syndrome (HPS) is a complication of liver disease with liver transplantation as the only curative treatment. However these patients can develop severe hypoxemia early after transplantation, defined as a need of 100% oxygen to maintain a saturation of >85 %. The data regarding the predictive factors or treatment for post-transplant severe hypoxemia and its impact on outcome is scarce.

Methods: Retrospective analysis of prospectively maintained database of 1862 patients who had liver transplants in our unit between 2007 and 2020, from which patients with a diagnosis of HPS were identified. Pre transplant variables related to HPS and postoperative oxygen requirement, duration of intubation, ICU stay, postoperative complications and survival data were collected.

Results: 51 (n=51) patients with HPS were identified during the study period. The median pre-transplant PaO2 on room air, diffusing capacity of the lung (DLCO), alveolar-arterial oxygen gradient (AaDo2), and intrapulmonary shunt ratio on radionuclide study were 55.3 mmHg, 49.0%, 59.0 mmHg and 18.0% (2.4 -47.8%), respectively. Postoperative severe hypoxemia occurred in 12 patients (24%). Among 12 patients, 2 patients was treated successfully by using extracorporeal membrane oxygenation (ECMO). Predictors of severe hypoxemia include intrapulmonary shunt ratio >20% and DLCO <40%. ICU stay, readmission rate and medical cost of the hospital stay were significantly higher in patients who developed severe hypoxemia than the others. Overall 1 and 3 years post-transplant survival of HPS patients were 84.3% and 82.4%.

Conclusions: Intrapulmonary shunt and DLCO predict the development of postoperative severe hypoxemia, which is associated with high morbidity and mortality. ECMO could be one of effective treatment for post-transplant severe hypoxia caused by HPS.

Abstract# 476

Long Term Survival After Liver Transplantation for Advanced, Unresectable Intrahepatic Cholangiocarcinoma

R. R. McMillan[1], S. Kodali[1], M. Javle[2], A. Saharia[1], C. M. Mobley[1], M. J. Hobeika[1], A. Shetty[1], D. W. Victor[1], R. McFadden[1], M. Abdelrahim[1], K. Heyne[1], A. O. Gaber[1], R. M. Ghobrial[1], *[1]Houston Methodist Hospital, Houston, TX, [2]MD Anderson Cancer Center, Houston, TX*

Purpose: Intrahepatic cholangiocarcinoma (ICCA) has traditionally been considered a contraindication to liver transplantation (LT). We previously reported a case series of six patients with large, unresectable ICCA tumors who underwent LT. A total of 17 patients have now undergone LT for ICCA at our institution. This study reports long term outcomes for these patients.

Methods: Retrospective review of a prospectively-maintained database was performed of patients undergoing LT for ICCA under an investigational protocol. Survival analysis was performed using the Kaplan-Meier method to report overall and recurrence-free survival.

Results: Seventeen patients underwent LT for ICCA. All patients had unresectable tumors and no extrahepatic disease. The study group underwent neoadjuvant therapy and maintained disease stability for more than six months. This patient population exhausted all therapeutic options and harbored tumor volume as great as 20 cm. Median follow up was 20.6 months. Five patients had cancer recurrence, and four patients died. Patient survival at 1-, 3- and 5-years was 100%, 80%, 60%. Recurrence-free survival at 1-, 3- and 5-years was 65%, 65%, and 32%. Sites of recurrence include the lung (n=2), bone (n=2), bowel (n=1), omentum (n=1), and brain (n=1). One patient had hepatic artery thrombosis and underwent a second LT.

Conclusions: Median survival for unresectable ICCA treated with systemic chemotherapy is less than 1 year. For patients with unresectable ICCA who undergo neoadjuvant therapy and demonstrate disease stability, LT offers an opportunity for long term survival. Additional research should identify factors prognostic for disease stability to inform patient selection.

Abstract# 477

Should We Curtail the Importance of Non-modifiable Risk Factors in Dcd Liver Risk Stratification?

R. Meier[1], Y. Kelly[2], S. Yamaguchi[2], H. Braun[2], T. Lunow-Luke[2], D. Adelmann[2], C. Niemann[2], D. Maluf[1], Z. Dietch[2], P. Stock[2], S. Kang[2], S. Feng[2], A. Posselt[2], J. Gardner[2], C. Freise[2], R. Hirose[2], C. Freise[2], N. Ascher[2], J. Roberts[2], G. Roll[2], *[1]University of Maryland, Baltimore, Baltimore, MD, [2]UCSF, San Francisco, CA*

Purpose: Scoring systems have been proposed to select donation after circulatory death (DCD) donors and recipients for liver transplantation (LT). We hypothesized that the generalizability of existing scoring systems is limited by distinct local factors such that conforming to a complex scoring system derived elsewhere may limit transplantation.

Methods: We used the University of California San Francisco (UCSF) data on DCD-LT (n=138) performed between 2003-2019 to calculate a UCSF-DCD risk score. This was validated using the United Network for Organ Sharing database (UNOS) (n=6,371). We compared the ability to predict graft survival of different scoring systems including United Kingdom (UK)-DCD-score, University of California Los Angeles (UCLA)-DCD-score, King's College Hospital score (KCH)-DCD-score and UCSF-DCD-score in both datasets.

Results: The strongest predictors in the UCSF cohort were donor functional warm ischemia time and donor hepatectomy time. A simple UCSF-DCD-score composed of just these two variables was able to stratify graft survival in our cohort and in the UNOS cohort (Figure). UK-, UCLA-, KCH-DCD-scores all successfully stratified graft survival in the UNOS cohort but failed to do so in the UCSF cohort. There was substantial variation in the ability of scoring systems to predict outcomes across UNOS regions. Based on the UK-DCD score, 43.5% of the DCD-LTs in the UCSF cohort were considered high-risk or futile. Specifically, 41.3% of recipients had a Model for End-Stage Liver Disease score>25 and 76.8% of LTs had cold ischemia

time>6h; on the other hand, donor mean age was 31 years old, i.e. 18 years younger than the UK cohort average. UCSF-DCD-score was the only score able to stratify the occurrence of biliary complications in our cohort.

Conclusions: Locally developed DCD scores failed to predict outcomes in our cohort, suggesting that extrapolation of locally derived DCD risk scores to other environments could limit transplantation. Additionally, the importance of non-modifiable factors should be minimized in DCD-scoring systems, and priority given to modifiable factors, such as donor warm ischemia and hepatectomy time.

Abstract# 478

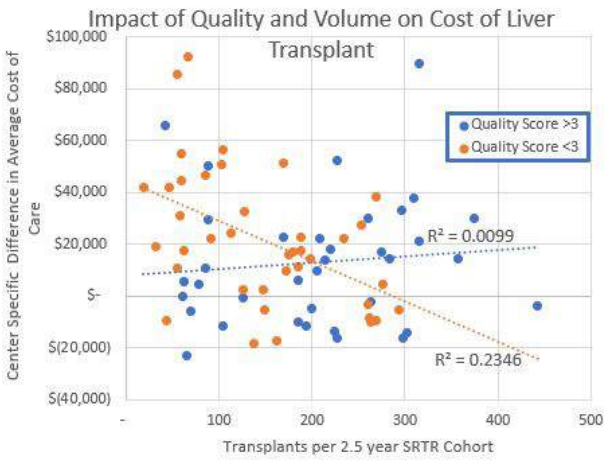
The Intersection of Cost, Quality, and Volume in Liver Transplant

D. Axelrod[1], R. Balakrishnan[1], A. Harris[2], S. Hohmann[2], J. Snyder[3], B. Kasiske[3], M. Schnitzler[4], K. Lentine[4], *[1]Univ of Iowa, Iowa City, IA, [2]Vizient Inc., Irving, TX, [3]SRTR, Minneapolis, MN, [4]Saint Louis Univ, Saint Louis, MO*

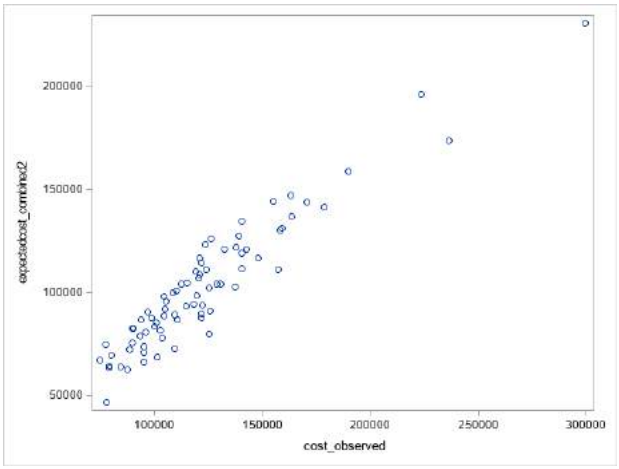
Purpose: As a consequence of changing allocation practices and the ongoing shortage of high-quality organs, the cost of liver transplant (LT) continues to increase throughout the United States. While previous analyses have examined the impact of recipient and donor factors, none have correlated pre- and post-transplant metrics, LT volume, and risk-adjusted cost of care.

Methods: A novel dataset was constructed linking Scientific Registry of Transplant Recipients (SRTR) transplant registry data, Vizient Clinical Data Base/Resource Manager, and program-specific reports. Multivariate fixed-effect linear regression models incorporating blinded center identifiers were used to estimate the risk-adjusted LT center cost differentials (betas). Quality was determined by dichotomizing centers on the basis of the sum of O:E ratios for 1-year patient survival, 1-year graft survival, transplant rate, and waitlist mortality (scale, 0-4).

Results: Clinical and cost data were examined for 7,381 LTs performed at 77 transplant programs from 2015 to 2018. Multivariate modelling was used to compare average observed and expected cost by center, demonstrating excellent correlation (Figure 1).



Centers with a quality score ≥3 were significantly less expensive ($P = 0.06$), without significant variation in cost by volume. Conversely, lower-quality centers were more expensive and revealed a strong inverse correlation between LT volume and average cost (Figure 2).



Conclusions: Accurate risk-adjusted LT costs can be derived combining administrative and registry data. Higher-quality centers are associated with lower risk-adjusted cost. Conversely, the impact of lower quality on cost is mitigated by LT volume. Increases in quality tend to remove the association between risk-adjusted cost and volume, demonstrating the benefit of developing reliable care processes.

Abstract# 465

Prevalence of Hepatitis E Virus Infection in Solid Organ Transplant Recipients: A Systematic Review and Meta-analysis

P. Hansrivijit[1], A. Trongtorsak[2], B. Boonpheng[3], C. Thongprayoon[4], W. Cheungpasitporn[4], *[1]Department of Internal Medicine, UPMC Pinnacle, Harrisburg, PA, [2]Department of Internal Medicine, Amita Health Saint Francis Hospital, Evanston, IL, [3]Division of Nephrology, David Geffen School of Medicine, University of California, Los Angeles, CA, [4]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN*

Purpose: Hepatitis E virus (HEV) infection is an underdiagnosed disease due to the use of serological assays with low sensitivity. Although most patients with HEV recover completely, HEV infection among patients with preexisting chronic liver disease and organ-transplant recipients on immunosuppressive therapy can result in in decompensated liver disease and death. The prevalence of HEV infection in solid organ transplant recipients is unknown and varies among organ types.

Methods: We searched Ovid MEDLINE, EMBASE, and the Cochrane Library for eligible articles through October 2020. The inclusion criteria are adult patients with history of solid organ transplantation. HEV infection is confirmed by either HEV-IgG, HEV-IgM, or HEV RNA assay.

Results: Of 563 citations, a total of 22 studies (n = 4,557) were included in the meta-analysis. The pooled estimated prevalence of HEV infection among solid organ transplant patients was 20.2% (95% CI 14.9-26.8). The pooled estimated prevalence of HEV infection in each organ transplant was as followed: liver (27.2%; 95% CI 20.0-35.8), kidney (12.8%; 95% CI 9.3-17.3), heart (12.8%; 95% CI 9.3-17.3), and lung (5.6%; 95% CI 1.6-17.9). The comparison across all organ transplant was statistically significant (Q = 16.721, p = 0.002). There was no statistical significance across subgroup analyses. The pooled estimated prevalence of de novo HEV infection was 5.1% (95% CI 2.6-9.6) and the pooled estimated prevalence of acute HEV infection was 4.3% (95% CI 1.9-9.4).

Conclusions: HEV infection is common in solid organ transplant recipients. The prevalence of HEV infection in lung transplant recipients is considerably less common than other organ transplants. More studies demonstrating the clinical impacts of HEV infection in solid organ transplant recipients, such as graft failure, rejection, and mortality, are warranted.

Abstract# 466

Belatacept for Kidney Transplantation in the Age of Covid19, is it Safe?

J. Pagan[1], S. Anjan[2], Y. Natori[3], A. Fernandez[3], R. Zamora-Gonzalez[2], A. Mattiazzi[1], L. Mendez[1], G. Guerra[1], *[1]Nephrology, University of Miami, Miami, FL, [2]Infectious Diseases, University of Miami, Miami, FL, [3]Infectious Disease, University of Miami, Miami, FL*

Purpose: The COVID19 pandemic has affected kidney transplant recipients (KTR) with a wide spectrum of clinical severity. Up to this point, we have solely seen reports describing outcomes of patients on calcineurin inhibitor-based regimens but there is a paucity of data regarding the use of belatacept (bela). Given the increased risk of viral infections seen with bela, this population is presumably at a higher risk for incidence and mortality of COVID19.

Methods: This is a single center retrospective study of Sars-Cov-2 PCR positive KTR between April and September 2020 who were on bela based regimens compared with tacrolimus (tacro) based regimens. The primary outcome was death or ICU admission at any time during the COVID19 infection. Secondary outcomes were rate of graft loss and rate of co-infection with bacterial, fungal or other viral pathogens.

Results: We identified 98 KTR who have been infected with Sars-Cov-2 of which 87 (84.4%) were on tacro and 11 (10.7%) were on bela. At our institution, currently there are 127 KTR on bela based maintenance immunosuppression; thus 11/127 (9%) developed COVID19. Mean age and gender was similar in both tacro and bela groups: (51 +/- 14 in tacro vs 57 +/- 12 in bela and 39% female in tacro vs 36% female in bela). Comorbidities (HTN, DM, COPD and HIV) were similar in both groups. Treatment was comparable and provided according to our current treatment protocols. Neither mortality (Figure 1) nor ICU admission was statistically significant between the groups (10% in tacro vs 9% in bela and 26% in tacro vs 27% in bela, respectively). Graft loss occurred in 5 (6%) of tacro patients and 1 (9%) of bela patients, not statistically significant. Co-infection with bacterial, fungal or viral pathogens in the tacro group occurred in 26 (30%), 8 (9%) and 5 (6%) of patients vs. 5 (45%), 1 (9%) and 0 patients in the bela group. These differences were not statistically significant.

Conclusions: Although limited with a small sample size and single center observations, the use of belatacept did not appear to worsen outcomes in terms of mortality, ICU admission, graft failure or rate of co- infections when compared to tacrolimus.

Abstract# 467

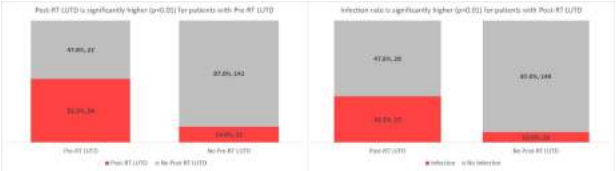
Pre-transplant Lower Urinary Tract Dysfunction in Men is a Risk Factor for Adverse Outcomes Following Renal Transplantation

M. J. Goldstein[1], B. R. Schleich[2], T. Carrea[1], Y. Yushkov[1], N. Cheng[3], R. Harrison[3], R. Munver[3], D. Fromer[3], *[1]Organ Transplant, Hackensack University Medical Center, Hackensack, NJ, [2]Patient Safety and Quality, Hackensack University Medical Center, Hackensack, NJ, [3]Urology, Hackensack University Medical Center, Hackensack, NJ*

Purpose: The expanding age criteria for candidacy for renal transplantation, in conjunction with prolonged waiting time for deceased donor kidneys has created new challenges for men with benign prostatic hyperplasia (BPH) and lower urinary tract dysfunction (LUTD). The prevalence of LUTD in the end-stage renal disease male population has not been well characterized. Furthermore, it is unclear how pre-transplantation LUTD should be treated and whether there is post-transplant benefit for risk reduction. Thus, the objective of this study is to characterize the prevalence of pre-transplant LUTD in male candidates for renal transplantation and its contribution to post-transplant outcomes.

Methods: A single center retrospective study investigated 208 male kidney recipients. We defined LUTD as meeting at least one of following criteria: frequency/urgency, obstructive symptoms, urinary retention, urinary incontinence or bladder outlet obstruction.

Results: 46 (22.1%) patients had pre-transplant LUTD. Patients with pre-transplant LUTD were four times more likely to experience post-transplant LUTD compared with patients without pre-transplant LUTD (52.2% vs. 13.0%; p<0.01). Patients with post-transplant voiding dysfunction were also over four times more likely to develop a urinary tract infection compared with patients without post-transplant voiding dysfunction (37.8% vs 8.6%; p<0.01). Furthermore, older patients are more likely to have post-transplant LUTD compared to younger patients (p<0.05). Diabetes, anuria/oliguria, and history of previous urinary infection did not significantly predict post-transplant LUTD in univariate analysis.



Conclusions: Pre-transplant LUTD is a significant predictor for development of post-transplant LUTD leading to higher risk of post-transplant urinary tract infection. Further study is warranted to investigate whether interventions to reduce pre-transplant LUTD or peri-transplant LUTD can reduce the incidence of urinary tract infections and complications after transplantation.

Abstract# 468

Impact of SARS-CoV 2 Infection on Graft Function in Kidney Transplant Recipients: An Academic Single Center Experience

S. Nahi, A. Shetty, S. Tanna, J. Leventhal, *Northwestern University, Chicago, IL*

Purpose: Kidney transplant recipients are a unique cohort in regard to SARS-CoV 2 susceptibility and clinical course, owing to their immunosuppressed state and propensity for kidney injury. The purpose of this study is to ascertain if, in kidney transplant recipients, SARS-CoV 2 infection impacts long term renal allograft function. Further, it also aims to identify prognostic indicators that accurately predict any impact on graft function.

Methods: This retrospective, single-center study included kidney transplant recipients with a positive SARS-CoV-2 PCR at Northwestern Memorial Hospital from January 1, 2020 to June 30, 2020. Fifty-three patients met the inclusion criteria. Each patient's clinical disease severity was ranked according to the WHO Ordinal Scale for SARS-CoV-2 Clinical Improvement, and the study population was divided into three groups based on disease severity {mild disease (ordinal scale of 0-2): n=11, moderate disease (ordinal scale of 3-4): n=29, severe disease (ordinal scale of 5-8): n=13). The primary endpoint was change in estimated GFR (eGFR) from baseline kidney function prior to the positive SARS-CoV 2 PCR to 90 days after the positive test. Relevant demographic and clinical data was also collected. A one-way ANOVA test was employed to compare the 3 groups, and a Welch's T-test assessed differences between sets of two cohorts.

Results: Change in eGFR from baseline kidney function prior to infection to 90 days after the first positive SARS-CoV 2 test was +1.76 %, -17.5 % and -23.16 % the mild, moderate and severe disease groups respectively (Figure 1). There was a significant decline in kidney function in the moderate and severe disease cohorts as compared to the mild disease cohort, with respective p values of p=0.0002 and p=0.021. Relative to the mild disease cohort, the moderate and severe disease cohorts also demonstrated significantly increased risk of developing AKI, both with p values of P=0.0001 (Figure 2).

Conclusions: Clinically severe SARS-CoV 2 infection is associated with greater risk of acute kidney injury and greater decline in renal allograft function at 90 days post infection, compared to mild disease. These results highlight the importance of closely monitoring renal allograft function, in kidney transplant patients with SARS-CoV 2 infection. Furthermore, there is a need for additional studies to determine longer term allograft outcomes.

Figure 1. Impact of increasing clinical SARS-CoV-2 disease severity on renal allograft function. (A) Incidence of AKI developed over course of clinical infection in each of the three patient cohorts, represented as a percentage of the cohort total. (B) In each clinical disease severity cohort, percent change in estimated GFR (eGFR) from baseline kidney function prior to the positive SARS-CoV 2 PCR to 90 days after the positive test.

Quality Assurance Process Improvement & Regulatory Issues

Abstract# 479

Video Virtual Transplant Evaluation and Listing

V. Casingal[1], B. Thrasher[2], J. Brown[2], C. Fotiadis[2], *[1]Department of Surgery, Atrium Health, Charlotte, NC, [2]Department of Transplant, Atrium Health, Charlotte, NC*

Purpose: Due to the COVID-19 pandemic, many hospitals suspended in person evaluations of kidney transplants during the March-April time period of 2020. State and local agencies accelerated approval for video virtual visits and retroactively approved for reimbursement parity with in person visits.The transplant center at Atrium Health (AH) moved quickly to a virtual platform to move patients along the kidney evaluation process. Providers used the doxy.me platform, and phone visits. The purpose of this QA project is to track access to transplant listing during a global pandemic.

Methods: Beginning on March 3rd, the transplant center at AH began a phased shut down (allowing emergency visits and surgeries only) in response to COVID-19. The re-entry process began in April and was in full effect beginning June 1 and continues in November. The "Covid Safe" kidney evaluation went from a 100% on site evaluation process to a hybrid process to include: virtual teaching, virtual nephrology visits, virtual financial and social worker. The on site component remained for surgical evaluations, and for those patients unable to complete the virtual platform. Evaluation and listing numbers are tracked as part of the ongoing QA process. We look to compare volumes from June-Aug 2019 vs. June-Aug 2020.

Results:

2019 vs. 2019 (July-Sept)		
	2019	2020
Total Nephrology visits	210	232
In person Nephrology visits	210	85
Virtual Nephrology visits	0	147
Referral to listing (days)	230	308
Percentage of ancillary visits Virtually	0	59%
Listed for Transplant	47	29
Transplant volume	33	34

In a short fashion, the transplant clinic was able to list patients evaluated on a virtual platform.

Conclusions: Kidney transplant evaluation can be performed in a hybrid fashion. During the COVID-19 pandemic we were able to continue to evaluate and list patients. We did see a delay in listing time, most likely due to the transition period required for teaching and appointment scheduling. Further follow up will focus on patient safety and outcomes, transplant rates, and patient satisfaction.

Abstract# 480

Transplant Trainee Education and Recruitment Experiences

D. E. Cassidy[1], A. E. Gomez-Rexode[1], J. R. Santos-Parker[1], M. S. Anderson[2], L. M. McElroy[3], M. E. Byrnes[2], S. A. Waits[2], V. S. Valbuena[2], *[1]University of Michigan Medical School, Ann Arbor, MI, [2]Department of Surgery, University of Michigan Health System, Ann Arbor, MI, [3]Department of Surgery, Duke University Medical Center, Durham, NC*

Purpose: The demand for training in abdominal transplantation has continued to decrease. General surgery residents have less exposure to transplant surgery, creating a need for intentional trainee engagement. There is limited knowledge to inform recruitment practices, thus we aimed to understand the training experiences of the rising transplant surgery workforce.

Methods: A 38 question survey was distributed to 324 trainee members of the ASTS about early exposure to transplant surgery and mentorship. Open-ended questions regarding career goals and recruitment experiences were included. Descriptive statistics were performed. Narrative responses were coded for content and reported thematically.

Results: 94 ASTS trainee members responded to the survey (29% response rate). 57% of participants had exposure to transplant surgery in medical school. This correlated with a higher interest level in the specialty at the beginning of residency (correlation = 1.19, $p<0.05$). Most trainees felt supported by transplant faculty during research time (64%) and their fellowship application cycle (73%). Narrative responses concurred with survey findings and identified three key themes: career aspirations, role models, and positive training experiences. Career aspirations included a desire for academic practice and work-life balance. Participants identified approachability and visible leadership as key attributes of role models. Positive early experiences included faculty mentorship and participation in transplant operations.

Conclusions: Early exposure to transplant surgery can optimize interest and recruitment in the specialty. Positive medical school experiences were common in the training narrative of participants. Participants reported having strong mentorship in the field, highlighting the importance of individual faculty mentorship practices to promote recruitment.

Themes		Theme (# of responses)	Example quotations
Career aspirations	Academic goals and focus on research	31	"Ultimately envision a career as an academic transplant surgeon with an NIH-funded research portfolio. I hope that my clinical activities and research will impact the field and push the field forward."
	Hepatobiliary practice	11	"After training, I envision myself as an academic surgeon who takes care of HPB focused patients by both means of resection and transplantation. Additionally, I see myself continuing as an outcomes researcher and in administrative roles."
	Technical skill	20	"I want to be capable of coping with the most difficult situations in the OR. I want to have a broad repertoire from minimally invasive procedures to open procedures."
	Importance of family and balance	14	"Academic transplant surgeon doing clinical outcomes research in transplant. Involved with ASTS and advancement of the field as a whole. Actively engaged in childcare/ involvement with children's education and activities."
Role models	Approachability and kindness	17	"Yes. There are two people that come to mind. I find them inspirational because although those field is very challenging they come into the OR with a joyful attitude. The nurses and staff are happy and great spirits because the surgeons have that effect."
	Visible leadership and technical skill	24	"Yes, there are a couple of individuals that are very inspiring. Their technical skill, patient centric management and devotion for teaching."
	Personal success at career balance	9	"Lots of people for different reasons. Admittedly I don't think there is one person who exemplifies exactly what I want my future career to be but many great leaders and examples. I very much appreciate people who are able to balance life and work, not that they are ever totally in balance but in a way that allows them to feel accomplished in both facets of their life."
Positive experiences in the specialty as a medical student and junior resident	Intentional mentorship	14	"The head of the department was very attentive towards us younger students, always keen to explain and listen." "All positive elements: direct patient care, mentorship from transplant faculty, research opportunities, sponsorship during residency applications, continued friendship after graduated from medical school."
	Meaningful patient care	9	"Amazing mentorship. Great opportunity to see positive changes in people's lives."
	Feeling part of a team	12	"Having mentors, residents and fellows who encouraged my interest and excitement and invited me to feel like a member of the team (going on donor runs, calling me in to scrub in on overnight cases, supporting medical student interest groups)."
	Opportunity for OR exposure	10	"Our program has a large service staffed with several 5-6 APPs on any given day. The APPs largely take care of the floor patients, and therefore the resident really has no responsibility other than to assist in the OR. For residents interested in transplant, many enjoy this structure."
	Increased level of responsibility	4	"We are given a lot of responsibility as junior residents on the transplant service. It's a difficult, busy service, but not the most work-intensive of our services as interns."

Abstract# 481

Assessing the Prevalence of Risk Factors for Osteoporosis and Rate of Screening by Dexa Scan in Patients Referred for Liver Transplant Evaluation

A. France[1], J. Kirk[2], M. Dokus[2], B. Al-Judaibi[2], M. Laryea[2], *[1]Department of Internal Medicine, University of Rochester Medical Center, Rochester, NY, [2]Division of Gastroenterology and Hepatology, University of Rochester Medical Center, Rochester, NY*

Purpose: Osteoporosis (OP) and fragility fractures are well-known complications of both chronic liver disease (CLD) and transplant, with a significant increase in the prevalence of fractures in months after liver transplant (LT). The objectives of this quality improvement project were to assess whether patients with CLD are appropriately screened for OP, to determine the prevalence of additional risk factors for bone loss in pre-LT patients and to ascertain whether systematic screening for low bone mineral density (BMD) should be a routine component of LT evaluation.

Methods: A retrospective chart review was performed of patients referred for LT evaluation at a large academic medical center from July 20 - November 5, 2020. Baseline characteristics including etiology of CLD, risk factors for OP, history of fractures and prior screening for low BMD with DEXA scans were reviewed. Assessment of nutritional and lifestyle risk factors was conducted by the transplant dietician.

Results: The median age for our population was 59 years; 48% of the population was female, and the most common reason for liver transplant evaluation referral was alcoholic cirrhosis. Of 84 patients referred for LT evaluation, 17 (20.2%) had a DEXA scan to screen for low BMD. Among the 17 patients with DEXA scans, 5 had osteopenia and 2 had OP. Three of those 7 were prescribed Vitamin D. Seventy-six patients (90%) had at least one risk factor for OP other than CLD. In the 47 patients that had 2 or more risk factors, 13 (28%) had a DEXA scan. The median MELD-Na score was 17. Of the 24 patients with MELD <15, 8 had a DEXA scan compared with 8/48 patients with MELD 15-25 and 1/12 patients with a MELD >25.

Conclusions: The low rate of screening for OP in this high risk population highlights a gap in the care of patients with advanced CLD. Even patients with multiple other risk factors for OP have a low rate of screening. Given the known impact of LT on bone density and the morbidity associated with fragility fractures, there is need for increased education about the risks of low BMD in patients with CLD at the primary care level, and BMD assessment should be a routine part of the transplant evaluation.

Table 1. Prevalence of OP Risk Factors	
Most prevalent risk factors for low BMD	***Number of patients (%)***
Age >50	57 (68%)
Current tobacco use	24 (29%)
BMI <21	12 (14%)
Excessive alcohol consumption	10 (12%)
Glucocorticoid use	7 (8%)
Prior fragility fracture	4 (5%)

Abstract# 482

Experiences of Women Trainees in Transplant Surgery

A. E. Gomez-Rexrode[1], D. E. Cassidy[1], M. S. Anderson[2], J. R. Santos-Parker[1], L. M. McElroy[3], S. A. Waits[2], V. S. Valbuena[2], *[1]University of Michigan Medical School, Ann Arbor, MI, [2]Department of Surgery, University of Michigan Health System, Ann Arbor, MI, [3]Department of Surgery, Duke University Medical Center, Durham, NC*

Purpose: To assess the unique experiences of women surgical trainees to better understand the recruitment and training strategies needed to ensure meaningful progress toward gender parity in the field of transplantation.
Methods: A 38-question survey was distributed to trainee members of the American Society of Transplant Surgeons (ASTS) to assess medical school and residency training experiences and exposure to transplant surgery, as well as career and academic mentorship received as trainees. Descriptive statistics and Mann-Whitney U tests were performed to determine statistical significance.
Results: Of the 324 ASTS trainee members contacted, 94 (29% response rate) completed the survey and 37% of participants identified as women. At the start of residency training, men rated their interest in transplant surgery significantly higher with a median score of 6.5 (6) compared to women (4.0 [6]) ($p<0.05$) on a rating scale of 1 = not interested, to 10 = very interested. At the start of their senior/chief years of training, both men and women rated their interest in transplant surgery equally (10 [1] and 10 [2] respectively). Most women (53%) and men (57%) senior residents had greater than one month of clinical exposure to transplant surgery at their home program and qualified their operative experience as excellent or good (94%; 76%). Most women and men trainees also felt supported by the transplant faculty at their institutions, both in their dedicated research time (68%; 63%) and during their fellowship application cycle (74%; 78%).
Conclusions: To date, a gender gap persists in transplant surgery. Women trainees report less interest in transplant surgery in their junior years and the survivorship bias from the cross-sectional study design may underestimate the magnitude of this finding. Although this difference is not reported in their senior years compared to their male counterparts, early career engagement of women trainees may provide an avenue to reduce the current gender gap. More organized and targeted mentorship, including supportive relationships with transplant surgeons early in trainees' careers and positive junior transplant surgery experiences, are needed to promote engagement in transplant surgery among women trainees.

Abstract# 483

Iatrogenic Sodium Exposure in Hospitalized Patients with Liver Disease

P. Klem[1], R. Mbangu Kot Mbau[2], B. Crowther[1], V. Lewis[1], S. Lin[1], E. Patrick[3], A. Nadrash[1], K. Schoeppler[1], I. Kim[1], *[1]Pharmacy, University of Colorado Hospital, Aurora, CO, [2]Pharmacy, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO, [3]Transplant Services, University of Colorado Hospital, Aurora, CO*

Purpose: Numerous medications administered in the hospital setting may contain hidden/additional amounts of sodium in the drug itself and via intravenous (IV) diluents or admixtures. In patients with liver disease, sodium from these non-dietary sources can worsen ascites/edema, volume overload, diuretic resistance and potentially prolong hospitalization.
Methods: To determine the frequency and extent of iatrogenic sodium overload, we evaluated patients with liver disease (defined as MELD score > 15) who were admitted to the inpatient hepatology service at University of Colorado Hospital with a dietary sodium restriction order between 1/1/18 to 1/1/20. We excluded patients who received normal saline or Lactated Ringers as IV volume expanding therapy or if they had a history of liver transplant. Our primary outcome was the amount of additional daily sodium intake from oral and IV medications and their associated diluents/admixtures during each hospitalization encounter.
Results: A total of 258 encounters from 201 patients were included in the analysis. The median daily sodium content from non-dietary sources was 96 mg (interquartile range, 0-573.85 mg). The most common admitting diagnoses were: alcoholic cirrhosis (15.5%) and hepatic failure with coma (8.1%). The average length of stay was 7 days. There were 111 encounters (43%) where patients received no additional sodium from medications. Of the remaining 147 encounters, patients from 94 encounters (36.4%), 20 encounters (7.8%), and 33 encounters (12.8%) received an additional average daily sodium between 1 mg to 1000 mg, > 1000 mg to 2000 mg, and > 2000 mg, respectively. The primary source of iatrogenic sodium intake was from IV antimicrobials and associated diluents/admixtures. The most common sources of iatrogenic sodium in patients with an average of > 1000 mg/day were IV vancomycin, ceftriaxone, piperacillin/tazobactam, metronidazole, and meropenem.
Conclusions: Our results indicate that iatrogenic sodium overload from medication sources is a frequent occurrence (20.6% of encounters received > 1000 mg of additional sodium from medications) in hospitalized patients with liver disease. Diligence should be taken to minimize use of very high sodium-containing antibiotics when appropriate and use lower sodium-containing infusion solutions. Future research is warranted to evaluate the impact of excess sodium on outcomes of patients on the liver transplant wait list.

Abstract# 484

Impact of the Covid-19 Pandemic on Transplant Pharmacist Workforce

J. Lyons[1], K. Khalil[2], J. J. Teuteberg[3], E. J. Henricksen[4], *[1]Department of Pharmacy, Loyola University Medical Center, Maywood, IL, [2]Department of Pharmacy, NYU Langone Health, New York, NY, [3]Medicine and Section of Heart Failure, Cardiac Transplant, and Mechanical Circulatory Support, Stanford University, Stanford, CA, [4]Department of Transplant, Stanford Health Care, Stanford, CA*

Purpose: Evaluate the impact of the COVID-19 pandemic on the transplant pharmacist workforce.
Methods: A voluntary survey open from August 18, 2020 to September 15, 2020 was sent out to two prominent solid organ transplant pharmacy listservs. Respondents were asked to give background about their transplant institution, patient population and departmental staffing. Respondents were asked to comment on how the COVID-19 pandemic has impacted their ability to perform their transplant related activities for patient care.
Results: A total of 67 transplant pharmacists from 57 centers responded to the survey. The majority (61.2%) of pharmacists surveyed practice primarily in abdominal transplant programs with 29.8% at small, 33.3% at moderate, and 36.8% at large volume centers (<100, 100-300, and >300 total transplants, respectively). Almost all institutions have a living donor kidney transplant program (96.5%) and in response to the COVID-19 pandemic, 55.2% of centers reported stopping non-life saving kidney and liver transplants, most (89.6%) stopped living donor transplants. A majority (73.1%) of pharmacists surveyed were funded by the pharmacy cost center. Due to the pandemic, 40% of centers surveyed stopped performing bedside medication education, and 46.3% no longer allowed caregivers on site for medication education (Figure 1). Consequently, 41.8% of the pharmacists surveyed felt that their confidence in their patients' understanding of medications decreased. Transplant pharmacists reported a perceived mean decrease in resources required for daily work responsibilities of 0.18% (IQR -0.35 - 0), 0.11% (IQR -0.3 - 0), and 0.26% (IQR -0.43 - 0) at

low, moderate, and high volume transplant centers, respectively; however, there was no statistical difference. The perceived mean decrease in resources for pharmacists who are under the pharmacy cost center (0.18%, IQR -0.35 - 0) compared to those who are not (0.12%, IQR -0.3 - 0) was also not significantly different.

Conclusions: There was a reported reduction in transplant pharmacist services due to the COVID-19 pandemic, particularly with patient education, and a perceived reduction in available resources, but no difference based on center volume. While life-saving transplant continued, the impact of patient education on outcomes remains uncertain.

Figure 1: Changes in Resources and Impact due to COVID-19 Pandemic (n = 67)

Resources and Education (n, %)	
Prior to COVID-19, how did you perform transplant medication education?	
Individual teaching sessions with patients and caregivers	65 (97)
Group teaching sessions with patients and caregivers	11 (16.4)
Pre-recorded teaching sessions with follow up	4 (6)
Please indicate how you feel about the amount of time/resources available to you and what is required for your daily work responsibilities (0-10)? mean (IQR)	6.9 (5 - 8)
Since the COVID-19 pandemic, please indicate how you feel about the amount of time/resources available to you and what is required for your daily work responsibilities, mean (IQR)	5.8 (4 - 7)
In response to the COVID-19 pandemic, my program made the following changes:	
Cancelled group teaching	15 (22.4)
Caregivers no longer allowed on site for education	31 (46.3)
Inability to provide in-person education at the bedside (e.g. Zoom, Webex, etc. education only)	27 (40.3)
Bedside pillbox fills no longer performed	11 (16.4)
No changes have been made	20 (29.9)
Other	14 (20.9)
Since implementation of post-transplant medication education changes, my confidence in patient and caregiver's level of understanding their medications has:	
Decreased	28 (41.8)
Not changed	36 (53.7)
Unknown	3 (4.5)
In response to the COVID-19 pandemic, my program made the following changes to transplant pharmacists' ability to see patients in the outpatient setting:	
Pharmacists no longer see patients in the outpatient setting	3 (4.5)
Pharmacists only see patients on an as needed basis in the outpatient setting	32 (47.8)
Pharmacists only conduct telehealth or phone call visits	27 (40.3)
No change	25 (37.3)
Not applicable; I do not work in the outpatient setting	4 (6)
Clinical and Financial Impact (n, %)	
In response to financial impact of the COVID-19 pandemic, my institution implemented the following changes:	
Additional time at work (overtime)	3 (4.5)
Reduction in hours (decrease in FTE)	10 (14.9)
Reduction in compensation	10 (14.9)
Termination of transplant pharmacists	0 (0)
Hiring freeze across the institution	35 (52.2)
No changes have been made	18 (26.9)
Other	23 (34.3)
Mandatory paid time off	5 (7.5)
Furlough	3 (4.5)
In response to the clinical impact of the COVID-19 pandemic, have you been asked to work in a different setting?	
Yes, I have been asked to work in a different clinical practice (e.g. ICU, medicine, etc.)	12 (17.9)
Yes, I have been asked to work in an operational setting	8 (11.9)
No changes	47 (70.1)

Abstract# 485

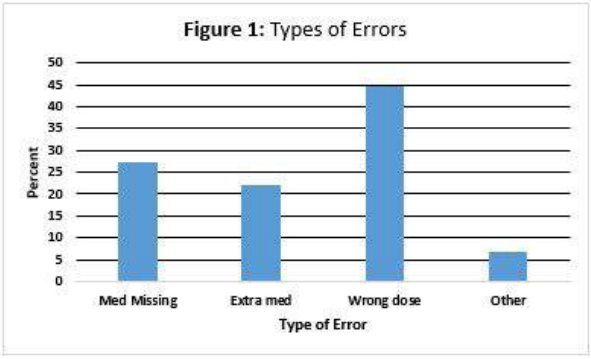
Reduction in Medication Errors at Discharge in the Transplant Population via Use of Novel Pharmacist / Nursing Dual Check System

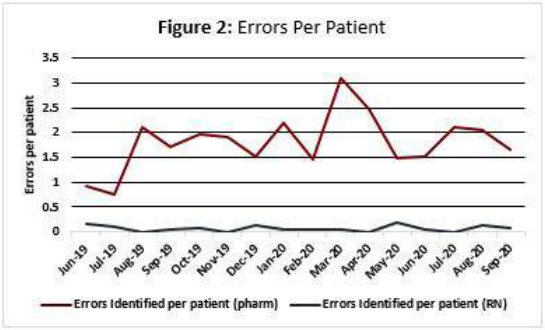
M. Norris, S. Witek, C. Whritenour, K. Sigafus, C. Chiang, C. Sammons, D. Naveiro, A. Paredes, E. Perez-Ngai, M. Kaminski, R. Westmoreland, G. Malat, *Hospital of the University of Pennsylvania, Philadelphia, PA*

Purpose: Medication errors are of great concern due to the risk for patient and allograft injury. The aim of this study was to evaluate the effectiveness of a novel multidisciplinary discharge medication reconciliation process.

Methods: Consecutive transplant recipients were retrospectively analyzed following the implementation of a multidisciplinary, quality improvement project targeting an efficient, effective discharge workflow. This project improved multidisciplinary communication and the discharge medication review process by including transplant pharmacist review prior to specialty pharmacy dispensing and nurse review after medication delivery. Data collected focused on quantifying the impact of the reduction of medication errors at discharge.

Results: Seven-hundred twenty-three total medication errors were captured, among all adult abdominal organ recipients transplanted between Jun 1, 2019 and Sep 1, 2020 (N=389). The majority of errors were identified prior to medication dispensing (96%), with a median of 1.8 errors per patient (IQR 1.5-2.1). Types of error are described in Figure 1. The highest errors per patient identified were in March (3.2) and April (2.5), 2020 (Figure 2). Adherence to novel discharge workflow improved from 59% to 100% throughout the study period by pharmacy and nursing staff.





Conclusions: A novel discharge workflow incorporating transplant pharmacists, nursing, and specialty pharmacy staff was effective in detecting and mitigating medication errors at each step in discharge process, improving discharge efficiency and de novo abdominal transplant recipients transitions of care.

Abstract# 486

Review of Unos Report of Organ Offers is Supplemented with Documented Real-time Communication Messages

E. S. Pahl[1], N. Patterson[2], *[1]University of Iowa, Iowa City, IA, [2]Iowa Methodist, Des Moines, IA*

Purpose: Use real time group messaging data among procurement and transplant professionals to supplement the review of UNOS Report of Organ Offers (ROO) for declined primary offers when the organ was later transplanted elsewhere at a later sequence.

Methods: UNOS ROO data for offers facilitated by an organ procurement organization (OPO) from July 2017 - December 2020 were connected to group messaging data from a dedicated secure communication mobile app used by participants from the OPO, recovery, and transplant clinical and coordination teams. Critical decision time points in the organ offer, procurement, and transplant processes were reviewed on a monthly basis during a routine monthly meeting among the teams.

Results: Teams reported enhanced quality of their monthly retrospective review of the ROO when supplemented with real time documentation. Administrators reported that they received a detailed, factual account of what transpired during each offer. Teams highlighted that having real time documentation was particularly useful for organ offers that were later transplanted elsewhere at a later sequence. Administrators substantiated the need for centerwide organ acceptance standards and processes. The delineation resulted in increased buyin from clinical teams.

Conclusions: UNOS ROO and other organ utilization tools and data are used to effectively improve offer evaluation processes in organ procurement and transplantation. Mobile apps capture additional contextual data that is helpful when analyzing

offer data and mitigate reimbursement and liability issues. Reviewing insights provides an opportunity for feedback and testing of decision-making strategies and organ offer filters.

Table. Report of Organ Offers with color code Green: transplanted, Gray: never primary, Orange: transplanted someone else same center, and Red: transplanted elsewhere after the decline. Particularly for Red offers, programs look at data captured in the real-time messaging app to reconstruct the case events and timeline.

Figure. An organ case using the mobile application, which automatically records and documents context, coordination, and communication events and is linked to supplement any organ offer from the UNOS report of organ offers.

Organ	Offer Sequence	KDPI	EPTS	Initial Offer Acceptance	Distance	Primary	Transplanted	Declined

Abstract# 487

Tacrolimus Shortage and the Rush to Convert: An Unexpected Burden on the System During the Covid-19 Pandemic?

N. Pilch, L. Johnson, M. Aldoughaim, N. Patel, F. Bartlett, *Medical University of South Carolina, Charleston, SC*

Purpose: A national shortage of immediate release (IR) tacrolimus (FK) fully impacted our center in May 2020. The conversion process was immediately challenging during the peak of the COVID-19 pandemic in our state. The aim of this analysis was to assess the healthcare burden that resulted from a national IRFK shortage.

Methods: This is a retrospective analysis of the conversion from IRFK to tacrolimus XR for all adult kidney recipients transplanted during the 2019 calendar year who had a functioning graft at the start of conversion (May 2020). Pts were divided into converted and not converted cohorts. Health care resource utilization as evidenced by notes in the EHR and encounters for therapeutic drug monitoring (TDM) were captured for 180 days for all pts; for converted pts these data were collected pre and post-conversion. The avg salary for a RN coord is $75K/yr or $38.46/hr. For each EHR encounter the average est cost was 30 mins ($19.23) and TDM was 15 mins ($9.62). Est PharmD costs per 17$/15 mins based on average base salary of $150K and a phone call time was est at 10 mins/call, provider costs estimated on avg base salary $75/hr consider 30 mins, $37.50 required for conversion and education for single post-conversion visit that would not have been required if conversion were not necessary.

Results: 226 pts were transplanted in 2019 with 113 pts included for analysis (Figure 1). Pts without conversion had less EHR encounters during the study period (Table 1). TDM did not differ significantly pre and post-conversion among groups but did between groups. For the converted cohort total provider estimated costs was $3187.50 however if this were expanded to the estimated 2000 patients currently in follow-up the cost of provider time for conversion would be estimated around $75K. PharmD fielded an average of 10-15 calls/day (150 mins/day) for 6 wks following the initial conversion period for all patients. The cost for this time period was estimated at $4500.

Conclusions: Converted pts overall had more healthcare encounters and TDM encounters pre and post-conversion compared to those that were not converted. Additional provider, coordinator and PharmD time were required for conversion efforts.

Table 1: No Conversion versus Conversion Resource Utilization Estimates

	No Conversion n=28	Conversion n=85
Electronic health record encounters 90 days before (#, avg±SD)	6±4	10±8
Cost of electronic health record encounters 90 days before ($, avg±SD)	115±76	201±150
Therapeutic drug monitoring encounters 90 days before (#, avg±SD)	2±2	2±2
Cost of TDMencounters 90 days before ($, avg±SD)	23±15	22±17
Electronic health record encounters 90 days AFTER (#, avg±SD)	7±5	12±6
Cost of electronic health record encounters 90 days AFTER ($, avg±SD)	134±93	222±118
Therapeutic drug monitoring encounters 90 days AFTER (#, avg±SD)	2±3	3±2
Cost of TDMencounters 90 days before ($, avg±SD)	22±26	27±16

Abstract# 488

Clinical Impact of Transplant Pharmacists on the Care of Solid Organ Transplant Recipients

I. Shah[1], J. Au[1], A. Diamond[1], N. Sifontis[2], C. Ruggia-Check[1], *[1]Temple University Hospital, Philadelphia, PA, [2]Temple School of Pharmacy, Philadelphia, PA*

Purpose: The United Network for Organ Sharing (UNOS) and Centers for Medicare and Medicaid Services (CMS) requires transplant centers to document the participation of a clinical pharmacist on multidisciplinary solid organ transplant (SOT) teams. These pharmacists are integral in providing and supporting evidence-based practices, quality improvement initiatives, medication access, patient education and protocol development. The purpose of this study is to evaluate the impact of SOT pharmacists on the care of SOT recipients.

Methods: This prospective, quality improvement, chart review included all patients who received a SOT and had at least one clinical intervention documented by the transplant pharmacist (3 full-time pharmacists and 1 SOT resident). The primary

objective of the study was to determine the impact of the transplant pharmacy team in identifying and correcting medication errors pertaining to immunosuppression, rejection, and infection (antiviral, antifungal and PJP prophylaxis and treatment). The secondary objectives were to quantify the acceptance rate of the interventions, estimate financial impact of the interventions made, and quantify the time commitment to optimize medication regimens.

Results: A total of 210 patients were included in the study from July 1 to November 9, 2020. Transplant pharmacists documented 1,380 interventions in the three-month period with an acceptance rate of 95%. The most common type of transplant with documented interventions was lung (59%) followed by kidney (16.2%), heart (11.9%), liver (8.1%), heart-kidney (1.9%), kidney-pancreas (1.4%), heart-lung (1%) and liver-kidney (0.5%).The most common intervention categories were dosing issues (69.9%) followed by appropriate therapy (20.1%). A breakdown of types of interventions within these categories is located in the table below. The median number of interventions per patient was four [IQR: 1-9]. The total time spent making clinical interventions was 8,139 minutes. Through the clinical interventions recommended by transplant pharmacists, the estimated cost-avoidance was $319,787.

Key intervention categories		
Intervention type	Immunosuppression	Infection and rejection
Kinetic dose adjustment	539	0
Renal dose adjustment	1	115
Dosing adjustment (other)	119	32
Additional drug required	113	107
Drug-drug interaction	8	5
IV to PO	44	47

Conclusions: Transplant pharmacists play an integral role in SOT multidisciplinary teams to optimize patient care through identification and correction of medication errors related to immunosuppression, infection, and rejection. Interpretation of these results may be limited by inter-pharmacist variability in documentation. Appropriate identification and correction of medication errors is associated with significant cost-avoidance.

Abstract# 489

Proxies of Ischemia Time Do Not Predict 1-Year Posttransplant Survival

M. Skeans[1], A. Wey[1], E. Lease[2], C. Lehr[3], J. Alcorn[4], R. Goff[4], D. Stewart[4], M. Valapour[3], *[1]SRTR, Minneapolis, MN, [2]Univ of Washington, Seattle, WA, [3]Cleveland Clinic, Cleveland, OH, [4]UNOS, Richmond, VA*

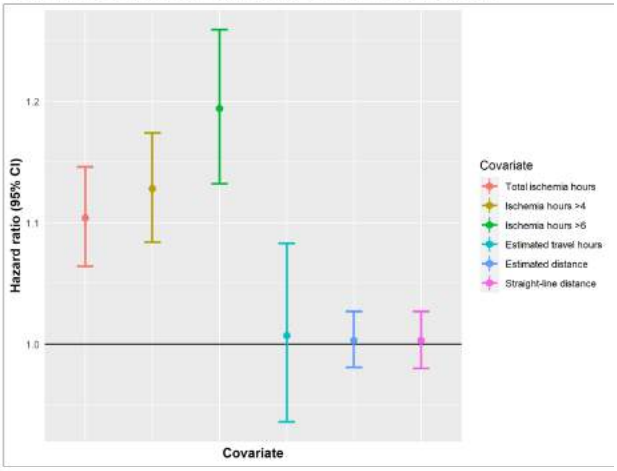
Purpose: A barrier to broader distribution of donor organs is a concern that increased donor-to-recipient (DtR) distances could increase ischemia times and compromise posttransplant (PT) survival. Some experts have recommended using DtR travel distance or time as proxies for ischemia time in a PT survival component of a continuous allocation score.

Methods: We estimated DtR travel time and distance for lung transplant recipients from January 1, 2015 to December 31, 2018, using a Google application programming interface. We fit 6 Cox proportional hazards models to estimate the effects of ischemia time and its proxies (distance and time) on 1-year PT survival. Each model included the same donor and recipient factors, plus one of the following: ischemia time, ischemia time splines with knots at 4 or 6 hours, travel time, travel distance, or straight-line distance. We computed the correlation of ischemia time with its linear proxies.

Results: Ischemia time was a significant predictor of PT survival, but none of its proxies were. Risk of PT death increased 10% for each increased hour of ischemia time. Linear splines resulted in 13% and 19% increases in risk of PT death for each additional hour of ischemia time above 4 and 6 hours, respectively. These estimates were significant at the $P<0.0001$ level. Hazard ratios for the three proxies were no different from 1 (Figure). While the proxies were significantly correlated with ischemia time ($P<0.0001$), the percent of variability explained (the square of the correlation coefficient) ranged from 17.0% for straight-line distance to 19.4% for travel hours. Thus, over 80% of the variability in ischemia time was due to factors other than travel. Clinicians theorized that travel and operating room (OR) logistics, OR complications, difficult donors, and complicated recipients contribute to ischemia time.

Conclusions: Ischemia time was correlated with DtR travel time and distance but not strongly enough to predict outcomes. Non-travel factors may explain the relationship between ischemia time and PT survival.

Figure 1: Effect of ischemia time and proxies on 1-year PT survival



Note: Estimated and straight-line distances are modeled per 100 miles; hazard ratio represents increased risk of 1-year death per 100 mile distance increase.

Abstract# 490

Aligning Pediatric Waiting List and Post-Transplant Outcomes with the Adult Lung Allocation Score

M. Skeans[1], A. Wey[1], E. Lease[2], C. Lehr[3], J. Alcorn[4], R. Goff[4], D. Stewart[4], M. Valapour[3], *[1]SRTR, Minneapolis, MN, [2]Univ of Washington, Seattle, WA, [3]Cleveland Clinic, Cleveland, OH, [4]UNOS, Richmond, VA*

Purpose: Lung allocation is moving toward a continuous distribution framework (CDF), with components for waitlist (WL) urgency and post-transplant (PT) survival, as computed in LAS. Candidates aged 0-11 years are excluded from LAS models and classified as Priority I (more urgent) or II. We computed expected WL and PT survival in this cohort to be used in the CDF to align with candidates aged ≥12 years who receive a lung allocation score (LAS).

Methods: We estimated predicted number of WL survival days within a year (WLAUC) and predicted number of PT survival days within a year (PTAUC) for Priority I and II candidates. Model cohorts included candidates and recipients aged 0-11 years from September 12, 2010 to January 31, 2019. WL follow-up was censored on the earliest of 1 year after joining the cohort; removal from the WL; January 31, 2020; or the candidate's 12th birthday. Outcome was 1-year WL survival. PT follow-up was censored at 1-year PT. Outcome was 1-year PT survival. We fit Cox proportional hazards models, each with one covariate: Priority I vs. II. Each model generated a baseline survival function and an estimate associated with Priority I. From these, we computed the WLAUC and PTAUC for Priority I and II. We computed LAS(p) as a function of WLAUC and PTAUC, similar to LAS.

Results: The WL cohort included 271 candidates, 54 (19.9%) of whom died waiting. Among 136 recipients, 51 (18.8%) died within 1 PT year. About half of patients (49.1%) were Priority I at cohort entry, and 58.1% were Priority I at transplant. Priority I was a risk factor for 1-year WL death but not 1-year PT death (Figure). Priority I and II patients were predicted to live 247 and 325 days, respectively, on the WL and 333 and 328 days PT. Priority I and II patients had effective median LAS(p) of 52.0 and 37.3, respectively (Table).

Conclusions: Pediatric Priority can be aligned with LAS to allow pediatric patients to receive points for WL urgency and PT survival in a CDF. Pediatric priority is associated with WL mortality but not PT mortality.

Table 1: Estimates of survival days by Pediatric Priority score

	N	WLAUC (days)	PTAUC (days)	LAS(p)
Priority I	133	247	333	52.0
Priority II	138	325	328	37.3
Overall	271	286	331	44.5

Fig 1: Effect of Pediatric Priority I vs. II on waitlist and posttransplant survival

Abstract# 491

The Implementation of the New Unos Policy That Relegates C-peptide and Body Mass Index Criteria Has Resulted in Shifting Recipient Demographics

R. Teo, A. Rechnitzer, N. A. Muhdi, J. Torabi, M. Ajaimy, L. Liriano-Ward, Y. Azzi, C. Pynadath, P. Loarte-Campos, A. Brooks, J. P. Rocca, M. Le, E. Akalin, J. A. Graham, *Montefiore Medical Center, Bronx, NY*

Purpose: Waitlist time accrual for SPK was previously limited to candidates on insulin that had either a c-peptide ≤ 2 ng/ml, or a c-peptide > 2 ng/ml and a body mass index (BMI) ≤ 30 kg/m^2. As of July 11, 2019, these requirements were removed from the UNOS Pancreas Transplantation Committee Policy 11.3.B. The effect of this policy change on recipient demographics and outcomes has not been studied.
Methods: An analysis of 76 SPK transplantations at Montefiore Medical Center from June 2014 to October 2020 was performed. SPK recipients pre- and post-policy change were compared. Endpoints included post-operative graft function and complications.
Results: There were 51 SPK recipients before and 25 recipients after the policy change. There was a significant increase in the average age (38.9 v 46.2 years, p = .01), BMI (25.5 v 27.5 kg/m^2, p = .03), and c-peptide levels (1.7 v 4.5 ng/ml, p = .01) following the removal of BMI and c-peptide requirements. There were no significant differences in outcomes or rates of complications.
Conclusions: The modification to the current policy expanded potential recipient demographic criteria while maintaining suitable outcomes. Our single center experience reflects the intended consequences of the adoption of the UNOS Pancreas Transplantation Committee Policy 11.3.B. This may prove to be beneficial for disadvantaged populations.

Abstract# 492

Frailty and Short-Term Outcomes in Kidney Transplant

S. Van Arsdale[1], K. Torbert[1], R. Harland[2], A. Turner[2], B. Tanriover[3], V. Ariyamuthu[3], *[1]Banner University Medical Center, Tucson, AZ, [2]Surgery, Banner University Medical Center, Tucson, AZ, [3]Internal Medicine, Banner University Medical Center, Tucson, AZ*

Purpose: Studies suggest worse outcomes for frail solid organ transplant recipients. We analyzed post transplant outcomes in relation to frailty.
Methods: We conducted a retrospective study of 476 kidney transplant recipients from 1/1/2016-8/10/2020. Frailty was assessed using handgrip, physical inactivity, gait speed, weight loss and exhaustion. Scores as outlined in the fried frailty phenotype (FFP) assessment, 0 = not frail, 1-2 = pre-frail, 3-5 = frail. This cohort included pre-FFP tested recipients (no frailty testing) n = 325 and post-FFP tested (implementation of FFP testing) recipients n = 151. Changes in delayed graft function (DGF), length of stay (LOS), and 30-day readmission as primary outcomes pre- and post-implementation of FFP testing were analyzed. Logistic regression models were fitted to estimate the odds ratios of primary outcomes. Multivariable logistic regression was adjusted for age, gender, race, dialysis duration, diabetes, BMI, donor type (living vs deceased), cPRA, and previous transplant. P values < 0.05 were considered statistically significant.
Results: The DGF rate significantly decreased from 44.3% to 29.8% post-FFP (OR 0.50, CI 95%: 0.32-0.78, P=0.003) compared to pre-FFP era. There was no significant change for LOS (52.9% vs 51.0%, p=0.70) (OR 1.10, 95%CI 0.72-1.67), but an increase in the 30-day readmission rate (32.4% vs 45.0%, p=0.01) (OR 170, 95%CI 1.13-2.56) post-FFP assessment.
Conclusions: A significant association between frailty assessment and reduction in DGF rate was demonstrated. Use of frailty assessments in pre-transplant patient selection may be beneficial in reducing post-operative short-term outcomes.

Abstract# 493

Single Day Centralized Approach in Kidney Transplant Workup - Lessons Learned from 2 Centers

A. Vijay, N. Langford, K. Atiemo, S. Giusti, M. Killackey, A. Paramesh, H. Jeon, *Tulane Abdominal Transplant Institute, New Orleans, LA*

Purpose: Time from transplant evaluation to UNOS listing is unaccounted towards wait-list time in pre-dialysis patients and hence longer evaluation to listing times can prolong the transplant candidate's time on dialysis. In the past, centers have reported a reduction in time to listing by implementing a 1-day center-coordinated pre-transplant workup. However these studies are single center studies that have compared listing times before and after adopting a one day workup approach. Such studies may have limitations due to comparing patients in different eras and may not have accounted for the changes in transplant staff nor changes in minimal listing criteria during the different study periods.
Methods: 310 patients were evaluated for Kidney transplant candidacy at 2 centers operated under a common university-based hospital from July 1, 2019 to July 1, 2020. Single day centralized work-up was used at one center which coordinated necessary tests needed to fulfill minimum listing criteria (same day echo, stress test, ultrasound, ct scan, PFTs, labs, CXR, EKG). This was compared with the conventional evaluation center (same-day labs, CXR, EKG with remaining tests individually scheduled after the initial visit). Staff resources at both centers were the same (Transplant surgeons, physicians, coordinators). Time from referral to UNOS listing and evaluation to UNOS listing were compared between the two groups.
Results: Of the 310 patients analyzed, 72 underwent 1-day center-coordinated evaluation and 238 underwent conventional evaluation. 27 patients at 1 day center and 87 patients at conventional center were deemed not candidate for transplant and were excluded from the study. The median time from referral to evaluation was slightly higher in the 1-day center, 77days vs 69 days in conventional center. The median time from evaluation to being presented at selection meeting was slightly higher in the conventional center group (125 days vs 121 days). The 1-day center had a slightly lower median time from evaluation to UNOS listing (154 days vs 165 days).
Conclusions: We did not find a significant decrease in time to listing for kidney transplant in spite of incorporating a 1-day center-coordinated pre-transplant workup. We believe that prioritizing staff resources is paramount to optimizing the advantages of a single day centralized pre-transplant kidney workup. Channeling selected patients (pre-dialysis, recipients with potential living donors, high pra, or many years of dialysis behind them) who might benefit from a decreased time to waitlist into a 1-day pretransplant workup center may make more meaningful resource utilization.

Abstract# 494

Creating Efficiency in the Kidney Transplant Listing: Can We Streamline Candidate Ineligibility?

A. Vijay, N. Langford, K. Atiemo, S. Giusti, M. Killackey, H. Jeon, A. S. Paramesh, *Tulane Abdominal Transplant Institute, New Orleans, LA*

Purpose: Evaluation of multiple transplant candidate referrals is a resource-intensive process that may delay listing and eventually transplanting appropriate patients. In this study, we sought to streamline ineligibility criteria at a single transplant center as a quality improvement initiative to make the transplant listing process more efficient.

Methods: We evaluated all patients referred to our center for kidney transplants between July 1, 2019, and July 1, 2020. All patients underwent testing consistent with UNOS established minimum listing criteria and were presented at a multidisciplinary transplant selection committee. We analyzed and grouped specific reasons for transplant ineligibility among those patients who were declined for transplant listing.

Results: Three hundred and ten patients were referred and evaluated for kidney transplant candidacy. Of these, 110 patients (35%) were declined for transplant listing. Medical comorbidities were the reason for ineligibility in 55 (50%) patients (including poor functional status in 32 pts., cardiac disease 10 pts., peripheral vascular disease 6 pts., morbid obesity 4 pts., malignancy 3 pts). Fifty-four patients (49%) were ineligible due to psychosocial concerns (non-compliance 28 pts, travel/family support issues 14 pts., legal issues 10 pts., financial issues 2 pts.). One patient had improvement in kidney function during the evaluation process and no longer qualified for transplant.

Conclusions: Pre-transplant evaluation is very resource intensive for transplant centers. Detailing and understanding the reasons for ineligibility among referrals may help transplant centers streamline their evaluation processes to identify and list the right patients efficiently for transplant. This is an important quality initiative that every transplant center must consider.

Abstract# 495

Value of a Personal Systems Approach in Improving Medication Adherence in Adult Kidney Transplant Patients: A Cost-effectiveness Analysis of the MAGIC Randomized Clinical Trial

M. R. Wakefield[1], M. Whittington[2], C. Ashbaugh[3], L. M. Remy[4], D. Aholt[4], C. Miller[4], D. Hathaway[5], D. Clark[5], K. Goggin[5], R. J. Ellis[6], C. L. Russell[4], *[1]Surgery/Urology, University of Missouri School of Medicine, Columbia, MO, [2]University of Kansas Medical Center, Kansas City, KS, [3]University of Missouri Health Care, Columbia, MO, [4]University of Missouri-Kansas City, Kansas City, MO, [5]Children's Mercy Kansas City, Kansas City, MO, [6]Indiana University School of Nursing, Indianapolis, IN*

Purpose: The objective of this evaluation was to estimate the cost of implementation and the cost-effectiveness of a person-level intervention called SystemCHANGE™.

Methods: To estimate the intervention costs, a direct measure micro-costing approach was used following key informant interviews with project champions and a review of implementation expenditures. Cost-effectiveness was calculated by comparing the incremental implementation costs and healthcare costs associated with non-adherence to the incremental percent adherent, defined as the percent of patients who took greater or equal to 85% of their medication doses, for each pairwise comparison.

Results: Medication adherence was improved at 6 months for the SystemCHANGE™ intervention (median 0.91, IQR 0.76-0.96) compared to attention control (median 0.67, IQR 0.52-0.72) with a marked difference in medians (0.24, 95% CI 0.13-0.30, $P < .001$). The intervention was low-resource to implement, costing approximately $520 to implement per patient, and was associated with significant improvements in medication adherence.

Conclusions: Interventions to improve medication non-adherence in transplantation have recently moved from a focus on motivation and intention, to a focus on person-level quality improvement strategies to link adherence to established daily routines, environmental cues and supportive people. In this study, the implementation costs were more than outweighed by the expected healthcare savings associated with improvements in adherence. This person-level intervention is a low cost, efficacious intervention associated with significant statistical and clinical improvements in medication adherence in adult kidney transplant recipients.

Abstract# 496

A New Triage-based Approach to Managing Transplant Referrals

H. L. Walther, *Division of Kidney & Pancreas Transplantation, UCI Health, Orange, CA*

Purpose: To develop and implement a novel triage-based approach to the management of referrals for kidney transplant evaluation

Methods: The transplant nurse coordinator dedicated to referral intake used the triage-based referral management protocol to separate the incoming referrals into three buckets: expedite, routine plus and routine referrals (refer to Figure 1: Triaging patients for scheduling). Expedited referrals were identified as those patients that would be most likely to receive deceased donor organ offers quickly after being added to the waiting list due to extensive time on dialysis and/or those that had an identified living donor. Routine plus and routine referrals were those patients which had less dialysis time accrued or those that just recently started dialysis and had none of the other identified factors to be an expedited candidate. A large bi-monthly pre-transplant education class that could accommodate up to 40 patients as compared to only 6 previously was implemented. All referral patients were eligible to be scheduled and attend education class as soon as possible. Due to limited clinic space availability, at least one appointment slot in each pre-transplant evaluation clinic was reserved for expedited referral patients. If at any time a referral patient's circumstances changed such as an identified living donor candidate coming forward, the patient would be re-triaged to an expedite referral.

Expedite	Routine Plus	Routine
7+ years of dialysis time	4-6 years of dialysis time	<1-3 years of dialysis time
Identified potential living donor	No potential donors	No potential donors
Pre-emptive transplant	Not a pre-emptive transplant	Not a pre-emptive transplant
Untreated Hepatitis C	Does not have untreated Hepatitis C	Does not have untreated Hepatitis C
Simultaneous pancreas/kidney (SPK) transplant candidate	Not an SPK candidate	Not an SPK candidate
"Will likely get an organ offer soon after listing"	**"Fall somewhere in the middle of Routine and Expedite – able to take blood typing into consideration as well, if available"**	**"Will likely be waiting several years on the waitlist after listing"**

Results: Prior to implementation of the new protocol in May 2019, the transplant program had over 350 new patient referrals backlogged along with the regularly incoming referrals. By January 2020, the 350 backlogged referral patients had attended the pre-transplant education class and had either been scheduled for a future appointment, attended their initial evaluation appointment, or had been ruled out by the triage nurse and made not a candidate. Another finding that was not anticipated but welcomed was fewer cancellations and fewer no shows for both the bi-monthly education class and the transplant evaluation appointments. This created further efficiency as scheduled slots for clinic appointments had increased utilization. The nurse coordinator along with administrative and financial coordinators facilitated the transplant program to then begin scheduling all patient's real time as referrals came in.

Conclusions: This triage-based approach to managing transplant referrals ensures that clinical operations for transplant programs are streamlined, the triage nurse and intake team can keep up on processing referrals real-time and ultimately this results in appropriate candidates being added more efficiently to the kidney waiting list.

Abstract# 497

The Effect of Acuity Circles on Deceased Donor Transplant and Offer Rates Across Meld and Exception Statuses

A. Wey[1], S. Noreen[2], S. Gentry[3], N. Salkowski[1], M. Cafarella[2], R. Hirose[4], J. Trotter[5], D. Segev[6], A. Israni[1], J. Snyder[1], B. Kasiske[1], *[1]SRTR, Minneapolis, MN, [2]UNOS, Richmond, VA, [3]USNA, Annapolis, MD, [4]Univ of San Francisco, San Francisco, CA, [5]BSW Health, Dallas, TX, [6]Johns Hopkins, Baltimore, MD*

Purpose: Acuity circles (AC) allocation was implemented on February 4, 2020. AC significantly changed the relative priority of candidates with allocation PELD/MELD scores of 29 to 34. We therefore performed a difference-in-differences analysis for the effect of AC on adjusted deceased donor transplant and offer rates across PELD/MELD categories.

Methods: The before-AC period was February 4, 2019 to February 3, 2020, and the after-AC period was February 4 to March 12, 2020, the day before the national declaration of emergency due to COVID-19. Deceased donor transplant rates used active candidate time on the waiting list during the study period. The deceased donor offer rate was the number of offers in the first 10 spots of match run a candidate received per person-year. Only offers before the final acceptance were included. Transplant and offer rates were adjusted for other candidate characteristics.

Results: Candidates with PELD/MELD 29-32 and PELD/MELD 33-36 had larger differences in transplant rates before and after AC than candidates with PELD/MELD 15-28, while other PELD/MELD categories also had larger but non-significant dif-

ferences compared to candidates with PELD/MELD 15-28 (Figure 1). In contrast, all candidates with PELD/MELD 29 and higher had dramatically larger offers rates before and after AC than candidates with PELD/MELD 15-28 (Figure 2).
Conclusions: Taken together, the implementation of AC increased the relative access to deceased donor transplant for candidates with PELD/MELD of 29-36 without reducing access for candidates with higher allocation priority.

Abstract# 498

27 Months Follow Up of a Cohort in the Transplant Continuum After Using a New Electronic Medical Record Tool to Document Transplant Option Discussions Among Patients with EGFR <20 Ml/min/1.73m2

A. A. Yishak[1], M. S. Bhatnagar[2], A. V. Tomimatsu[3], R. La Londe[4], E. Clark[5], K. B. Rubenstein[6], S. Vupputuri[6], *[1]MAPMG, McLean, VA, [2]Kaiser Permanente |, Oakland, CA, [3]Kaiser Permanente, Oakland, CA, [4]Kaiser Permanente, Oakland,, CA, [5]Kaiser Permanente, Hyattsville, MD, [6]MAPRI, Rockville, MD*

Purpose: The purpose of this study was to assess: 1) the documentation of transplant option discussions; 2) the number of members listed & transplanted preemptively; and 3) transplant opportunity.
Methods: A new tool for documenting Transplant discussion options was implemented in the electronic medical record (EMR) and a cohort from June 13, 2018 was followed over the next 27 months. Our intervention consisted of training providers and case managers how to document transplant option discussions.
Results: A total of 1857 patients with eGFR ≤ 20 mL/min/1.73m2 were identified and of those, 604 (32.5%)) were in transplant continuum (referred, evaluated & waitlisted). Of those in the transplant continuum, 241 members were waitlisted of which 86 (36%) were preemptively listed. Of those 1253 not in the transplant continuum, 1070 did not have documentation of transplant option discussion. See attached cohort diagrams. In 27 months after the EMR tool was implemented, the undocumented transplant discussion improved from 1070 to 1. A total of 642 members were deemed not transplant candidates, of which 400 were above 75 years old & 81 were obese with BMI >40. As of 10/4/20, members in the transplant continuum increased from 604 to 1039, waitlisted from 241 to 447 of which 34.7% are preemptively listed. 151 were transplanted of which 9 were preemptively (out of 56 preemptively listed). Of the 9 preemptive transplants, 3 were from living and 6 were from deceased donor. The number of our waitlisted members per year increased from 70 in 2017 to 90 in 2018 and 120 in 2019. The total number of renal transplants per year increased from 46 in 2017 to 65 in 2018 and 77 in 2019.
Conclusions: We demonstrated a simple, easy EMR tool can help increase documentation of transplant option discussion, waitlisted members and transplant opportunity. This study suggests that patient management for transplant services could be significantly improved and clinical outcomes could potentially be impacted.

Abstract# LB 25

Wave of the Future: Expanding Role and Necessity of the Dedicated Procurement Surgeon

C. Strom, B. Cimsit, H. Nelson, F. Delmonico, *New England Donor Services, Waltham, MA*

Purpose: To evaluate the quantitative and qualitative benefits of a dedicated procurement surgeon (DPS) across the transplant spectrum, including the DPS technical performance value for transplant recipients and the organ procurement organization (OPO). Non-technical benefits of the DPS in optimizing organ utilization include the opportunity to pursue more marginal and kidney-only donors, employment of longer wait times for donation after cardiac death donors, delay of cross clamp during intraoperative liver turn downs, and technical expertise with kidney perfusion pumps.
Methods: We performed a retrospective analysis of technical performance in the recovery of deceased donor abdominal organs within our donor service area (DSA) after the first complete year of an OPO-employed DPS. The DPS performance was compared to surgical recovery data by non DPS surgeons in the same time period, and

also in the two prior years of DSA experience without DPS recovery. Organ damage was classified as tier 1, representing minor technical error, and tier 2, representing surgical damage that rendered organs non-transplantable.

Results: Between January 6, 2020 to January 6, 2021, a total of 946 abdominal organs were procured for transplantation within the DSA. The incidence of DPS surgical damage was 2 of 290 organs (0.69%), and both were tier 1 injuries; there were 0 tier 2 injuries (no organ loss). Incidence of non DPS surgical damage in the same period was 9 of 656 organs (1.4%). Of those 656 organs, there were 6 tier 1 injuries (0.91%) and 3 tier 2 injuries (0.46%) resulting in organ loss. Over the prior two years, 2,145 abdominal organs were procured—all non DPS—with surgical damage noted in 45 organs (2.1%). Tier 1 injuries occurred in 33 of 2,145 organs (1.5%) and tier 2 injuries in 12 of 2,145 organs (0.56%).

Conclusions: The technical expertise of DPS recovery is evident and of significance to the optimization of organ utilization and transplant recipient outcome. Surgical damage of procured organs is not common, but has substantial effects on OPO's, transplant centers, and organ recipients. Maximizing successful organ recovery and utilization is achieved through the creation of the OPO-employed DPS, as we demonstrate substantive differences in technical performance and outcomes of the DPS compared to non DPS surgeons.

DPS and non DPS Procurement and Organ Injury Data			
	2018 and 2019 (all non DPS)	2020 (non DPS)	2020 (DPS)
Abdominal organs procured	2,145	656	290
Organs damaged (% of total)	45 (2.1%)	9 (1.4%)	2 (0.69%)
Tier 1 injuries (% of total)	33 (1.5%)	6 (0.91%)	2 (0.69%)
Tier 2 injuries (% of total)	12 (0.56%)	3 (0.46%)	0

Abstract# LB 26

Peri-operative Liver Transplant Anesthesia Practice Patterns in the United States

C. Crouch[1], A. Hendrickse[1], W. Stoll[2], C. Sullivan[3], M. Kaufman[4], E. Pivalizza[5], D. Damian[6], D. Sellers[7], M. Little[8], S. McCluskey[7], S. Kumar[9], L. De Marchi[10], S. Sridhar[5], T. Sakai[6], *[1]Department of Anesthesiology, University of Colorado, Aurora, CO, [2]Medical University of South Carolina, Charleston, SC, [3]Emory University, Atlanta, GA, [4]Lahey Health, Burlington, MA, [5]University of Texas Health Science Center at Houston, Houston, TX, [6]University of Pittsburgh, Pittsburgh, PA, [7]University of Toronto, Toronto, ON, Canada, [8]University of Texas Health Science Center San Antonio, San Antonio, TX, [9]University of Michigan, Ann Arbor, MI, [10]Georgetown University, Washington DC, DC*

Purpose: Transplant anesthesiology is an evolving subspecialty and has not been the subject of an overall review of practice patterns in the United States since 2013. The Society for the Advancement of Transplant Anesthesia Quality & Standards Committee conducted a survey to evaluate current practice patterns among all transplant programs in the United States.

Methods: A web-based survey was sent to every identified Director of Liver Transplant Anesthesia at each transplant center based on information from the Scientific Registry of Transplant Recipients database. A total of 112 surveys were distributed during a 3-month period ending in January 2021.

Results: Sixty-five responses were collected from both academic and private practice programs. Results showed wide variation in pre-operative evaluation, intraoperative management and postoperative disposition. Interestingly, 41.5% of responding programs report utilize veno-venous bypass; surprisingly, 18.5% of programs do not use any form of intraoperative renal replacement therapy. The use of viscoelastic coagulation testing and transesophageal echocardiography also appears to be expanding amongst transplant anesthesiologists. Pulmonary artery catheters, however, remain common practice in almost half of responding institutions.

Conclusions: Substantial differences exist in liver transplant anesthesiology practice in the United States. Transplant anesthesia is vital for the overall success of multidisciplinary liver transplant programs. This data will prove essential in determining future recommendations as our subspecialty continues to grow.

Basic

Acute Rejection

Abstract# 499

Epigenetic & Functional Changes Associated with Alloreactive Memory CD8 T Cell Subsets in Liver Transplant Patients

H. Abdelsamed[1], S. Liu[1], M. Juya[1], D. Metes[2], F. Lakkis[1], A. Thomson[1], *[1]University of Pittsburgh Medical Center, Pittsburgh, PA, [2]UPMC, Pittsburgh, PA*

Purpose: Donor-specific allo-reactive memory CD8 T cells play a pivotal role in allo-immunity and represent a major hurdle against tolerance induction in solid organ transplantation. Hence, there is a critical need to understand the mechanisms regulating their development, function and maintenance.

Methods: Since epigenetic modifications play a major role in a wide range of biological processes and diseases, we sought to understand these mechanisms through the lens of epigenetics.

Results: Here, we report epigenetic and functional changes in alloreactive memory CD8 cells isolated from stable vs acutely-rejecting liver transplant patients each receiving standard of care immunosuppressive therapy. We observed low frequencies

of dividing naïve and memory CD8 T cell subsets in stable liver transplant patients compared to rejecting counterparts in mixed leukocyte reactions (CTV-MLRs). Surprisingly, the majority of the allo-reactive memory CD8 T cells were found in the central memory subset (TCM) sorted from rejecting patients. Using gold-standard methods for DNA methylation analysis, we observed hyper-methylation of effector-associated (IFNγ and CD69), costimulatory molecules (CD28 and CD70), and coinhibitory molecule CTLA-4 in TCM alloreactive CD8 T cells sorted from stable liver transplant patients compared to the rejecting group.

Conclusions: These novel data demonstrate that effector-associated epigenetic programs are acquired during allo-antigen-induced proliferation of memory CD8 T cells in stable liver transplant patients, which could be targeted for potential epigenetic-based therapies in solid organ transplantation.

Abstract# 500

Association Between Donor-Recipient Genetic Matching and Acute Rejection in Kidney Transplantation

R. Cao[1], V. Arthur[2], J. Chen[2], B. Keating[2], C. Dorr[3], D. Schladt[3], G. Onyeaghala[3], R. Mannon[4], A. Matas[1], R. Remmel[1], N. Pankratz[1], B. Wu[1], W. Oetting[1], P. Jacobson[1], A. Israni[3], W. Guan[1], *[1]University of Minnesota, Minneapolis, MN, [2]University of Pennsylvania, Philadelphia, PA, [3]Hennepin Healthcare Research Institute, Minneapolis, MN, [4]University of Nebraska, Omaha, NE*

Purpose: In this study we carried out a genome-wide association study (GWAS) between donor-recipient matching scores at individual SNP level and Acute rejection (AR) in kidney allograft recipients, aiming at finding potential genetic regions which are associated with AR posttransplant.

Methods: Recipients with European ancestry from the Deterioration of Kidney Allograft Function (DeKAF) Genomics were analyzed with their matched living donors (n = 784 pairs). All donors except one were with European ancestry. The study evaluated AR events (n=161) post-kidney transplantation. Donor-recipient matching score was defined by the identify-by-state (IBS) between donor and recipient genotypes. Association between matching scores and AR was tested using Cox regression, adjusting for recipient age at transplantation, gender, prior non-kidney transplantation, and PRA (positive or negative). Bonferroni correction was applied to control for multiple testing.

Results: There were 13 single-nucleotide polymorphisms (SNPs) at which donor-recipient matching scores were significantly associated with AR ($p<5E-08$). The strongest association was observed for an intronic variant rs6749137 ($p=1.78E-09$), which is located in the *CPS1* gene region. The *CPS1* gene codes a mitochondrial enzyme which catalyzes synthesis of carbamoyl phosphate from ammonia and bicarbonate, important in the removal of excess urea from cells. Other associated gene regions include *SOX6* and *CNOT6* (Table 1).

Conclusions: We identified novel variants beyond human leukocyte antigen (HLA) region where the matching between donor and recipient was associated with AR. The results need to be further validated in external cohorts. Functional analysis of these SNPs will be required. Identification of genetic regions besides the HLA region will improve matching between kidney transplant recipients and their donors, and achieve beneficial outcome post-transplant.

Abstract# 501

Murine Cytomegalovirus Induces Kidney Allograft Injury via Th17 Cells Recruited by Both Viral Antigen-Specific and Cytokine/chemokine Mediated Pathways

R. Dhital[1], V. Velazquez[1], Q. Zeng[2], B. Graber[1], K. Flint[1], M. Shimamura[1], *[1]Vaccines and Immunity, Nationwide Children's Hospital, Columbus, OH, [2]Center for Cardiovascular Research, Nationwide Children's Hospital, Columbus, OH*

Purpose: Cytomegalovirus infection in transplant recipients has been associated with renal allograft rejection and graft failure. We have previously shown that murine CMV (MCMV) infected allografts have greater infiltration of T helper 17(Th17) cells compared to uninfected transplants and are associated with more severe allograft injury. We hypothesized that only a fraction of these Th17 cells are CMV specific and are phenotypically different than the rest of the Th17 cells that infiltrate the allograft via alternate antigen independent mechanism.

Methods: Murine renal transplantation was performed between Donor BALB/cJ and recipient C57BL/6J/ OT-II/ IL-17A-GFP reporter mice (N=3-5 mice/group). The mice were infected with MCMVΔ157 at 10^6 pfu intraperitoneally for D+R+ transplants. At post-transplant day 7, leucocytes from allografts were stimulated with PMA-Ionomycin or MCMV peptide pool and were analyzed for polyfunctionality for CD4+ cells expressing cytokines (TNFα, IFNγ and IL17A) and chemokine receptors (CCR6, CCR4 and CXCR3). Intragraft level of Th cell associated cytokines were quantified using cytokine bead array.

Results: Compared to D-R-, allografts from D+R+ transplants had 1.75-fold higher frequency of $CD4^+IL17A^+$Th17 cells that co-expressed higher frequencies of $IL17A^+IFN\gamma^+$($p=0.0166$) and $IL17A^+TNF\alpha^+IFN\gamma^+$($p=0.0075$). CMV specific Th17 cells in the D+R+ allografts constituted an average of 5.47±0.96% of the total Th17 cells and predominantly expressed $IL17A^+IFN\gamma^+$. The CMV infected allografts also had 18.9-fold higher infiltration of antigen non-specific (OVA tetramer+) CD4+cells and Th17 cells ($p=0.0009$) that more often co-expressed IL17A and TNFα. The intragraft level of Th17 differentiating cytokines, IL6, IL1β and IL23 showed a higher trend in D+R+ group, compared to D-R- group. D+R+ allografts had greater proportion of Th17 cells expressing CCR6 ($p=0.0235$) or CXCR3 ($p= 0.0235$) alone or in combination ($p= 0.0235$), compared with D-R- allografts.

Conclusions: Cytomegalovirus infection induces the infiltration of CMV specific $IL17\text{-}A^+IFN\text{-}\gamma^+$ as well as antigen non-specific $IL17\text{-}A^+TNF\text{-}\alpha^+$ polyfunctional Th17 cells into the allografts. The allograft microenvironment favors the cytokine mediated differentiation of naïve T cells to polyfunctional Th17 cells. Additionally, recruitment of Th17 cells in CMV infected allografts are mediated by CCR6 and CXCR3 during allograft rejection. These data suggest that multifunctional inflammatory cytokine expressing Th17 cells infiltrate MCMV infected allografts by both antigen- dependent and -independent mechanisms in CMV infected allografts. Therefore, blockage of Th17 recruitment into the allograft can be good target to prevent Th17 mediated allograft injury in clinical solid organ transplantation.

Abstract# 502

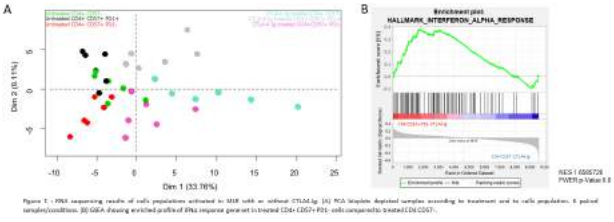
Belatacept-Resistant T Cells are Activated by IFNα-IRF7 Pathway

F. Herr, K. Bargiel, A. Vernochet, A. Durrbach, *UMR1186, Villejuif, France*

Purpose: Second signal of activation play an important role in activation of T lymphocytes. Their control by checkpoint inhibitor is efficient in auto-immune disease and allogenic transplantation. Belatacept, a CTLA4-Ig, has been developed to control activated T cells in renal transplantation as a maintenance therapy (Larsen et al. 2006). Belatacept has been demonstrated to improve the renal function, to increase graft and patient survival as compared to Calcineurin Inhibitor (CNI) (Vincenti et al. 2010). Belatacept is associated with reduced cardiovascular risk and occurrence of anti-donor antibodies, but also with a higher risk of acute cellular rejection (ACR) than observed with CNI (Rostaing et al. 2013). A previous study linked Acute Cellular Rejection (ACR) of belatacept-treated patients with the rate of CD4 CD57+PD1- T cells before transplantation. *In vitro* we showed that expansion of these cells is belatacept-resistant (Espinosa et al. 2016).

Methods: In this study we assessed activation mechanism of CD4 CD57+PD1- T cells in order to control their proliferation. We performed a transcriptomic analysis of CD4 CD57+PD1- cells from 6 donors after Mixed Leucocyte Reaction (MLR) with +/- belatacept. Then we assessed in MLR the activation pathway found by a computational method of analysis.

Results: A Principal Component Analysis demonstrated different transcriptional profiles between cells of interest and control populations (Fig1A). Belatacept have a weaker effect on pro-proliferative pathways of CD4 CD57+PD1- cells than on CD4 CD57-. A Gene Set Enrichment Analysis shows that Interferon (IFN) α response gene set is positively regulated in treated CD4CD57+PD1- cells (Fig1B).



This pathway is associated with an increase of IFN Regulatory Factor (IRF) 7 transcripts which control the pro-inflammatory cytokine IL6. *In vitro* we confirmed IRF7 over-expression in CD4 CD57+PD1- cells. Then we showed inhibition of CD4 CD57+PD1- cells proliferation by blocking type I IFN or IL-6 receptors with belatacept (Fig2).

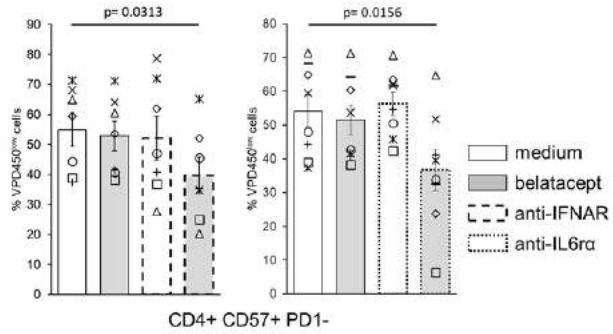


Figure 2: Inhibition of CD4 CD57+ PD1- cells proliferation. Proliferation of cells have been assessed by VPD450 dilution after 5 days of MLR with anti-IFNAR1/2, anti-IL6R and CTLA4-Ig. 8 independent experiments, Wilcoxon test analysis.

Conclusions: We demonstrated that activation of CD4 CD57+PD1- belatacept-resistant T cells is dependent of the IFNα-IRF7 pathway. *In vitro* inhibition of these cells by antiIFNAR or antiIL6rα blocking antibodies highlight new therapeutic options to prevent belatacept associated ACR.

Abstract# 503

Successful Prophylaxis of Antibody-Mediated Rejection by Downregulation of C5 Expression via RNA Interference in a Rat Kidney Transplant Model

H. Ishigooka[1], S. Motoi[2], T. Yamakawa[1], C. Matsui[2], Y. Suzuki[3], R. Ishii[1], K. Saiga[1], D. Tokita[1], T. Imai[2], K. Tanabe[1], *[1]Urology, Tokyo Women's Medical University, Tokyo, Japan, [2]KAN Research Institute, Inc., Kobe, Japan, [3]Tsukuba Research Laboratories, Eisai, Co., Ltd., Ibaraki, Japan*

Purpose: Antibody-mediated rejection (AMR) is a major contributor towards poor prognosis in kidney transplantation. Circulating donor-specific antibodies (DSAs) cause AMR with complement activation. This study was conducted to evaluate the efficacy of a lipid nanoparticle formulation of small interfering RNA against complement C5 (C5 siRNA-LNP) for AMR in a rat kidney transplantation model.

Methods: Seven- to nine-week-old Lewis recipient rats were sensitized by skin grafting from Brown Norway donor rats, and kidney transplantation was performed at four weeks post-sensitization. Graft survival was followed up for 100 days post-transplantation. The grafts were histopathologically assessed using periodic acid-Schiff-stained images taken seven days after the transplantation. The serum levels of DSA-IgG were measured by flow cytometric crossmatch using molecules of equivalent soluble fluorochromosome. Suppression of C5 expression and complement activity was confirmed via Western blotting and hemolysis assays, respectively.

Results: C5 siRNA-LNP completely suppressed C5 expression and complement activity (hemolysis ≦ 20%) one week after its administration, and the suppressive effect was maintained up to 2 weeks later. Its weekly administration continued to suppress complement activity. C5 siRNA-LNP monotherapy (median survival time, MST: 8 days), combined therapy with C5 siRNA-LNP and cyclosporine (C5 siRNA+CsA, MST: 14 days), and treatment with CsA and deoxyspergualin (CsA+DSG, MST: 17 days) failed to prolong graft survival, whereas combination treatment with the three compounds (C5 siRNA+CsA+DSG, MST: 55.5 days) significantly prolonged graft survival (*P*=0.179, vs. CsA+DSG, log-rank test) (Figure). DSA-IgG was persistently present in peripheral blood in the triple-drug combination group. Severe mononuclear cell interstitial inflammation and moderate to severe peritubular capillaritis were observed in the CsA+DSG group but not in the triple-drug combination group.

Conclusions: AMR can be controlled by downregulating C5 expression along with the suppression of immune cell functions, such as T and B cells, even in the presence of DSAs without desensitization therapy.

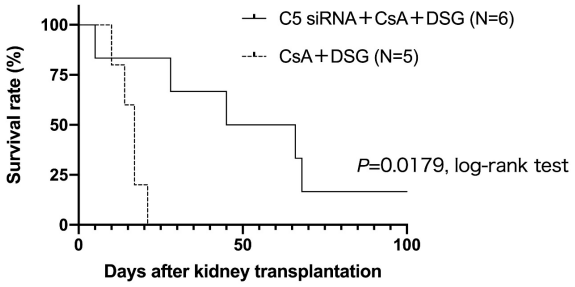

Figure: Prophylactic effect of C5 siRNA-LNP treatment on graft survival in a rat AMR model

Abstract# 504

The Microenvironment of Belatacept-Resistant Rejection

A. Johnson, J. Zhang, C. Larsen, *Surgery, Emory University, Atlanta, GA*

Purpose: Belatacept is a co-stimulation blockade immunosuppressant, that despite demonstrating improved long-term outcomes, has not been widely adopted, in part, due to concern over early episodes of acute rejection. A method of co-immunosuppression with transient calcineurin inhibitor (CNI) therapy has improved rejection

rates, but importantly, has also clearly defined a population of patients well controlled on CNIs but who develop rejection when that therapy is withdrawn. We aim to characterize the microenvironment of that rejection.

Methods: We selected formalin fixed paraffin embedded biopsies from 5 historical patients with Banff 2B acute rejection in the setting of CNI weaning. From these biopsies, we sequenced the β chain of T cell receptors (TCR) to analyze clonality of the T cells infiltrating biopsies. TCR sequences were analyzed with the R biostatistical package immunarch as well as Adaptive Biotechnologies ImmunoSeq Analyzer tool. In addition, we performed multiplex immunofluorescence to characterize the immune cells infiltrating these biopsies. Primary antibodies against CD4, CD8 and MHCII were used along with a DAPI stain to allow cell identification. Slides were imaged with a Nikon Leica Spinning Disk microscope, and image processing performed using Fiji software.

Results: There was an average of 3078 total and 2542 productive templates per sample, with 82% of templates productive. Productive Simpson clonality ranged from 0.02 to 0.057. The maximum productive frequency in sample s16_1 was 4.5%. The remaining samples had maximum productive frequencies between 0.4 and 1.1%. There was minimal repertoire overlap between samples. Analysis of V and J gene usage revealed a high frequency of BJ02-07 usage in all samples. Immunofluorescence imaging revealed a high density of both CD4 and CD8 cells, with a paucity of MHCII expressing cells.

Conclusions: Though individual clones do not predominate in these biopsies, V/J gene usage suggests high levels of similarity among clones. We plan to quantify this with CDRdist scoring, a method based on Smith-Waterman alignment calculation. Qualitative immunofluorescence data will be processed with CellProfiler software to analyze spatial relationships between cell types.

Abstract# 505

The Efficacy of Delayed Fc-nonbinding Anti-CD3 Antibody Treatment in Sensitized Allogeneic Mouse Heart Transplantation

T. Ota[1], R. Goto[1], R. Kanazawa[1], K. Shibuya[1], Y. Ganchiku[1], N. Kawamura[2], M. Watanabe[2], M. Fukai[1], T. Shimamura[3], A. Taketomi[1], *[1]Dept. of Gastroenterological Surgery I, Hokkaido University, Sapporo, Japan, [2]Dept. of Transplant Surgery, Hokkaido University, Sapporo, Japan, [3]Division of Organ Transplantation, Hokkaido University Hospital, Sapporo, Japan*

Purpose: *Delayed* treatment with Fc-nonbinding anti-CD3 antibody (ab) permits early graft infiltrating cells to promotes a transplant tolerance. However, graft infiltrating cells immediate after transplantation includes alloreactive memory T cells in sensitized situation, which may abrogate a tolerogeneic effect in *delayed* treatment protocol.

Methods: Sensitized splenocytes were obtained from recipient C57BL/6 (B6, $H2^b$) mice grafting cardiac allograft from BALB/c ($H2^d$) in 7 to 11 weeks post-transplantation. Naïve B6 mice were adoptively transferred with $15x10^6$ sensitized splenocytes at 2 or 3 days before grafting $H2^d$ heart and then treated with delayed anti-CD3F(ab')$_2$ treatment (anti-CD3F(ab')^2 for 5 days starting from 3 days post-transplantation).

Results: *Early* anti-CD3F(ab')$_2$ treatments for 5 days (day -1 to 3) significantly prolonged graft survival in BALC/c-to-B6 heart transplant model (n=5, median survival time [MST] 38 days , p=0.001 , vs. untreated control). Further, *delayed* anti-CD3F(ab')$_2$ treatments for 5 days (day 3 to 7) promoted indefinite graft survival (MST >100 days) which data is consistent with previous reports (Goto R et al., AJT 2012). Then we applied this *delayed* anti-CD3F(ab')$_2$ treatment to sensitized mice. Sensitized B6 mice promptly rejected $H2^d$ cardiac allografts within 7 days as shown in Figure 1A (n=5, black circles, p=0.003 , vs. B6 mice transferred naïve splenocytes, n=5, MST 8 days, dotted line). We also observed significant increased numbers of sensitized splenocytes were infiltrated within an allograft by CTV staining technique (n=5, $p<0.05$ vs. naïve cells transferred model). Interestingly, *delayed* anti-CD3F(ab')$_2$ treatments efficiently reduced the number of sensitized graft infiltrating cells (Fig.1B) and promoted long-term graft acceptance (n=5, MST>80 days, empty circles in Fig.1A).

Conclusions: *Delayed* anti-CD3F(ab')$_2$ treatment strategy allows long-term graft acceptance despite sensitized situation. In the development of Fc-nonbinding humanized anti-CD3 antibody, our findings would be useful in clinical organ transplantation.

Abstract# 506

Pharmacokinetic and Toxicity Studies of an Anti CD40L Antibody, At-1501 in Rhesus Macaques

S. Perrin[1], A. Gill[2], C. Gill[2], F. Vieira[2], K. Thompson[2], *[1]Novus Therapeutics, Irvine, CA, [2]ALS Therapy Development Institute, Cambridge, MA*

Purpose: CD40L is a costimulatory receptor for CD40 found on T helper cells. Binding of CD40L on T cells to CD40 on antigen presenting cells induces downstream immune and inflammatory responses. Inhibition of CD40L signaling can abolish inflammation, induce T cell anergy, prevent the progression of autoimmunity, and instill transplant tolerance. AT-1501 is a humanized anti-CD40L antibody lacking Fc effector function with high affinity binding to CD40.

Methods: A pharmacokinetic study of AT-1501 at 1, 10 and 50 mg/kg was undertaken in rhesus macaques. In addition, we conducted 12 (3, 10, 30, 50 mg/kg) and 26 week (100, 200 mg/kg) toxicology studies with weekly dosing of AT-1501.

Results: The pharmacokinetic study demonstrated a half-life of 7-9 days at 50 mg/kg. Variability was apparent at lower doses, which was attributed to immunogenicity of AT-1501 in rhesus macaques responding to a human antibody. Plasma concentrations contributing to AUC were affected by the induction of anti-drug antibodies (ADA) and occurred markedly at 1 mg/kg, to an intermediate extent at 10 mg/kg, and was absent at 50 mg/kg. At 10 mg/kg, half of the animals elicited ADA responses, which were non-neutralizing and did not impact AT-1501 binding to CD40L at either 3 or 10 mg/kg. ADA responses were not observed above 10 mg/kg. All animals in the 100 mg/kg dose group completed the study, remained healthy and AT-1501 concentrations in plasma were as predicted. Animals in the 200 mg/kg group survived through 16 weeks without evidence of gross pathology. Four 200 mg/kg animals showed signs of toxicity and were euthanized at 17, 18, 25 and 26 weeks. Data were suggestive of a Type III hypersensitivity infusion reaction (IR) resulting in immune-complex (IC) formation, impacting multiple organs but primarily resulting in kidney pathology and dysfunction. Clinical chemistry and histopathology confirmed extravascular localization of AT-1501, NHP IgG1, IgM, Albumin, and C3. ICs were comprised of IgM, demonstrating that AT-1501 blocked IgM to IgG class switching.

Conclusions: These data demonstrate functional activity of AT-1501 in vivo. Thus, weekly doses of AT-1501 at 10 mg/kg or higher are considered therapeutic dosing, leading to levels that inhibit antigen presentation and pro-inflammatory lymphocyte signaling. The results for the 200 mg/kg group support a conclusion that the toxicity was due to the high concentration of circulating AT-1501, leading to IC formation and not due to the mechanism of action of the drug.

Abstract# 507

Belatacept and Rapamycin Maintenance Immunosuppression in a Sensitized Nonhuman Primate Kidney Allotransplantation Model

R. Schmitz[1], Z. W. Fitch[1], M. Manook[1], J. Yoon[1], A. B. Farris[2], J. Kwun[1], S. J. Knechtle[1], *[1]Department of Surgery, Duke University Medical Center, Durham, NC, [2]Department of Pathology and Laboratory Medicine, Emory University School of Medicine, Atlanta, GA*

Purpose: Desensitization with costimulation blockade and proteasome inhibition prior to kidney transplantation prevents early antibody-mediated rejection (AMR) and prolongs graft survival in highly sensitized nonhuman primates (NHP). However, recipients develop late AMR accompanied by elevation of Tfh and plasma cells. Therefore, we hypothesized that belatacept as a maintenance immunosuppression would control the post-transplant humoral immune response in conjunction with rapamycin.

Methods: Nine (9) rhesus macaques were sensitized to maximally MHC mismatched donors by two sequential skin transplants. Primates were desensitized with belatacept and carfilzomib. Following desensitization, primates received kidney allografts from their skin donors. Five primates received induction therapy with rhesus specific anti-thymocyte globulin (rhATG) and four primates received induction therapy with anti-CD4 and anti-CD8 monoclonal antibodies. Maintenance immunosuppression of all primates consisted of belatacept, rapamycin and prednisone.

Results: All primates tolerated the treatment well. In the rhATG group (n=5), we observed 3 cases of early graft rejection without DSA elevation, while we had no rejection 3 months post-transplant in the anti-CD4/8 group (p=0.08; **Figure 1A**). As expected, more significant depletion of CD8+ T cells was induced with the monoclonal antibodies compared to rhATG (**Figure 1B**). While preventing early graft rejection, the use of anti-CD4 and anti-CD8 mAbs increased the frequency of CMV reactivation requiring treatment (**Figure 1C**). Interestingly, all six animals that survived long-term showed no AMR under belatacept and rapamycin maintenance immunosuppression. We were furthermore able to wean immunosuppression to belatacept monotherapy in one primate and wean all immunosuppression in a second primate without observing graft dysfunction for at least 3 months.

Conclusions: Maintenance immunosuppression with belatacept and rapamycin prevents post-transplant AMR and allows for weaning of immunosuppression in highly sensitized nonhuman primate kidney transplant recipients. Induction therapy with anti-CD4 and anti-CD8 monoclonal antibodies prevents early ACR, which was observed with rhATG.

Abstract# 508

Inhibition of Fatty Acid Beta-Oxidation Prolongs Heart Allograft Survival

B. W. Wong, Y. Zhu, H. Dun, L. Ye, *Surgery, Washington University School of Medicine, Saint Louis, MO*

Purpose: To test the therapeutic efficacy of pharmacological inhibition of fatty acid beta-oxidation (FAO) on acute heart allograft survival.

Methods: We used a heterotopic *Balb/c* donor heart to *C57Bl/6* recipient mouse transplant model and tested the therapeutic efficacy of pharmacological inhibition of the rate-limiting FAO enzyme, carnitine palmitoyltransferase 1 (Cpt1), using the drug etomoxir. We assessed heart allograft survival by direct palpation of the transplanted heart, and assessed rejection by histology and immune cell infiltration. We further assessed immune cell composition in the transplanted heart, native heart, spleen and draining mediastinal lymph node by flow cytometry. Further, we assessed T cell activation by ELISPOT assay on splenocytes from heart transplants treated with vehicle or etomoxir using *Balb/c*-derived activated antigen-presenting cells (APCs). Finally, we utilized adoptive transfer of CD45.1$^+$ monocytes and in vitro monocyte differentiation assays to assess the effects of FAO inhibition *in vivo* and *in vitro*.

Results: Pharmacological inhibition of FAO significantly improved heart allograft survival, while reducing T cell infiltration and activation, and reducing the numbers of dendritic cells and macrophages within transplanted hearts in recipients treated with etomoxir, compared with those treated with vehicle controls. Splenocytes from heart transplanted recipients treated with etomoxir were less reactive to a general stimulus (concanavalin A) or allo-specific stimulus (activated *Balb/c* APCs). Adoptive transfer of CD45.1$^+$ monocytes revealed reduced monocyte-to-macrophage and monocyte-to-DC differentiation *in vivo*, and *in vitro* monocyte differentiation assays confirmed this observation.

Conclusions: Pharmacological inhibition of FAO is a promising therapeutic target that prolongs heart allograft survival, in part, through modulating monocyte differentiation, resulting in reduced T cell activation.

Abstract# 509

Re-Transplantation of Mouse Kidney Grafts to Study Local Immune Responses

D. Zhao, M. Oberbarnscheidt, F. Lakkis, K. Khodor, *Starzl Transplantation Institution, Pittsburgh, PA*

Purpose: Mouse kidney transplantation has been widely used to study the immune response to allogeneic grafts. This response includes a circulating systemic compartment and a resident non circulating one. A distinction between these compartments remains an important caveat to the interpretation of the resident or local immune response's importance and function. This study aimed at developing a mouse kidney allograft re-transplantation model as a tool to investigate the local immunity in the grafts.

Methods: In primary kidney transplantation, the donor aorta (AO) was anastomosed to the recipient AO using "interrupted 6-stitch end-to-side" method. The donor renal vein was anastomosed to the recipient inferior vena cava (IVC) using end-to-side continuous suturing method. The donor ureter was implanted into the recipient bladder and secured to the posterior wall of the recipient bladder. In the re-transplantation,

the graft renal artery with a segment of the primary donor mouse's AO and a segment of the primary recipient mouse's AO was end-to-side anastomosed to the secondary recipient mouse's AO. The graft renal vein with a segment of the primary recipient's IVC was end-to-side anastomosed to the IVC of the secondary recipient mouse. A total of 3-4 well-proportioned stitches are applied to fix the ureter graft onto the posterior wall of the secondary recipient mouse's bladder.

Results: In syngeneic re-transplantation, the graft tissue architectures were normal and well maintained comparable with the primarily transplanted syngeneic graft. In allogenic re-transplantation, we firstly confirmed resident memory T cells formed and functioned in the kidney allografts by using this model. Our detailed, stepwise protocol can be stably replicated for both the primary and secondary, donor and recipient operations. The techniques in this protocol can be efficiently completed by an individual proficient in mouse kidney transplantation surgical procedures.

Conclusions: We successfully developed a mouse kidney re-transplantation model, which had not been previously described and can be harnessed in studying local immunity in the grafts.

Abstract# 510

Invariant Nkt Cells Promote Expansion of Novel Cxcr3$^+$Ccr4$^+$Cd8$^+$ T Cells in the Liver Following Allogeneic Hepatocyte Transplant

J. Zimmerer[1], B. Ringwald[2], S. Chaudhari[1], J. Han[1], C. M. Peterson[1], R. T. Warren[1], M. Hart[1], M. Abdel-Rasoul[3], G. Bumgardner[1], *[1]OSU, Columbus, OH, [2]Medical Student Research Program, OSU, Columbus, OH, [3]Center for Biostatistics, OSU, Columbus, OH*

Purpose: Hepatocyte transplantation represents a treatment for metabolic diseases and a bridge therapy to whole organ transplant but is limited in part by cell immunogenicity. Our prior work identified the critical role of both CD4-dependent and CD4-independent CD8$^+$ T cells in mediating hepatocyte rejection. We evaluated the influence of invariant natural killer T (iNKT) cells, known to be uniquely abundant in the liver, upon CD8-mediated immune responses in the presence and absence of CD4$^+$ T cells.

Methods: C57BL/6 (wild-type; WT), iNKT deficient Jα18 KO, and RAG1 KO mice (all H-2^b) were transplanted with FVB/N (H-2^q) hepatocytes. Cohorts of each strain were depleted of CD4$^+$ T cells. Some, cohorts of Jα18 KO mice received iNKT cell adoptive transfer. Recipients were evaluated for CD8-mediated *in vivo* and *in vitro* cytotoxicity, CD8$^+$ T cell phenotype, and allograft rejection.

Results: By comparing CD4-sufficient WT recipients to CD4-sufficient, iNKT cell-deficient Jα18 KO recipients, the presence of iNKT cells significantly enhanced CD8-mediated *in vivo* allocytotoxicity (WT= 83.8 ± 3.3%, n=15 vs. Jα18 KO 23.4 ± 3.1%, n=15, p<0.0001) but did not affect allograft median survival time (WT= 10 days, n=15 vs. Jα18 KO= 14 days, n=10; p>0.05). However, in the absence of CD4$^+$ T cells, iNKT cells were critically important for CD8-mediated *in vivo* allocytotoxicity (WT= 31.1 ± 3.1%, n=14 vs. Jα18 KO= 1.9 ± 0.7%, n=16, p<0.0001) and allograft median survival time (WT= 14 days, n=12 vs. Jα18 KO= 56 days, n=7, p<0.0001). Adoptive transfer of iNKTs restored cytotoxicity to WT levels (not shown). iNKT cells significantly enhance the quantity of a novel CD8$^+$ T cell subset (alloprimed CD44$^+$IFN-γ$^+$CXCR3$^+$CCR4$^+$CD8$^+$ T cells) in the liver (2-fold) of both CD4-sufficient and CD4-deficient recipients posttransplant (p<0.035 for all comparisons). When compared to alloprimed CD8$^+$ T cells that lack CCR4 expression (CXCR3$^+$CCR4$^-$CD8$^+$ T cells), CXCR3$^+$CCR4$^+$CD8$^+$ T cells express higher amounts of IFN-γ (32.0 ± 3.2%, n=9 vs. 9.1± 1.2%, n=9; p<0.0001) and TNF-α (37.0 ± 3.0%, n=9 vs. 6.6 ± 1.3%, n=9; p<0.0001). In addition, CXCR3$^+$CCR4$^+$CD8$^+$ T cells are more potent than CXCR3$^+$CCR4$^-$CD8$^+$ T cells since the transfer of small quantities (250 x 10^3 cells) induced significantly greater *in vivo* cytotoxicity (13.3 ± 1.1%; n=7, vs. 5.4 ± 0.6%; n=9; p<0.0001) and rapid hepatocyte rejection following adoptive transfer into RAG1 KO recipients with stable hepatocellular allografts (MST= day 5, n=4 vs. day 21, n=3; p=0.02).

Conclusions: iNKT cells enhance the expansion of highly cytotoxic alloprimed CXCR3$^+$CCR4$^+$CD8$^+$ T cells that mediate rapid rejection of allogeneic hepatocytes transplanted to the host liver.

Environmental Factors That Shape T-cell Alloimmunity: Role of the Microbiome

K. Janek[1], J. H. Fechner[1], R. A. Daley[1], K. Krautkamer[1], F. Rey[2], J. D. Mezrich[1], *[1]Surgery, University of Wisconsin School of Medicine & Public Health, Madison, WI, [2]Bacteriology, University of Wisconsin, Madison, WI*

Purpose: Unlike other types of immunity, T-cell alloimmune responses to mismatched MHC proteins do not need priming by a previous exposure. While genetic differences between a recipient and donor are central to the strength of the alloreactive T cell, environmental factors can play a role. We hypothesize that the gut microbiome (MB) has a significant role in establishing an alloimmune response.

Methods: Using an internal renal transplant (RTx) registry of patients between ages 18-70 with no prior other organ tx, and no active infections, 58 patients at various points in their clinical course (on the waiting list, recent RTx, remote tx) were enrolled in our IRB-approved study. Stool samples from 36 of these patients, plus 5 enrolled healthy controls, were cryopreserved and bacterial composition was identified by 16s rRNA sequencing and analyzed for differences in operational taxonomic units. Germ-free mice (GF; 4 - 5 weeks old; C57BL/6 (B6) background) were conventionalized with fecal tx from individual Rtx patients. After 8 weeks, mice were euthanized and spleen was harvested for intracellular cytokine staining/ flow cytometric analysis and mixed lymphocyte reactions (MLR) against irradiated B6, Balb/c or C3H stimulator cells. Culture supernatants were collected on day 5 and analyzed for interferon gamma (IFNγ) by ELISA.

Results: Analysis of the bacterial composition of the feces revealed that >75% of the MB from RTx patients were substantially different than those of healthy controls. Eight weeks after colonization of GF, flow cytometric analysis revealed minimal differences between colonized GF and controls with respect to CD4 T cells. There were striking differences in CD8 T cells, in particular, the fraction of CD8 T cells that produce IFNγ. Mice colonized with fecal material from 2 RTx patients with type-2 diabetes had a significantly higher % of IFNγ-expressing CD8 T cells compared to control B6 mice or the mice colonized with fecal material from 2 other RTx patients. MLRs were generated using spleens from 3 sets of GF mice (n = 4 - 5 per set) conventionalized with fecal material from 1 of 3 RTx patients plus B6 controls (n=6). As shown below, GF mice colonized with Pt440 material had significantly higher IFNγ production than Pt 535 or B6 controls against Balb/c. In contrast, Pt132-colonized GF had a higher response to C3H compared to both Pt440 and Pt535 as well as the B6 control.

Conclusions: The data supports the hypothesis that recipient MB has the potential to alter the peripheral alloreactive T cell response.

Abstract# 512

The Development and Characterization of AT1501, an Anti CD40L Antibody Lacking Fc Effector Function

S. Perrin[1], A. Gill[2], C. Gill[2], F. Vieira[2], K. Thompson[2], J. Lincecum[2], B. Jiang[2], *[1]Novus Therapeutics, Irvine, CA, [2]ALS Therapy Development Institute, Cambridge, MA*

Purpose: CD40L is a costimulatory type II membrane receptor for CD40. The binding of CD40L on T helper cells to CD40 on antigen presenting cells induces multiple downstream immune and inflammatory responses, including B and T cell clonal expansion, antibody production and the production of pro-inflammatory cytokines and chemokines. Hu5c8 is an IgG1 antibody with high affinity binding to CD40L

and was a promising candidate for organ transplant and autoimmune disease, but unpredicted on-target toxicity due to Fc effector and platelet activation, resulted in thromboembolic events in humans. AT-1501 contains point substitutions in the Fc region of the antibody, wherein three cysteine residues are substituted with serine and one proline residue is substituted with serine. We analyzed the binding affinity of AT-1501 and verified both functional activity and lack of binding to FCγRs or C1q.
Methods: Functional blocking of CD40L signaling was demonstrated by utilizing a HEK293 cell line expressing CD40 on the cell surface and by inhibition of downstream NFKB signaling in a cell lysate assay. PAC-1 is a protein expressed on the surface of activated platelets and was analyzed verify lack of platelet activation. We used CD40L specific antibodies to block function.
Results: AT-1501 and 5c8 have similar binding affinity to CD40L with an EC50 of 100 ng/mL. Unlike 5c8, the amino acid modifications in AT-1501 ablate Fc-effector function with no detectable binding to FCγRs or C1q. Pre-incubation of CD40L with AT-1501 blocked the binding to CD40 on the cell surface and inhibited NFκβ signaling. In our antibody competition studies incubation with AT-1501 demonstrated inhibition of AF488-5c8-(F(Ab')2 binding to CD40L expressing HEK293 cells equivalent to the reference 5C8 antibody. Similarly, AT-1501 inhibited the binding of AF488-5c8-F(Ab')2 to activated human peripheral blood lymphocyte cells. Positive control 5c8:sCD40L immune complexes (ICs) caused platelet activation leading to surface PAC-1 expression. Critically, PAC1 staining was undetectable in untreated platelets or platelets exposed to AT-1501:sCD40L ICs demonstrating the improved safety profile of AT-150
Conclusions: Our results support further clinical development of AT-1501 for transplantation and autoimmune indications.

Abstract# 513

DAP12 Promotes Liver DC Tolerogenicity by Negative Regulation of the CGAS-STING-IFN I Pathway

Y. Zheng[1], J. Long[2], N. Ryosuke[1], L. Peng[3], F. Peng[3], A. Thomson[1], *[1]Thomas E. Starzl Transplantation Institute, University of Pittsburgh, Pittsburgh, PA, [2]Department of Cardiology, The Second Xiangya Hospital of Central South University, Changsha, China, [3]Department of Kidney Transplantation, The Second Xiangya Hospital of Central South University, Changsha, China*
Purpose: Constitutive expression of comparatively high levels of DNAX-activating protein of 12KDa (DAP12) by liver myeloid dendritic cells (mDCs) has been implicated in their immune regulatory function. DAP12 knockout (KO) liver mDCs exhibit augmented migratory responses to secondary lymphoid tissue and enhanced ability to elicit alloreactive T cell responses in mice that may contribute to failure of DAP12 KO livers to induce spontaneous transplant tolerance. However, underlying mechanisms are unclear. There is recent evidence that in human and mouse DCs, DAP12 negatively regulates type I interferon (IFN-I) production, that is a high-risk factor for graft loss. IFN-I production can be initiated by retinoic acid-inducible gene I(RIG-I), Toll-like receptors (TLRs), and especially the cyclic GMP-AMP synthase-stimulator of IFN genes (cGAS-STING) pathway, which has been shown to promote liver injury. We postulated that DAP12 may promote liver mDC tolerogenicity by negatively regulating the cGAS-STING-IFN I signaling pathway.
Methods: Wild-type (WT) and DAP12 KO B6 mouse liver and spleen mDCs ($CD11b^+NK1.1^-CD11c^+$) were freshly-isolated and harvested after 4 hours culture in the absence or presence of 2,3-cGAMP or H-151(STING-specific inhibitor). Phenotypic analysis was performed by flow cytometry to characterize the expression of MHC II, CD80, CD86 and PD-L1. IFN-α and IFN-β mRNA transcripts and cytokine levels in supernatants were quantified using q-PCR and ELISA respectively. The activation of p-STING/STING and its downstream targets p-TBK1/TBK1, p-IRF3/IRF3 were probed by western blot. T cell allostimulatory function of the mDC was assessed by CFSE-MLR.
Results: DAP12 KO increased p-STING, p-TBK1 and p-IRF3 expression, enhanced MHC II and co-stimulatory molecule expression, but decreased co-inhibitory PD-L1 in the presence or absence of 2,3-cGAMP by both liver and spleen mDC. In addition, IFN-α and IFN-β mRNA levels and secretion in supernatants were augmented. DAP12 KO liver and spleen mDC showed superior ability to stimulate allogeneic T cell proliferation, while H-151-treated DAP12 KO mDCs exhibited reduced p-STING, p-TBK1 and p-IRF3 expression, lower MHC II and co-stimulatory molecule expression, but increased co-inhibitory PD-L1, impaired IFN-α and IFN-β expression and secretion with 2,3-cGAMP exposure in both liver and spleen mDC. The enhanced allogeneic T cell stimulatory ability of DAP12 KO liver and spleen mDC was reversed by STING inhibition via H-151. Notably, the elevation in STING-IFN-I activation in DAP12 KO compared with WT cells was much higher in liver mDC than in spleen mDC.
Conclusions: DAP12 may promote liver DC tolerogenicity by negatively regulating the STING-IFN I pathway.

Abstract# 514

Lung Transplant Recipients Developing Early DSAs are Characterized by a Shift Towards Memory B Cells Directly After Transplantation

S. Christoph[1], A. Hitz[1], R. Bellmàs Sanz[1], J. Kühne[1], B. Wiegmann[2], F. Ius[2], J. Salman[2], E. Chichelnitskiy[1], T. Siemeni[2], W. Sommer[3], A. Haverich[2], G. Warnecke[3], C. Falk[1], *[1]Institute of Transplant Immunology, MHH, Hannover, Germany, [2]Department of Cardiothoracic, Transplant and Vascular Surgery, MHH, Hannover, Germany, [3]Department of Cardiac Surgery, University Hospital Heidelberg, Heidelberg, Germany*
Purpose: After lung transplantation (LTx), the development of early donor HLA-specific antibodies (eDSA) is associated with antibody-mediated rejection (AMR) and poor graft survival. Since 2013, patients with eDSA within the first month after LTx are treated with IgA/IgM enriched intravenous immunoglobulins (IgGAM), occasionally with anti-CD20 antibody (Rituximab). We hypothesise that the composition of naïve and memory B cell subsets differs between eDSA-positive and negative patients already before and directly after LTx.
Methods: In a pilot study of 58 LTx recipients, B cell subsets were analysed by flow cytometry using CD19, CD20, IgD, CD24, CD27antibodies pre, post (T0), 24 hours (T24) and 3 weeks after LTx. The proportions of B cell subsets were compared between eDSA-positive (n=13, 22,4%) and -negative (n=45, 77,6%) patients at discharge three weeks after transplantation.
Results: Within the first 24h, patients without eDSAs showed a significant increase in IgD+ CD27- naïve B cells ($p<0,0001$) accompanied by a significant decrease in IgD- CD27+ memory B cells, independently of the presence of eDSA (all, $p<0,0007$). Of note, eDSA-positive patients constantly showed higher frequencies of $IgD^+CD27^-CD24^{hi}$ naïve and lower frequencies of $IgD^-CD27^-CD24^{lo}$ memory B cell subsets compared to eDSA-negative patients. A transient increase in IgD^+CD27^+ switch memory B cells was detected at T0 in both groups, returning to baseline levels already at T24.
Conclusions: Lung transplant recipients show remarkable dynamics of naïve, memory and switch memory B cells within the first 24 hours characterized by a shift from naïve towards memory B cells, which was more pronounced in the eDSA group. Based on these preliminary data, a refined B cell monitoring may be able to identify patients with a higher risk for eDSA development in the future and pave the way to more specific treatment options to prevent eDSA.

Abstract# 515

Autoantibodies Against Ro/SS-A, CENP-B, and La/SS-B are Increased in Patients with Kidney Allograft Antibody-mediated Rejection

S. Clotet-Freixas[1], M. Kotlyar[2], C. M. McEvoy[1], C. Pastrello[2], S. Rodríguez-Ramírez[1], S. Farkona[1], H. Cardinal[3], M. Dieudé[3], M. Hébert[3], Y. Li[1], O. Famure[1], P. Chen[1], S. Kim[1], E. Chan[4], I. Jurisica[2], R. John[1], A. Chruscinski[1], A. Konvalinka[1], *[1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [2]Krembil Research Institute, University Health Network, Toronto, ON, Canada, [3]Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Montreal, QC, Canada, [4]Department of Medicine, Division of Nephrology, University Health Network, Toronto, ON, Canada*
Purpose: Antibody-mediated rejection (AMR) causes >50% of late kidney graft losses. Although donor-specific antibodies (DSA) against HLA cause AMR, antibodies against non-HLA antigens are also linked to rejection. Identifying key non-HLA antibodies will improve our understanding of antibody-mediated injury.
Methods: We analyzed non-HLA antibodies using protein arrays in sera from 91 kidney transplant patients with AMR, mixed rejection, acute cellular rejection (ACR),

or acute tubular necrosis (ATN). IgM and IgG antibodies against 134 non-HLA antigens were measured pre-transplant and at the time of biopsy-proven diagnosis. Findings were validated in 60 kidney transplant patients from an independent cohort.
Results: Seventeen non-HLA antibodies were significantly increased (P<0.05) in AMR/mixed rejection compared to ACR or ATN pre-transplant, and 9 at diagnosis. AMR/mixed cases showed significantly increased pre-transplant levels of IgG anti-Ro/SS-A and anti-CENP-B, compared to ACR. Together with IgM anti-CENP-B and anti-La/SS-B, these antibodies were also significantly increased in AMR/mixed rejection at diagnosis. Increased IgG anti-Ro/SS-A and anti-CENP-B pre-transplant and at diagnosis, and IgM anti-La/SS-B at diagnosis, were associated with the presence of microvascular lesions and class-II DSA (P<0.05). Significantly increased IgG anti-Ro/SS-A in AMR/mixed compared to ACR (P=0.01), and numerically increased IgM anti-CENP-B (P=0.05) and anti-La/SS-B (P=0.06), were validated in the independent cohort.
Conclusions: This is the first study that implicates autoantibodies against Ro/SS-A and CENP-B in AMR. These non-HLA antibodies may participate in the crosstalk between autoimmunity and alloimmunity in kidney AMR.

Abstract# 516

Properties of Regulatory B Cells Suppressing B Cells

Q. Fu[1], K. Lee[2], K. Deng[2], G. Huai[2], C. Rickert[2], H. Yang[1], C. LeGuern[2], S. Deng[1], J. F. Markmann[2], *[1]Organ Transplantation Center, Sichuan Provincial People's Hospital, University of Electronic Sciences and Technology of China, Chengdu, China, [2]Center for Transplantation Sciences, MGH, Boston, MA*

Purpose: Our previous study showed that TLR-Bregs, regulatory B cells generated *in vitro* through TLR activation, suppressed naïve B cell proliferation triggered by a mitogen (LPS-B cells). The mechanism underlying Breg suppression is presently unknown. The present study on batch and single-cell RNAseq analyses of suppressed LPS-B cells and suppressive TLR Bregs provide important insights on pathways associated with suppression.
Methods: TLR-Bregs were generated from enriched C57BL/6 splenic CD19+B cells cultured in the presence of CpG ODN1668 for 3 days (CpG-B cells), followed by the addition of LPS (10ug/ml), PMA (50ng/ml), and ionomycin (1ug/ml) for the last 5 hours. Suppression was measured in 3 day-cocultures of TLR-Bregs and naïve B cells stimulated with LPS (LPS-B cells). B cell proliferation/ differentiation was assessed by flow cytometry. RNAseq analysis was performed on naive B, CpG-B cells, and TLR-Bregs. RNA-Seq data of the LPS-B cells (LPS-B24h and LPS-B72h) and TLR-Bregs were analyzed using R programming (version 3.6.3). Gene Ontology (GO) was used to perform enrichment analysis on differentially expressed genes (DEGs).
Results: Co-DEGs among those LPS-B cells identified 23 and 6 genes with up or down-regulation of expression among LPS-B72h, LPS-B24h, and naive B cells. Among those 29 genes, 17 were also differentially expressed in TLR-Bregs in comparison with CpG-B and naive B cells. Go pathway analysis for these 17 co-genes found that Il10, Prdm1, and Il2ra (CD25) were positively enriched in B cell proliferation. Among those three genes, Il10 and Il2ra both increased in LPS-B cells and TLR-Bregs while Prdm1 increased in LPS-B cells and decreased in TLR-Bregs. Flow cytometry revealed that TLR-Bregs, but not CpG-B cells, inhibited Prdm1 expression. The scRNA-seq analysis suggested clusters 0, 2, 5, and 7 were proliferated B cells after LPS stimulation (Figure 1). Clusters 0 and 5 also highly-expressed Prdm1 and Sdc1, which were identified as plasma cells. These combined results indicated that TLR-Bregs suppressed clusters 0, 2, 5, and 7 and eventually suppressed proliferation and differentiation of LPS-B cells.
Conclusions: TLR-Bregs can suppress the proliferation and differentiation of naïve B cells induced by LPS. The suppression of Prdm1 may indicate that the mechanism for which TLR-Bregs suppress other B cells lies in the Prdm1-relevant pathway.

Abstract# 517

Autoimmune Responses to DNA Topoisomerase I Exacerbate Renal Allograft Injury

V. Gorbacheva, R. Fan, S. Miyairi, W. Baldwin, R. Fairchild, A. Valujskikh, *Inflammation and Immunity, Cleveland Clinic, Cleveland, OH*

Purpose: Multiple clinical and pre-clinical studies describe correlations between pre-existing or *de novo* autoimmune responses and poor transplant outcome. We have previously reported that following renal transplantation, mouse recipients containing donor-reactive memory CD4 T cells rapidly develop donor specific alloantibody (DSA) causing acute antibody-mediated rejection (AMR). Inhibition of DSA production prevented acute AMR but the allografts in these recipients developed signs of chronic tissue injury at later time points. The goal of this study was to test whether donor-reactive memory T cells also induce generation of autoantibodies and investigate the relevance of these autoantibodies to renal tissue injury.
Methods: C57BL/6 (B6, H-2^b) recipients containing donor-reactive memory T cells were transplanted with BALB/c (H-2^d) renal allografts. Recipient sera were collected at d. 7 posttransplant and screened for reactivity to potential autoantigen epitopes using PEPperCHIP Autoimmune Epitope Microarray. Peptide TI-$I_{205-219}$ representing an identified DNA topoisomerase I (TI-I) 205-219 epitope was custom-synthesized. B6 mice immunized with TI-$I_{205-219}$ (3 biweekly injections of 100μg TI-$I_{205-219}$/CFA s.c.) were tested in a model of bilateral renal warm ischemia or used as recipients of BALB/c renal allografts.
Results: DNA topoisomerase I peptide TI-$I_{205-219}$ was identified as the most prominent epitope in sensitized renal allograft recipients. Anti-TI-$I_{205-219}$ antibodies were induced after transplantation of BALB/c kidney allografts into non-sensitized B6.WT but not B6.TCRβ-/- recipients indicating that T cell help is required for autoantibody production. Furthermore, the level of anti-TI-$I_{205-219}$ autoantibodies was further increased in sensitized recipients.Immunization with TI-$I_{205-219}$ resulted in the generation of TI-$I_{205-219}$ IgG autoantibody and markedly exacerbated renal pathology after 25 min of bilateral warm kidney ischemia followed by reperfusion. TI-$I_{205-219}$/CFA immunization resulted in rapid rejection in 10/12 kidney allograft recipients (MST of

13.5 d) whereas only 2/6 CFA-immunized controls rejected by d. 16 posttransplant. TI-$I_{205-219}$/CFA immunization increased frequencies of donor BALB/c-reactive T cells but not serum class I and class II DSA levels at the time of rejection.

Conclusions: Our data identify DNA topoisomerase I as a novel self-antigen target and suggest complex interplay between auto- and alloreactive T cells and antibodies in the context of kidney transplantation.

Abstract# 518

Donor-specific Regulatory B Cells Prolong Skin Graft Survival by Preventing the Proliferation of Donor-specific CD4 Helper but Not of CD8 Effector T Cells

G. Huai[1], K. Lee[2], K. Deng[2], Q. Fu[1], C. G. Rickert[2], S. Deng[1], C. LeGuern[2], J. F. Markmann[2], *[1]Department of Organ Transplantation Center, Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chengdu, China, [2]Center for Transplantation Sciences, Massachusetts General Hospital, Harvard Medical School, Boston, MA*

Purpose: TLR-Bregs were defined by our group as B cells generated *in vitro*. They have demonstrated the ability to inhibit CD4 T cell proliferation. Since CD8 T cells are also major players in rejection of organ transplants, the present report explores the mechanisms by which TLR-Breg suppression may differentially affects CD4 and CD8 T cells in a transplantation setting.

Methods: B6 TLR-Bregs and OB1 TLR-Bregs were generated from B cells isolated from C57BL/6 and transgenic OB1 mice (B cell receptor specific to ovalbumin, OVA). *In vitro* MLR was set up in co-culture of CFSE-labeled $CD8^+$ T cells (OVA-specific) as responders, irradiated OVA splenic cells as stimulators, and OB1 TLR-Bregs as suppressors. For *in vivo* suppression experiments, CD8 T cells were adoptively transferred to B6 underwent OVA skin graft, with or without B6 or OB1 TLR-Bregs. Cells from draining lymph nodes (DLN), non-draining lymph nodes (N-DLN), and spleen (SP) were harvested and analyzed by flow cytometry. The combination of anti-CD8 mAb and OB1 TLR-Bregs were administrated to check skin graft survival.

Results: *In vitro* assays showed that OB1 TLR-Bregs suppress $CD8^+$T cell proliferation and INF-γ production ($p<0.05$, vs control). In contrast to previous results showing that $CD4^+$ T cells were concentrated in DLN, $CD8^+$ T cells were not only found in the DLN, but also in the N-DLN and spleen (Figure 1). Suppression assays *in vivo* confirmed the inability of either B6 or OBI TLR-Bregs to inhibit $CD8^+$ T cell proliferation, positive controls of proliferation were at 79.9%±3.8% and had no significant difference with Bregs treatment (64.7%±17.3%, Figure 2). Importantly, the in vivo depletion of $CD8^+$T cells in mice treated with OB1 TLR-Bregs (61 days) did not significantly prolong graft survival than OB1 TLR-Bregs alone treatment (38 days).

Conclusions: The lack of TLR-Breg control over $CD8^+$ T cell proliferation may result from a more disperse lymphoid tissue distribution of these cells as compared to that of $CD4^+$T cells. Collectively, these data indicate that ex-vivo generated Bregs promote prolongation of graft survival, mainly by downregulating $CD4^+$ helper T cell proliferation, which in turn may curtail graft-specific CD8 reactivity. Additional studies will be required to identify potential therapeutic targets to improve graft survival.

Abstract# 519

In Vitro Generated Regulatory B Cells Induce $Cd4^+Cd25^+Foxp3^+$Tregs from $Cd4^+Cd25^-$T Cells via TGF-β

G. Huai[1], K. Lee[2], K. Deng[2], Q. Fu[1], C. G. Rickert[2], S. Deng[1], C. LeGuern[2], J. F. Markmann[2], *[1]Department of Organ Transplantation Center, Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chengdu, China, [2]Center for Transplantation Sciences, Massachusetts General Hospital, Harvard Medical School, Boston, MA*

Purpose: Our team previous study showed that TLR-Bregs, stimulated through TLR pathway *in vitro*, harbored regulatory properties by suppressing $CD4^+$ T cell proliferation and function *in vitro* and *in vivo*. These TLR-Bregs can also prolong skin graft survival. We describe here to explore TLR-Bregs function to induce Tregs and identify the mechanism of Tregs induction by TLR-Bregs.

Methods: OB1 TLR-Bregs were generated *in vitro* from B cells isolated from transgenic OB1 mice (B cell receptor specific to OVA). For Tregs induction by TLR-Bregs assay, C57BL/6 mice, transplanted with OVA skin, treated with or without OB1 TLR-Bregs. The $CD4^+Foxp3^+$ Tregs expression in draining lymph node (DLN) of recipient will be detected at day 14. To identify the mechanism of OB1 TLR-Bregs on Tregs induction, $CD4^+CD25^-$ T cells sorted from OT II mice spleen, and then adoptively transfer to the SCID mice underwent OVA skin graft. In the same line, the SCID mice would be administrated OB1 TLR-Bregs (BCR specific for OVA) alone or combine with anti-IL-10 antibody (250 ug/mice), anti-TGF-β antibody (200ug/mice) or isotype control (200ug/mice) every other day from day 0 to day 8. After 14 days, $CD4^+CD25^+Foxp3^+$ Tregs from DLN would be analyzed by flow cytometry.

Results: The results from Tregs induction by TLR-Bregs assay showed that, with OB1 TLR-Bregs treatment, the $CD4^+Foxp3^+$ Tregs expression is highly increased ($p<0.05$, vs control). The experiment of Tregs generation in SCID mice revealed significant upregulation in $CD4^+CD25^+Foxp3^+$Tregs expression with OB1 TLR-Bregs treatment (3.7%±1.6%, $p<0.05$, vs no B cells). In the same time, when SCID mice administrated with the combination of OB1 TLR-Bregs and anti-TGF-β antibody, $CD4^+CD25^+Foxp3^+$Tregs expression would be decreased significantly (1.6%±o.4%, $p<0.05$, vs OB1 TLR-B cells). However, depletion of IL-10 in mice treated with OB1 TLR-Bregs showed no big difference with OB1 TLR-Bregs alone.

Conclusions: OBI TLR-Bregs can convert the $CD4^+CD25^-$ T cells to $CD4^+CD25^+Foxp3^+$Tregs, and only the ablation of the TGF-β antibody block Tregs induction, that attributes to TLR-Breg cells induce Foxp3 expression of $CD4^+CD25^-$ T cells through TGF-β but not IL-10. Tregs induced by TLR-Bregs is related to prolong the skin graft survival. Therefore, TGF-β dependent tolerance induction by TLR-Bregs will be explored in organ transplantation model.

Abstract# 520

Quantifying Hidden Sensitization: HLA-reactive Memory B Cells in the Spleens of Sensitized Women

J. T. Killian[1], J. A. Houp[1], A. Nellore[2], R. G. King[3], P. M. Porrett[1], F. E. Lund[3], *[1]Department of Surgery, University of Alabama at Birmingham School of Medicine, Birmingham, AL, [2]Department of Medicine, University of Alabama at Birmingham School of Medicine, Birmingham, AL, [3]Department of Microbiology, University of Alabama at Birmingham School of Medicine, Birmingham, AL*

Purpose: Measurement of circulating anti-HLA antibody (anti-HLA-Ab) in transplant candidates and recipients is required for successful organ transplantation. However, serum Ab measurement alone likely underestimates the full spectrum of HLA reactivity in sensitized individuals, as memory B cells (Bmems) which target HLA specificities distinct from anti-HLA-Abs may also be generated during a sensitization event. While this "hidden" sensitization (HS) may predispose patients to an early anamnestic response posttransplant, the prevalence of HS is unknown as studies of HLA-reactive Bmems have relied on peripheral blood samples with a limited number of HLA-reactive Bmems. We aimed to improve our understanding of the prevalence and specificity of HS by analyzing Bmems in human spleens.

Methods: IgG+ Bmems were purified from the spleens of six sensitized female organ donors. Cells, which were activated with IL-2, IL-21, and R848, secreted Abs into the supernatants (SNs) that reflected the Bmem specificities. Serum and SN anti-HLA-Abs were identified using a Luminex assay. The number of HLA specificities was compared between serum and SN for each donor. HLA specificities present only in SNs were classified as "hidden" (teal bars in Fig. 1).

Results: HS was detected in three of six females, and detection markedly improved in samples with greater than 500,000 Bmems (Fig. 1, Group B). Among samples with fewer than 500,000 activated Bmems (Group A), SNs contained an average of 19% of the serum specificities (0%, 17%, and 39% for the three donors respectively), while samples with greater than 500,000 activated Bmems (Group B) produced antibodies that contained an average of 64% of the serum specificities (44%, 80%, and 85% for the three donors respectively). HS was detected in two of three donors in Group B.

Conclusions: Using serum anti-HLA-Abs alone underestimates the breadth of sensitization. By analyzing the spleen, we were able to increase the number of Bmems sampled by over 100-fold relative to peripheral blood-based studies. Compared to those studies, we detected a higher percentage of serum specificities contained in SNs. HS was also detected more frequently. This approach may improve the sensitivity for detecting HLA-reactive Bmems and for developing a more comprehensive picture of HLA-reactive B cell memory.

Abstract# 521

Suppression of T Cell Proliferation by Activated Nonhuman Primate B Cells

K. Lee, K. Deng, G. Huai, F. Qiang, C. Rickert, J. Lei, C. Leguern, J. Markmann, *Massachusetts General Hospital, Boston, MA*

Purpose: We previously generated Toll-like receptor (TLR)-activated B cells in rodent settings. These B cells can suppress T cell proliferation via *in vitro* mixed lymphocytes reaction and promote allograft tolerance as Regulatory B cells (Bregs). A continuous effort toward Bregs drove us to generate TLR-activated B cells in Nonhuman primates using the same protocol in the murine model. In this study, we evaluated the efficacy of their phenotype, function, and mechanism to suppress T cell responses.

Methods: Purified splenic NHP B cells were activated with CpG ODN 2006-5G for 3 days with the addition of LPS, PMA, and ionomycin for the last 5 hours. They were then harvested and co-cultured with CFSE-labeled autologous T cells stimulated with polyclonal CD3/CD28 beads or PHA. On day 4, proliferation was measured by flow cytometry. In some cultures, anti-PD1, or anti-GzmB was added to evaluate their role in suppressing T cell proliferation.

Results: The majority of CpG/LPI-NHP B cells had immature phenotypes, CD20+CD21+CD27-IgM+ on surface. In *in vitro* experiment, they effectively suppressed CD4+ and CD8+ T cell proliferation and reduced their viability upon stimulation, while B cells with only CpG activation did not. The CpG/LPI-NHP B cells expressed higher levels of LAP, a surrogate marker for TGF-β, and programmed death (PD1), but not expressed a higher level of IL-10 compared to naïve NHP B cells. Instead, it seemed that Granzyme B (GzmB) was instrumental to the suppressive effect because the blockade of GzmB increased the proliferation in the coculture.

Conclusions: We have successfully generated NHP Bregs with *in vitro* suppressive capacity toward T cell responses. Here we show for the first time that CpG-activated NHP B cells exert regulatory function. Our studies suggest that Bregs may provide a great option for regulatory cell-based therapy. We are pursuing the translational potential of Bregs in a large animal model by evaluating their regulatory function i*n vivo*.

Abstract# 522

Targeting Il-21 Receptor Shifts Tfh/tfr Balance and Amelioratechronic Antibody Mediated Rejection

Y. Nian, Z. Xiong, J. Zhao, Y. Fu, *Tianjin First Central Hospital, Tianjin, China*

Purpose: Donor specific antibody (DSA) plays a central role in chronic kidney allograft injury. As a trigger of humoral alloimmune response, follicular T helper cells(Tfh) promote DSA generation, while T-Follicular regulatory cells(Tfr) inhibit antibody production by suppressing Tfh and B cells. The key cytokine IL-21 exerts distinct effect on Tfh and Tfr. Here we studied whether blocking IL-21 by monoclonal IL-21R antibody changes the Tfh/Tfr balance and inhibits dnDSA generation.

Methods: First, we investigated the impact of αIL-21R on Tfh and Tfr in in-vitro conditioned culture. Naïve CD4+ T cells were isolated from 3 months old C57BL6 mouse and cultured in Tfh condition with αIL-21R or isotype IgG. Proliferation and differentiation were evaluated by CFSE dilution and BCL-6, ICOS, PD-1 expression with flow cytometry. For further in-vivo investigation, a fully mismatch skin transplantation model was utilized to trigger the humoral alloimmune response. For further in-vivo investigation, a fully mismatch skin transplantation model was utilized to trigger the humoral alloimmune response.

Results: . αIL-21R inhibits Tfh proliferation and differentiation significantly. By contrast, in modified Treg condition (conventional Treg condition plus IL-6), cell proliferation and Bcl-6 expression were not inhibited by αIL-21R. Notably, Inhibition of IL-21 on Tfr proliferation can be reversed by αIL-21R. Mechanistically, Akt signal pathway was significantly up-regulated and inhibited by αIL-21R in Tfh, while remained in constant quiescent level in Tfr regardless of administration of αIL-21R. In consistent with in-vitro data, flow cytometry and immunofluorescence revealed reduced Tfh/Tfr ratio in recipients treated with αIL-21R. Germinal center response was evaluated with lectin histochemistry. αIL-21R inhibited the formation of germinal center significantly. Most importantly, dnDSA level in different time points after transplantation revealed a significant inhibition of αIL-21R on dnDSA generation.

Conclusions: In summary, our results demonstrate that monoclonal αIL-21R shifts Tfh/Tfr balance towards dnDSA reduction and ameliorates chronic injury by suppressing Tfh and blocking the impact of IL-21 on Tfr. The αIL-21R might, therefore, be a useful treatment in organ transplantation to prevent chronic antibody mediated rejection.

Abstract# 523

Antibodies to Hla Molecules Lead to Induction and Release of Circulating Exosomes with Lung Self-Antigens

R. Ravichandran, M. Smith, R. Bremner, T. Mohanakumar, *St. Joseph's Hospital and Medical Center, Phoenix, AZ*

Purpose: Antibodies (Abs) to human leukocyte antigen (HLA) (anti-HLA) can injure allograft by complement-dependent/independent mechanisms. Crosslinking of HLA-class I with Abs associate with integrin β4 and Src/FAK signaling pathway in endothelial cells and induction of endoplasmic reticulum (ER) stress. We sought to determine whether anti-HLA both class I and II can induce circulating exosomes from human airway epithelial cells *in vitro* and mechanism involved in exosome release.

Methods: Human airway epithelial cell line (KCC266) was incubated with anti-HLA-A2 or high panel reactive sera (ie, anti-HLA), W6/32 (anti-HLA class I), anti-HLA class II (DR and DQ) for 24 hours. Exosomes were isolated by ultracentrifugation; size was defined by Nanosight NS300. Western blot was performed to determine lung self-antigens (Kα1Tubulin, Collagen V). Ability of anti-HLA to induce stress kinases and influence of exosome inhibitor GW4869 (20μM) in exosome release were determined.

Results: Airway epithelial cells incubated with anti-HLA demonstrated induction of exosomes (<200 nm) containing self-antigen (Collagen V) (fold change: anti-A2, 3±1; anti-HLA, 2±0.5). Anti-HLA class I and II also induced exosomes with self-antigens (Collagen V (W6/32, 3±0.4; Abs to HLA-DR, 3±0.5; Abs to HLA-DQ, 2±0.6, and Kα1Tubulin (W6/32, 2±0.6; Abs to HLA-DR, 2.±0.4 Abs to HLA-DQ, 1.9±0.3). Anti-HLA induced ER stress markers in airway epithelial cells; PKR-like endoplasmic reticulum kinase (1.52±0.1) and eukaryotic translation initiation factor α (1.8±0.3). Anti-HLA class I (W6/32) also induced ER stress markers in airway epithelial cells; PKR-like endoplasmic reticulum kinase (2±0.8) and eukaryotic translation initiation factor α (2±0.4). Exosome release from airway epithelial cells was inhibited by GW4869 (20μM; 82±8%) but did not abrogate ER stress. Anti-HLA class I upregulated integrin β4 /FAK/SRC pathway and ER stress in AEC and lead to exosome release.

Conclusions: Ligation of HLA molecules (class I and II HLA-DR, DQ) on human airway epithelial cell line by Abs specific to HLA induced exosomes with lung self-antigens (Kα1Tubulin, Collagen V), and ER stress *in vitro*. Anti-HLA class I ligation induced integrin β4 signaling by FAK/SRC pathway and ER stress which lead to release of exosomes from airway epithelial cells. We, therefore, present a new mechanism by which anti-HLA-induced stress of the transplanted organ can induce exosome release with self-antigens, contributing to the pathogenesis of rejection of the allograft.

Abstract# 524

Development of a Rat Model of Antibody-Mediated Rejection After Liver Transplantation

T. Tajima, K. Hata, J. Kusakabe, H. Miyauchi, S. Uemoto, *Dept. of Surgery, Div. of HBP Surgery & Transplantation, Kyoto University Graduate School of Medicine, Kyoto, Japan*

Purpose: Antibody-mediated rejection (AMR) is a refractory rejection after donor-specific antibody (DSA)-positive or ABO blood-type incompatible liver transplantation (LT), due at least in part to lacking a standardized rodent model of AMR.

Methods: Orthotopic LT was performed from male Dark Agouti rats (DA, 240-260g, donors) to male Lewis rats (LEW, 280-300g, recipients), served as non-sensitized controls (Group-NS). In pre-sensitized group (Group-PS), LEW were pre-sensitized by a preceding skin transplantat (2 x 2 cm^2) from DA with subcutaneous aluminum adjuvant 4-6 weeks prior to LT.Tacrolimus was daily administered (0.1 mg/kg/day) after LT until sacrifice to suppress cellular rejections. Blood and liver tissues were sampled on post-transplant day (PTD)-1, -3, and -7 (n =5 each). Both IgG- and IgM-DSA titers in recipient sera were determined by flow cytometry.

Results: AST, ALT, ALP, total bile-acid (TBA), and bilirubin were all significantly higher in Group-PS than in Group-NS (P<0.01). In particular, biliary damage markers, i.e. ALP, TBA, and bilirubin, were significantly deteriorated in Group-PS than in -NS on PTD-7 (P <0.001), followed by thrombocytopenia (P <0.05) and aggravated PT-INR (P <0.05). Histopathological grading (P <0.001) and C4d scores (P <0.001) were also significantly deteriorated in Group-PS than in -NS on PTD-7. As underlying mechanisms, we demonstrated significantly upregulated IgG- and IgM-DSA titers (P<0.001 and <0.05, respectively), accompanied with significantly-more infiltrated plasma cells to transplanted liver tissues (P <0.001) in Group-PS than in -NS on PTD-7.

Conclusions: By a preceding skin sensitization with post-transplant tacrolimus, we developed a rat AMR model after LT that satisfies the Banff criteria for AMR diagnosis.

Abstract# 525

A Novel Mouse Model of Cardiac Allograft Vasculopathy

H. Tsuda[1], E. Reed[2], W. Baldwin[1], R. Fairchild[1], *[1]Inflammation and Immunity, Cleveland Clinic, Cleveland, OH, [2]Pathology and Laboratory Medicine, University of California, Los Angeles, CA*

Purpose: Cardiac allograft vasculopathy (CAV) is a major long-term complication of heart transplantation and the presence of donor specific antibodies (DSA) is associated with an increased incidence of CAV in heart transplant recipients. However, mechanisms underlying development and progression of the pathology remain poorly understood. We previously have reported that MHC-mismatched A/J cardiac allografts in B6.CCR5-/- recipients were acutely rejected within 7-10 days with low T cell infiltration, but intense deposition of C4d in the large vessels and capillaries of the graft, as well as high serum titers of DSA, characteristics observed in antibody-mediated rejection (AMR).

Methods: In this study, we utilized this AMR model to investigate mechanisms of CAV development within the grafts. To test this, we transplanted A/J allografts into B6.CCR5-/- CD8 -/- mice and treated recipients with a low dose of anti-CD4 mAb on days 0, 2 and 7.

Results: While the mild inhibition of CD4 T cells extended the survival of allografts, the grafts developed CAV with intense C4d deposition in the myocardial capillaries accompanied by macrophage infiltration on days 14 post-transplant. Consistent with this, DSA titers were also much higher than in B6.CD8-/- recipients. Interestingly, development of CAV was absent in semi-allogeneic (A/J x B6) F1 grafts which inhibit recipient NK cell activity.

Conclusions: In conclusion, we have developed a novel antibody mediated CAV model using CCR5-/- CD8-/- mice as allograft recipients that will facilitate an understanding of molecular and cellular mechanisms of CAV.

Abstract# 526

Iguratimod Prevents Antibody-mediated Rejection by Regulating Germinal Center Formation and Antibody Production

H. Zhang, A. Chandraker, P. Sage, N. Murakami, *Transplantation Research Center, Brigham and Women's Hospital, Boston, MA*

Purpose: Antibody-mediated rejection (ABMR) is a major cause of chronic renal allograft failure without effective treatment, and developing a novel therapy is an urgent need. Here, we hypothesized that Iguratimod (IGU), an immunomodulator that has been approved for treating rheumatoid arthritis, can prevent the ABMR in kidney transplantation.

Methods: Human PBMCs were stimulated with anti-CD3 and anti-CD28 with and without iguratimod as well as were cultured for 5 days in the presence of IL-2 and R848, with and without various concentration of iguratimod, or bortezomib (BTZ, positive control) in vitro to test the effect of iguratimod on cell proliferation and whether iguratimod affects human B cell differentiation to antibody-stimulating cells (ASCs). To dissect the exact mechanism, we immunized C57BL/6 mice with NP-OVA/CFA, pre- and post-treated the IGU (30 mg/kg/d, PO, from day -7 to day 10), isolated serum and draining lymph nodes (dLNs) for analysis. Using a sequential skin and kidney transplantation ABMR model in rat to explore its function in organ transplant.

Results: We found iguratimod did not affect survival of T and B cells after stimulation for 5 days. In the absence of iguratimod, about 15% of B cells differentiated into ASCs (CD19+CD38+CD27+, (Figure A)). Iguratimod inhibited B cell differentiation

to ASCs in a dose-dependent manner (Figure A, right). A clear reduction was shown in the frequency of CD19+FAS+GL7+ germinal center (GC) B cells in the IGU group (Figure B). IGU attenuated IgG1+ class-switched B cells, IgG1+CD38+ memory-like B cells and NP-specific IgG and IgM in serum, suggesting that IGU inhibited B cell differentiation and proliferation, and antigen-specific antibody responses by inhibiting early GC responses. In B cells isolated from dLN, NF-KB, one of the key transcription factors regulating GC formation, was inhibited by IGU in dLNs, which is consistent with OVA stimulation data (Figure C). This suggests that IGU inhibited GC formation probably by regulating the NF-KB pathway. Finally, in ABMR rat model, we found IGU attenuated ABMR and prolonged the graft survival, with histological evidence of ameliorated glomerulitis and peritubular capillaritis, less C4d deposition in kidney grafts, and lower titer of DSA in serum.

Conclusions: IGU specifically inhibited GC formation and thus attenuated DSA formation without impacting T cell survival. IGU can be a potential new immunosuppressant to prevent and attenuate ABMR in kidney transplantation (Figure D).

Abstract# 527

Transgenic Beta-cell Cxcl12 Expression and Stem Cell Mobilization Synergize to Suppress Type 1 Diabetes

D. A. Alagpulinsa, A. Jajoo, M. H. Chapin II, M. C. Poznansky, *Vaccine & Immunotherapy Center, Massachusetts General Hospital and Harvard Medical School, Boston, MA*

Purpose: Hematopoietic stem and progenitor cells (HSPCs) and regulatory T cells (Tregs) highly express CXCR4, the receptor for the CXCL12 chemokine. This keeps them predominantly anchored to the bone marrow (BM) where CXCL12 is constitutively expressed at high levels. HSPCs and Tregs possess superior immunoregulatory properties and infusion of autologous HSPCs and Tregs is intensively investigated as a treatment for type 1 diabetes (T1D), which results from autoimmune-mediated destruction of insulin-producing β cells. β cells also express CXCR4 and CXCL12 exerts growth and pro-survival effects on them and can repel autoreactive T cells from islets. We hypothesized that CXCL12 could be exploited to recruit and retain endogenous HSPCs and Tregs in the islets to ameliorate autoimmune destruction of β cells and support β-cell survival and growth (Figure 1).

Methods: We evaluated this hypothesis in NOD mice that spontaneously develop autoimmune diabetes.

Results: CXCL12 levels were 3-fold higher in the BM of autoimmune diabetic NOD mice compared with age matched non-diabetic C57BL/6 mice. In reverse, the activity of DPP4, an exopeptidase that cleaves and inactivates the chemotactic effects of CXCL12, was ~2-fold lower in the BM of these NOD mice compared with their age matched C57BL/6 mice. This dysregulation of CXCL12 could contribute to polarized BM retention and impaired peripheral mobilization of HSPCs and Tregs in T1D. We showed that ectopic β-cell-specific expression of CXCL12 transgene under the control of the rat insulin promoter using a recombinant adeno-associated virus vector ($p<0.05$) and peripheral mobilization of HSPCs using granulocyte-colony stimulating factor plus DPP4 inhibitor treatment ($p<0.06$) delay autoimmune diabetes onset in NOD mice. Intriguingly, ectopic β-cell expression of CXCL12 synergized with peripheral mobilization to suppress autoimmune diabetes compared with either treatment alone ($p<0.02$; $n\geq10$ per group). This synergy was characterized by increased numbers of circulating HSPCs, reduced insulitis, improved glucose tolerance and enhanced β-cell mass.

Conclusions: Our findings demonstrate proof-of-concept of a novel "pushing" and "pulling" approach for T1D treatment.

Figure 1. A model for exploiting CXCL12 to recruit and retain HSPCs and Tregs as well as other CXCR4-expressing cells (mesenchymal stem cells, MSCs; endothelial progenitor cells, EPCs) in the islets.

Abstract# 528

Versatile Strategy to Enhance Nanomedicine Delivery to Graft Endothelial Cells

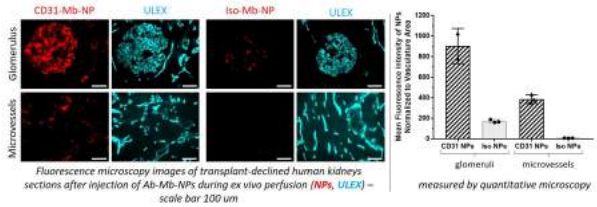
C. Albert[1], L. G. Bracaglia[1], A. Koide[2], J. DiRito[1], T. Lysyy[1], C. Edwards[1], J. T. Langford[1], D. Haakinson[1], S. A. Hosgood[3], M. L. Nicholson[3], J. S. Pober[1], W. M. Saltzman[1], S. Kiode[2], G. Tietjen[1], *[1]Yale University, new haven, CT, [2]Perlmutter Cancer Center, New York University, Langone Medical Center, New York, NY, [3]University of Cambridge, Cambridge, United Kingdom*

Purpose: Efficient delivery of therapeutics to graft endothelial cells (EC) can potentially render organs more resistant to injury, improving clinical outcomes. Specific targeting of polymeric nanoparticles (NPs) during *ex vivo* machine perfusion prior to transplant can allow both sustained delivery and increased local concentration of an encapsulated therapeutic. Despite ready access, effective retention by ECs lining graft vessels remains as a significant hurdle. Here we describe a new targeting approach based on oriented presentation of a targeting antibody using a linker called a "monobody" (Mb).

Methods: Mbs are synthetic binding proteins with a unique cysteine engineered to enable site-specific conjugation to NPs through thiol chemistry. Specific Mbs can potently and selectively bind to the Fc region of a targeting antibody (Ab), forming Ab-Mb-NP conjugates. We used flow cytometry and quantitative fluorescence microscopy of dye-loaded NPs to measure efficiency of binding to ECs in cell culture and in ex-vivo perfusion systems of single vessels and of transplant-declined human kidneys.

Results: Ab-Mb-NPs showed up to a 1000-fold enhancement of binding *in vitro* under flow compared to EDC-NHS conjugated Ab-NPs used in our prior work. This is likely due to a higher number of Ab attached and a better control of Ab orientation leading to high retention of antibody function. In the first transplant-declined human kidneys enrolled in the study, the targeted Ab-Mb-NPs bound specifically to the endothelial cells covering ~40% of the microvessels and ~70% of the glomeruli vasculature area. In addition, the Mb approach is readily adaptable to different NP compositions or conjugation of different Abs of the same species/isotype without re-engineering as is necessary with EDC/NHS conjugation. For example, we easily changed the polymer used to formulate the NPs (poly(lactic acid)-poly(ethylene glycol) [PLA-PEG] or poly(amine-co-ester) [PACE]). We also easily changed the targeted molecule (CD31 or ICAM2) or the species of the targeted molecule (human or pig) using identical conditions for conjugation.

Conclusions: Mb-coupled conjugation can both simplify and enhance the use of nanomaterials to target graft ECs, opening opportunities to efficiently deliver therapeutics prior to transplantation.



Fluorescence microscopy images of transplant-declined human kidneys sections after injection of Ab-Mb-NPs during ex vivo perfusion (NPs, ULEX) – scale bar 100 um

measured by quantitative microscopy

Abstract# 529

Single Cell RNA Sequencing Reveals a Global Increase in Inflammatory Gene Signature Following Normothermic Ex Vivo Liver Perfusion

K. Carlson, J. Pavan-Guimaraes, B. Verhoven, J. Verhagen, F. Najmabadi, D. P. Al-Adra, *Surgery, University of Wisconsin, Madison, WI*

Purpose: Normothermic *ex vivo* liver perfusion (NEVLP) provides an exciting system for improved organ preservation and optimized therapeutic agent delivery to a donor liver prior to transplantation. However, previous studies have shown examples of the inherent inflammatory nature of machine perfusion, including production of damage-associated molecular patterns and secretion of pro-inflammatory cytokines. Further characterization of the inflammatory processes induced by NEVLP are required to determine the optimal pathways to target with immunomodulatory therapies. Using single-cell RNA sequencing, we comprehensively characterized the inflammatory signatures of liver-resident immune cells following NEVLP.

Methods: Rat livers were procured and divided randomly into a naïve group or an NEVLP at 37°C for 4 hours group. We isolated non-parenchymal cells, and celll sorted for live cells. Single cell transcriptomic profiling of 12,259 total cells across two experimental conditions was generated using the 10x Genomics NextGEM Single Cell 3' (v3.1) assay. Libraries were sequenced on an Illumina NovaSeq6000 sequencer targeting an average depth of 70,000 reads/cell.

Results: NEVLP induced expression of an inflammatory gene signature in T-cells, dendritic cells, and several macrophage subpopulations in comparison to naïve controls (**Fig. 1**). An increase in expression of inflammatory mediators chemokine (C motif) ligand (Xcl1), OX40 receptor (Tnfrsf4), interferon gamma (Ifng), and chemokine (C-C motif) ligand 1 (Ccl1) was observed in T-cells isolated from perfused livers. Pleiotropic cytokines interleukin (IL)-6 and IL-27 were upregulated in perfused macrophages, and anti-inflammatory mediators including NLR family pyrin domain containing 12 (Nlrp12) were substantially downregulated.

Conclusions: NEVLP induced a global inflammatory signature, increasing expression of pro-inflammatory or pleiotropic cytokines and chemokines and decreasing expression of anti-inflammatory mediators. These changes were observed in multiple cell types, including T-cells, several macrophage subpopulations, and dendritic cells. The results from this study are critical for the optimization of targeted therapeutic interventions during machine perfusion.

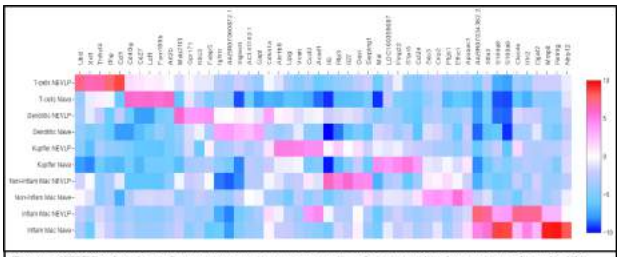

Figure 1. NEVLP induced an inflammatory gene expression signature. Gene expression signatures were determined for naïve and perfused livers using single cell RNA sequencing. A comparison of naïve and NEVLP livers showed that for T-cells, dendritic cells, and macrophages, there was an increase in expression of pro-inflammatory cytokines and chemokines and a decrease in expression of anti-inflammatory immune mediators.

Abstract# 530

Patterns and Inhibition of Cell Death During Static Cold Storage of Human Kidneys

J. R. DiRito[1], G. Chickering[2], J. T. Langford[1], D. Stern[1], S. Hosgood[3], M. L. Nicholson[3], E. Gavathiotis[4], R. N. Kitsis[5], M. Saltzman[2], J. S. Pober[6], G. T. Tietjen[7], *[1]Surgery, Yale School of Medicine, New Haven, CT, [2]Biomedical Engineering, Yale University, New Haven, CT, [3]Surgery, University of Cambridge, Cambridge, United Kingdom, [4]Biochemistry and Medicine, Wilf Family Cardiovascular Research Institute, Albert Einstein College of Medicine, Bronx, NY, [5]Surgery, Albert Einstein College of Medicine, Bronx, NY, [6]Immunobiology, Yale University, New Haven, CT, [7]Surgery and Biomedical Engineering, Yale School of Medicine, New Haven, CT*

Purpose: As the donor population continues to age and accumulate co-morbidities, more marginal kidneys are being retrieved for transplantation. However, estimates suggest that more than 40% of kidneys from extended criteria donors are discarded annually. Many of these kidneys are not considered for transplantation because we do not currently understand why these organs fail nor do we have appropriate strategies to preserve them. By studying human organs that were deemed unsuitable for transplantation, we can begin to define new modes of failure in particularly marginal organs.

Methods: To better appreciate how kidneys respond to cold ischemia, we biopsied a series of nine kidneys at times from 12 to 72 hours of cold storage.

Results: We found that older donors (70-74 y/o) had significantly more cell death visualized via TUNEL staining (Figure 1B) than younger donors (39-52 y/o) in this series (Figure 1A). Pervasive cell death throughout a biopsy became apparent in older donors between 30-36 hours of cold storage (Figure 1B). Preliminary data suggest that tubular epithelial cells are the predominate cell type positive for TUNEL staining as cold time increases. Additionally, Bax inhibitor BAI1 can significantly decrease cell death in models of human organ culture (Figure 2A), inhibiting cell death both during cold storage and after a period of warm injury.

Conclusions: These data suggest that cell death throughout the course of cold storage can be reduced by pharmacological intervention in marginal organs and thus may improve clinical outcomes.

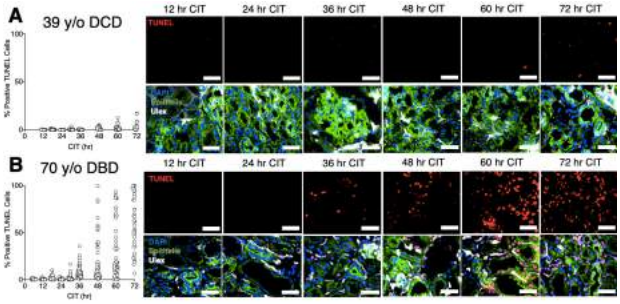

Figure 1. Cell death increases throughout the course of cold storage in kidneys from old donors. Quantification of cell death visualized with TUNEL staining in representative kidneys from younger (A) and older (B) donors throughout 72 hours of cold storage. (Red – TUNEL; Blue – DAPI; Green – Epithelial; White – Ulex) Scale bars are 50 μm.

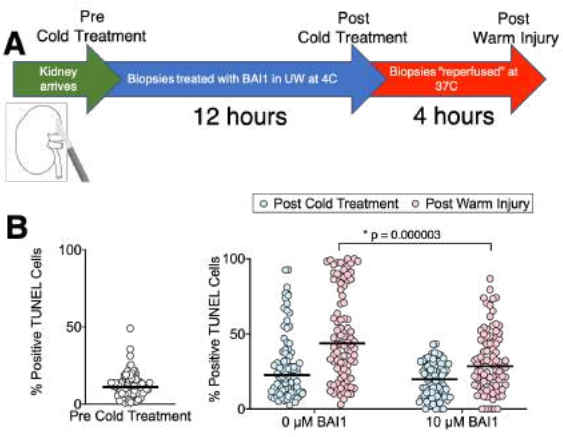

Figure 2. BAI1 can inhibit cell death during cold storage and after a period of warm injury. (A) Schematic of human organ culture model. (B) Quantification of TUNEL positive cells pre cold treatment, post cold treatment, and post warm injury. Each dot represents one 40X image. *p = 0.000003 using two-tailed student's t-test.

Abstract# 531

Ectopic Hepatocyte Transplantation Into the Lymph Nodes in a Fully Mismatched Allogeneic Dog Model Using Tacrolimus and Prednisone

P. A. Fontes, *NA, LyGenesis, Pittsburgh, PA*

Purpose: Develop organogenesis through ectopic hepatocyte transplantation (HT) into the upper abdominal lymph nodes (LN).

Methods: Three groups of Mongrel dogs weighting between 25-35 kg (control (C) n=3, autologous (AU) n=6; allogeneic (AL) n=21) underwent heterotopic HT into their LNs through either direct or endoscopic ultrasound (EUS) guided endoluminal injections. The hepatocytes were isolated from the liver left lateral segment of a donor group of animals (n=10) using a modified two-step collagenase perfusion method and transplanted using 3 different doses (low=75M, medium=150M and high=750M) through 1 ml infusions into the LNs. All the recipients underwent an end-to-side portacaval shunt (PCS) as a way to induce sub-acute liver failure and upregulation of hepatotropic factors. These recipients received immune suppressive (IS) therapy (Tacrolimus (Tac) and Prednisone) post-operatively for the duration of the experiments (30-180 days follow up).

Results: The median cold ischemia time for HT was 25.1 hours, ranging from 5.5 to 54.8 hours. The median cell viability was 81%. The C group had a 66% mortality. The AU and AL groups had survival rates of 75% and 78%, respectively. Early deaths were attributed to acute hepatic failure and ischemic bowel. Both primary end points for safety and efficacy were successfully achieved. The AU group had 100% engraftment and the AL 50%. The effect sizes for transplantation of hepatocytes were large for both the AU group (d=1.12, n=6, with one early death due to infection) and the AL group (d=1.01, n=21). A strong association between effect size and dose was also noted, with the highest dose (750M) having the largest effect size (d=2.65, n=3). Histopathological analysis showed the formation of normal ectopic hepatic tissue within the transplanted LNs, including the presence of sinusoids, portal triads and bile ducts in both AU and AL groups. Most animals were required to be maintained on sub-therapeutic Tac levels due to significant adverse events (neurotoxicity 30%, infections 18% and diabetes 12.5%.

Conclusions: Hepatocyte transplantation can be performed safely and effectively using this new minimally invasive EUS method under standard IS therapy in a fully mismatched allogeneic combination. Suboptimal IS yielded decreased engraftment in the AL group. The ectopic liver tissue had normal hepatic cytoarchitecture and no signs of acute cellular rejection up to 180 days follow up.

Abstract# 533

The Hepatoprotective Role of Innate Lymphoid Cells in Liver Transplantation

H. Kojima, H. Hirao, H. Zhang, K. Kadono, K. J. Dery, Y. Zhai, J. Kupiec-Weglinski, *The Dumont-UCLA Transplantation Center, Los Angeles, CA*

Purpose: Although NKp46$^+$group 3innate lymphoid cells (ILCs) (RORγt$^+$IL-22-producing NKp46$^+$cells) were reported to protect liver against ischemia-reperfusion injury (IRI), no study has demonstrated the contribution of ILCs in liver transplantation. Therefore, we investigate whether and how ILCs affect liver transplant outcomes in a mouse orthotopic liver transplantation (OLT) model.

Methods: Wild type (WT) C57BL/6J mouse liver grafts were subjected to the extended cold storage (4°C/18 hours) in UW solution to mimic the marginal donor livers in human OLT.To evaluate the role of ILCs in OLT, we transplanted the cold-stored grafts into: WTmice, Rag2 knockout (KO) mice that lack T and B cells, and Rag2-common-γ-chain double KO (Rag2-γc-DKO) mice that lack ILCs in addition to T and B cells (all in C57BL/6J background). We used 0.5 mg of anti-CD90.2 antibody (Bio X Cell) intravenously at 48 hours prior to transplantation to deplete ILCs in Rag2 KO mice. Liver IRI was evaluated at 6 hours post-Tx.

Results: Compared with WT and Rag2 KO, but not Rag2-γc-DKO, recipients were protected from liver IRI, as documented by serum ALT and AST levels, Suzuki's histological grading, quantities of infiltrating CD11b+ macrophages/Ly6G+ neutrophils, and frequency of TUNEL+ cells. Furthermore, depletion of ILCs with CD90.2 increased hepatocellular injury in Rag2 KO mice and diminished Rag2 KO and Rag2-γc-DKOmouse disparities, suggesting that recipient derived ILCs might exert protective function against IRI in OLT. The intra-graft gene expression of T-box transcriptional factor T-bet significantly increased while IL-23 decreased in Rag2 KO recipients as compared with Rag2-γc-DKOcounterparts.

Conclusions: This study is the first to reveal that ILCs might protect OLT from IRI, which provides us a novel therapeutic target for future clinical application in transplant recipients.

Abstract# 534

Pathways and Factors That Confer Therapeutic Properties of Adipose Derived Regenerative Cells in Reducing Ischaemia Reperfusion Injury in Kidney Transplantation

R. Lathan, P. Mark, M. Clancy, R. Touyz, *Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, United Kingdom*

Purpose: Studies in our rat model of ischemic reperfusion injury (IRI) demonstrate improved kidney function post injection of non-cultured autologous adipose-derived regenerative cells (ADRC). The mechanism on how these cells induce reparative effects during IRI remains elusive. We investigated ADRC-derived effects on the injured kidney utilizing single cell RNA-sequencing and pathway driven data-mining.

Methods: ADRC were harvested from inguinal F344 rats (pooled n=5). Stimulated ADRC were exposed for one hour to an ischemic and perfused kidney ex vivo in a transwell system as a mimic of the ADRC treated kidney transplant process and compared to non-stimulated ADRC with no kidney exposure. RNA from single cells was isolated from non-stimulated and stimulated ADRC using the 10X Chromium system and sequencing was performed on a Nextgen 500 at a target 30,000 reads/cell depth (Glasgow Polyomics). Two experimental runs were performed. Post R Seurat sequence analysis, non a priori and directed pathway analysis targeting previous experimental data which implicated anti-inflammatory pathways were evaluated using Ingenuity Pathway Analysis. Sequenced ADRC data results were compared to transcript expression uncovered in the whole rat animal model IRI kidney through qPCR (n=6-8).

Results: Three merged runs of both Stimulated and Non-stimulated ADRC yielded an average of 6018 cell transcriptomes and 18 distinct cell cluster populations - an enrichment in leukocytes, but also included mesenchymal stem cell and adipocyte populations. Stimulated ADRC yielded 786 cell transcriptomes - primarily T-cell and antigen presenting cell clusters. Cell death transcript expression and low cell yield of treated ADRC suggest higher apoptotic ADRC activity after exposure to the injured kidney. Cell pathways differentially expressed between the two groups implicated a helper T-cell, Th1 profile, an IL-17, and a regulatory pathway, indicating a highly active and proliferating T-cell response. Transcript analysis in IRI and ADRC-treated kidneys showed an increase in cytotoxic T-lymphocyte-associated protein 4 starting at day 48 post treatment. At 48 hours post-treatment, IRI kidneys also contained higher levels of CD45+ leukocytes as assessed by histology and flow cytometry compared to vehicle controls, implicating an immune and regulatory effect of ADRC treatment.

Conclusions: Pathway analysis in ADRC alone implicate a role for immune cells in modulating the immune response in the IRI kidney. Collectively, gene expression and histological evidence in the model and in ADRC ex vivo suggest that ADRC treated IRI kidneys experience early anti-inflammatory changes involving T-cell and antigen presenting cell subsets that ultimately generate an anti-inflammatory environment in the IRI treated kidney.

Abstract# 535

Lacripep™-like Peptide N-104 Promotes Beta Cell Proliferation in Murine Pancreatic Islets

M. Ma, P. Chhabra, K. Fread, K. Dias Teixeira, G. Laurie, K. Brayman, *University of Virginia Health System, Charlottesville, VA*

Purpose: To monitor time-dependent cellular changes, with emphasis on beta cell regeneration, in pancreatic islets following treatment with Lacripep™-like peptide N-104 by mass cytometry. **Background:** Lacritin is a multifunctional tear protein with prosecretory, prosurvival and mitogenic properties. Islets are Lacritin responsive, and prominently express known elements of the Lacripep™ receptor complex and signaling pathways. N-104 peptide comprises the fifteen C-terminal amino acids of Lacritin. Mass cytometry was used to measure the expression of proliferative markers of all major endocrine cells as well exocrine cells.

Methods: Mouse islets were cultured with 4 μM N-104, or negative control peptide C95, or left untreated for 24 hours, following which islets were dissociated into single cells by treatment with trypsin. Single cells were fixed and stained with 35 antibody markers. Mass cytometry data were obtained on CyTOF2 (Fluidigm) at the Flow Cytometry core at UVA.

Results: At the single cell level, N-104 stimulated the proliferation of all major endocrine cells. Ki67 was measured as a marker for proliferation. Proliferation of alpha cells, identified by the expression of marker Proprotein convertase 2 was 0.90% for N-104 treated islets, 0.32% for untreated islets and 0.24% for negative control C-95. Proliferation of alpha cells using Glucagon as marker was 1.12%, 0.64% and 0.69% for N-104 treated, untreated and C-95 treated islets respectively. Proliferation of beta cells as identified by cytoplasmic insulin and proinsulin was the most significant - in keeping with the enhancement of glucose-stimulated insulin secretion that was observed in parallel. Proliferation of beta cells, identified by NKX6.1 was 2.88% for N-104 treated islets, 1.28% for untreated samples and 1.62% for C95 treated islets. Proinsulin showed increases of 3.87%, 1.00% and 1.44% and Insulin showed increases of 5.02%, 1.14% and 1.92% for N-104 treated, untreated and C-95 treated samples respectively. To a lesser degree, N-104 also enhanced delta and ductal cells proliferation - without substantially affecting acinar cells identified by markers PDX1, SST, and CD44.

Conclusions: Our data indicate that systemic N-104 treatment promoted single cell proliferation in islets, especially that of beta cells, without affecting exocrine acinar cell proliferation.

Abstract# 537

Platelets Stimulate Liver Regeneration After Partial Liver Transplantation

K. Takahashi, C. Liang, K. Furuya, T. Oda, *GI and HBP Surgery, University of Tsukuba, Tsukuba, Japan*

Purpose: Living donor liver transplant (LDLT) can sometimes be associated with impaired regeneration and severe ischemia/reperfusion (I/R) injury in the liver graft, resulting in small-for-size syndrome. Platelets are considered to act in concert with activated Kupffer cells (KCs) and leukocytes, which can be the core mechanisms for I/R injury. Recent studies highlighted platelets have strong effects on promoting liver regeneration. However, these studies are based on partial hepatectomized model, and the results in LDLT haven't been thoroughly investigated. The aim of our study was to identify the role of platelets in liver graft regeneration and its outcomes after partial LT.

Methods: We used a rat model of partial LT to mimic human LDLT. Firstly a 30% partial LT was performed. Recipient rats were treated with thrombopoietin before operation (TPO group), or given phosphate-buffered saline administration as control (control group). Postoperative parameters for regeneration and I/R injury were evaluated after transplantation. Both donors and recipients were administrated with clodronate liposome to deplete KCs (KDTPO group), changes in liver regeneration were analyzed. Secondly, a 20% partial LT was performed, and the effect of thrombocytosis on postoperative survival was evaluated.

Results: The liver-to-body weight ratio was significantly higher post-LT in the TPO group compared with the control group. In western blot, the phosphorylation of Stat3, Nf-κB and CyclinD1 are increased in the TPO group. For I/R injury-related parameters, thrombocytosis didn't aggravate the oxidative stresses and their downstream pathways (Fig1). After KC depletion, platelet accumulation was significantly lower in the KDTPO group compared with the TPO groups, and platelet-induced increment of IL-6 and TNF-α were cancelled . Thrombocytosis improved postoperative survival in the TPO group (Fig 2).

Conclusions: Our results suggested that thrombocytosis stimulated graft regeneration without aggregating I/R injury after partial LT, and Kupffer cells vitally contributed to platelet-derived regeneration. Platelet therapies to increase perioperative platelet counts may improve the outcomes after LDLT.

Abstract# 538

The Tumor-suppressor Signaling of the α1-na/k-atpase- Cav-1-src Complex at the Caveola in Nash Related Hepatocellular Carcinoma

U. S. Udoh[1], J. D. Sanabria[1], M. Banerjee[1], P. K. Rajan[1], M. Schade[1], J. A. Sanabria[1], A. Mallick[1], G. Smith[1], G. U. Udoh[2], K. Sodhi[1], S. Pierre[2], Z. Xie[2], J. Shapiro[2], J. Sanabria[1], *[1]Dept. of Surgery/ Marshall Institute for Interdisciplinary Research, Marshall University, Huntington,, WV, [2]Marshall Institute for Interdisciplinary Research, Marshall University, Huntington,, WV*

Purpose: Hepatocellular Carcinoma (HCC) is the 2nd and fastest-growing cause of cancer related mortality worldwide, mainly from the metabolic cellular disturbances promoted by the epidemic of obesity and a lack of markers for its early detection. Our group has identified a novel signaling pathway, comprising of the α1-Na/K-ATPase (NKA), Caveolin-1 (Cav-1) and Src kinase (Src) which is necessary for cell development and function. In carcinogenesis, regulation of Src-phosphorylation by the α1-subunit of the Na/K-ATPase at caveola may initiate protein interactions, beginning at Cav-1 in the plasma membrane that leads to a disequilibrium in the SMAC-Survivin apoptotic signaling in the cell, resulting in a pathogenic "apoptotic switch" that favors HCC tumorigenesis. We propose that these interactions are relayed via the PI3K- Akt- S6K1 and the EGFR- STAT 3 signaling pathways from cell membrane to its interior. We hypothesize inhibition of α1-Na/K-ATPase-CAV-1-Src signaling as putative target for the treatment of HCC.

Methods: Expression of Cav-1/SMAC-Diablo/Survivin proteins was performed by confocal-microscopy on immuno-stained livers from HCC, NASH and nor-

mal human subjects, and rodent models. NASH and HCC mice were exposed to doses of pNaKtide, an inhibitor of Scr-phosphorylation at the NKA α1-caveolin-1 complex. Significant differences among groups were established at p<0.05 using ANOVA/t-test.

Results: The expression of Cav-1 was significantly higher in liver tissue from patients with NASH±HCC vs normal livers or livers with metastases (p<0.05). Survivin expression was significantly higher in patients with NASH/HCC+ vs NASH/HCC-, normal livers, and liver with metastases (p<0.05). In contrast, SMAC protein expression was significantly lower in liver tissue with NASH or HCC vs controls. Similar results were obtained in the murine models. In mouse models, pNaKtide, significantly restored SMAC expression and attenuated Survivin expression in a dose-dependent manner (p<0.01). Also, in HCC murine model, pNaKtide treated groups showed a significantly dose- dependent lower tumor burden as well as fibrosis vs the untreated group(p<0.01). On the contrary, apoptosis increased significantly in pNaKtide treated groups vs untreated group (p<0.05).

Conclusions: Cav-1, SMAC and Survivin proteins expression differed significantly in patients with HCC and NASH when compared to normal livers or livers with metastases. This observation was validated in NASH and HCC murine models. Inhibition α1-Na/K-ATPase-CAV-1-Src signaling pathway by pNaktide resulted in the reversal of the "oncogenic apoptotic switch", leading to HCC prevention/ tumor regression.

Abstract# 539

Human Liver-derived Mesenchymal Stromal Cells (MSC) are Superior Inhibitors of Natural Killer Cells Compared to Bone Marrow or Adipose Tissue-derived MSC

F. Yigitbilek, M. J. Hansen, W. D. Park, M. D. Stegall, T. Taner, *Mayo Clinic, Rochester, MN*

Purpose: Guided by the liver allografts' unique tolerogenic microenvironment and the immunoprotective impact on simultaneously transplanted organs, we recently isolated liver mesenchymal stromal cells (L-MSC) and demonstrated that they inhibit alloreactive T cell responses better than their counterparts from bone marrow (BM-MSC) or adipose tissue (A-MSC). Here, we compared the impact of L-MSC on natural killer (NK) cell functions to those of BM-MSC and A-MSC.

Methods: L-MSC were obtained from deceased donor allografts, while BM-MSC and A-MSC were derived from living kidney donors at the time of procurement (n=6 each). Comparative proteomic analysis was done on the secretome of each cell type. Primary NK cells were isolated from blood donor waste products using an NK cell isolation kit, stimulated with IL-2 (100U/mL), and cultured with MSC in a ratio of 10:1. Surface marker expression was assessed by Flow Cytometry, IFNɣ production by ELISA, and NK function by target cell cytolysis after 3 days of co-culture.

Results: The PCA analysis showed that the L-MSC secretome clustered together, and was distinctly different than the A-MSC and BM-MSC secretomes. Specifically, multiple proteins involved in NK activation were reduced >2-fold (p<0.05), and those involved in NK inhibition were in upregulated >2-fold (p<0.05) in L-MSC cultures. Compared to NK cultured with BM-MSC or A-MSC, NK cultured with L-MSC had reduced surface expression of the two activation markers, Nkp44 (14.2% vs. 20.8% and 27.2%) and NkG2D (10.2% vs. 24.2% and 33.4%) (p<0.05, both) (Figure 1). Similarly, L-MSC reduced IFNγ production by NK cells by 54% (p<0.05), compared to 50% by BM-MSC and 37% by A-MSC (p<0.05). Although all three MSC reduced the cytolytic function of NK cells, the biggest reduction was observed in NK cells co-cultured with L-MSC (34% vs. 40% and 38%; p<0.05).

Conclusions: These results suggest that L-MSC are superior to BM-MSC and A-MSC in inhibiting NK cell activation and cytolytic function in vitro. These findings provide further evidence for the immunomodulatory properties of L-MSC in their potential utilization as cellular therapeutics in the pathogenesis of autoimmune diseases and transplantation.

Abstract# 540

Src Kinase Inhibitor Pp1 Blunts Tgf-β1 Dependent Endothelial-to-Mesenchymal Transition to Alleviate Allograft Kidney Fibrosis Through Orchestrating β-catenin Signaling

Z. Gui, Z. Wang, Z. Han, J. Tao, X. Ju, R. Tan, M. Gu, *Urology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Purpose: Allograft fibrosis is an important contributor to graft loss in chronic renal allograft injury. Endothelial-to-mesenchymal transition (EndMT), dysfunction of endothelial cells, played a vital role in formation of transplanted kidney fibrosis. Src family kinases (SFKs), an important group of proto-oncogenes, were reported to play a critical role in formation of renal fibrosis. However, the effect of Src in formation of allograft kidney fibrosis remains to be determined.

Methods: Expression of Src Kinase in CAD were examined compared with non-rejecting tissue. The long-term prognosis of CAD patients were analyzed with the Src Kinase expression. HUVECs were primarily extracted and cultured. Transforming growth factor-β1 (TGF-β1) was used to induce EndMT. Src Kinase activation was tested in cell culture. Upon silencing Src or using Src Kinase Inhibitor PP1, progression of TGF-β1 induced EndMT related cellular remodeling, extra cellular matrix (ECM) production, cell migration and invasion, were tested. By establishing rat kidney transplantation model, the protective role of PP1 in allograft fibrosis and survival rate of allo-recipients were investigated.

Results: In this study, we found significantly higher expression of Src Kinase in CAD compared with non-rejecting tissue, and downregulation of Src Kinase was negatively related to poor prognosis in CAD patients. In addition, we observed the Src Kinase activation in transforming growth factor-β1 (TGF-β1) induced EndMT. Upon silencing Src or using Src Kinase Inhibitor PP1, progression of TGF-β1 induced EndMT related cellular remodeling, extra cellular matrix (ECM) production, cell migration and invasion, got significantly reverted. Then, we found Src kinase controlled the progression of EndMT by orchestrating β-catenin signaling. By establishing rat kidney transplantation model, we confirmed the protective role of PP1 in allograft fibrosis and survival rate of allo-recipients. Then, our outcomings revealed PP1 alleviated TGF-β depended EndMT in allograft organ. In *vitro* study, we furtherly confirmed our *vivo* findings.

Conclusions: In conclusion, to the best of our knowledge, the present study was the first to investigate the role of Src kinase in allograft kidney and suggest that PP1 blunts TGF-β1 dependent EndMT to alleviate allograft kidney fibrosis through orchestrating β-catenin signaling.

Abstract# 541

Extracellular Vesicles from Patients with Diabetic Nephropathy Induce Endothelial Dysfunction Through Icam-1 and Vcam-1 in an In Vitro Model

E. Montagud-Marrahi[1], S. Torramadé-Moix[2], M. Ramirez-Bajo[3], J. Rovira[3], E. Bañón-Maneus[3], E. Hermida[1], F. Diekmann[1], M. Palomo[4], M. Díaz-Ricart[2], P. Ventura-Aguiar[1], *[1]Nephrology and Kidney Transplantation Department, Hospital Clínic de Barcelona, Barcelona, Spain, [2]Hematopathology Department, Hospital Clínic de Barcelona, Barcelona, Spain, [3]Nephrology and Transplant Experimental Laboratory (LENIT), Hospital Clínic de Barcelona, Barcelona, Spain, [4]Josep Carreras Leukaemia Research Institute, Hospital Clínic de Barcelona, Barcelona, Spain*

Purpose: Extracellular Vesicles (EVs) are membranous structures produced by cells which contain different cytoplasmic compounds and that have been described as potentially pathogenic elements in endothelial dysfunction (ED) through a modification of the expression of endothelial receptors. The mechanisms of ED in patients with chronic kidney disease (CKD) and diabetes mellitus (DM) are not well defined, although EVs could have a key role. Thus, the aim of the study was to evaluate the role of EVs in ED in patients with diabetes and ESKD in an *in vitro* model of ED.

Methods: Cross-sectional study with sera from 11 patients with a mean age of 46±7.6 years (45% women) and CKD (eGFR 18±7 mL/min) due to diabetic nephropathy (DM1), grouped into 4 pools. The role of the EVs was studied in an *in vitro* model of ED with HMEC-1 cells exposed during 72 hours to supplemented medium with: a) patient sera (group 1/red), b) EVs-depleted patient sera (group 2/orange) and c) EVs-depleted control sera in which patient's EVs were added (group 3/yellow). Changes in the expression of vWF and the membrane adhesion receptors VCAM-1 and ICAM-1 were analyzed in the cells exposed to the different conditions, with respect to the healthy donor serum.

Results: The expression of ED markers (vWF, VCAM-1 and ICAM-1) in cells exposed to patient serum (with or without EVs) was higher compared to that observed after exposure to control sera (vWF, p <0.01; Fig. 1A; VCAM-1, p <0.01; Fig. 1B; ICAM-1, p <0.01; Fig. 1C). Moreover, EVs depletion significantly decreases the expression of VCAM-1 and ICAM- 1 with respect to the patient's serum (Fig. 1B, p <0.01 and 1C, p <0.01), but not vWF expression.

Conclusions: EVs increase endothelial damage through an increased VCAM-1 and ICAM-1 expression, both being inflammatory markers associated with leukocyte adhesion. Thus, EVs constitute a pathogenic element in ED in patients with DM1 and CKD.

Abstract# 542

HLA I Antibody-Activated Endothelium Polarized M2-Like Macrophages with Increased Efferocytic and Phagocytic Capacity

J. Nevarez-Mejia[1], X. Wei[1], N. M. Valenzuela[1], M. Rossetti[1], H. Pickering[1], G. A. Fishbein[1], A. Mulder[2], E. F. Reed[1], *[1]Pathology and Laboratory Medicine, UCLA, Los Angeles, CA, [2]Immunohematology and Blood Transfusion, LUMC, Leiden, Netherlands*

Purpose: The role of intragraft macrophages (Mϕs) during antibody-mediated rejection (AMR) remains unclear. Anti-HLA Abs during AMR drives vascular inflammation as seen by monocyte recruitment and endothelial cell (EC) injury. Prior studies in our lab have indicated that monocyte and HLA I Ab-activated EC interactions skew monocytes to resolving M2-like phenotypes (CD68+CD206+CD163+). In this study, we validated the capacity of HLA I Ab-activated EC polarized Mϕs to a) efferocytose apoptotic ECs and b) phagocytose *E.coli* particles as in the setting of graft injury or infection, respectively. Moreover, we identified immune responses post-engulfment.

Methods: Using a transwell *in vitro* co-culture system, human primary aortic ECs were stimulated with allele specific HLA I hIgG or HLA I $F(ab')_2$ Ab portion, anti-CD105 Ab, TNF-a, hIgG isotype control, or left untreated. Third-party human monocytes added above activated ECs transmigrate to the bottom chamber and differentiate into Mϕs (5-days). Cytokine-polarized Mϕs (M1/M2) were generated as controls. EC apoptosis was induced using TNF-a and cycloheximide (16-hours) and was validated via caspase-3 activation. Apoptotic ECs and *E. coli* particles were labeled with pHRodo (pH sensitive dye; measured by FITC). Mϕs were co-cultured with labeled apoptotic ECs or *E.coli* particles for 24-hours. The phenotype of $FITC^{Pos}$ Mϕs was measured by flow cytometry. Cytokine secretion of culture supernatants from Mϕs treated with target cells and untreated Mϕs was measured via Luminex.

Results: All transwell polarized Mϕs exhibited significantly higher levels of apoptotic EC efferocytosis (~20-40% $FITC^{Pos}$) and *E.coli* phagocytosis (~60-80% $FITC^{Pos}$) compared to cytokine-polarized Mϕs. Immune profiling results show that $FITC^{Pos}$ Mϕs post-apoptotic EC efferocytosis increased expression of CD40, CR1, and CD71 compared to $FITC^{Neg}$ Mϕs. Precisely, TNF-a activated EC polarized Mϕs significantly increased CD163 (*p=0.03) compared to untreated EC polarized Mϕs. Moreover, all transwell conditions exhibited an added increased in adhesive molecules (ICAM-1, CCR2, and PSGL-1) post-*E.coli* phagocytosis. Specifically, HLA I IgG Ab-activated EC polarized Mϕs significantly increased CR1 (*p=0.03) compared to untreated EC polarized Mϕs. Mϕ culture supernatants following apoptotic EC efferocytosis significantly increased FGF-2 while culture supernatants post-*E.coli* phagocytosis increased inflammatory cytokines (e.g. IL-6, IL-8, and IL-1b).

Conclusions: Our studies indicate that endothelium polarized M2-like Mϕs exhibit high efferocytic and phagocytic capacities, and activate immune responses which are enhanced by TNF-a and HLA I Abs. This provides insight into Mϕ functions which may help mediate vascular repair, and clearance of pathogens following transplantation.

Abstract# 543

IFNγ, and to a Lesser Extent TNFα, Elicits Protracted Endothelial Cell Expression of Costimulatory Molecules and Antigen Presentation Machinery

N. M. Valenzuela, *Pathology and Laboratory Medicine, UCLA, Los Angeles, CA*

Purpose: Beyond simply "recruiting" leukocytes to sites of injury, local stimulation by the donor vascular compartment may prolong alloimmune responses. Moreover, the dynamics of endothelial resolution of inflammation, particularly with respect to costimulatory phenotype, is not well-defined. We characterized the repertoire of cytokines, antigen presentation and costimulatory/coinhibitory molecules produced by inflamed vascular endothelial cells (EC), under chronic stimulation and after short cytokine priming and prolonged withdrawal.

Methods: Human aortic EC were stimulated with continuous TNFα or IFNγ for 1-48hr, or primed with TNFα or IFNγ for 3hr, before withdrawal of stimulus for up to 45hr. mRNA were measured by Nanostring; protein were measured by flow cytometry, ELISA and Luminex. Key findings were confirmed in primary human EC from 4-6 different vascular beds, and publicly available datasets were leveraged to further corroborate the findings.

Results: 42 genes encoding antigen presentation, costimulation/coinhibition molecules or cytokines were upregulated in EC by TNFα, IFNγ or both. 35 other cytokines, antigen presentation and costimulatory genes were either not found to be expressed by endothelium or were expressed but not induced by TNFα or IFNγ. TNFα triggered IL6, IL6ST, IL15, TRAIL and BAFF production from EC as an intermediate phase (>6hr) response, while IFNγ stimulated only TRAIL, BAFF and IL15 after 18hr. EC upregulated CD40, ICOSL, HVEM, PD-L1, PD-L2 and 4-1BB as early as 3hr, and down-regulated B7-H3, in response to TNFα; while IFNγ increased CD40, HVEM, PD-L1 and PD-L2. TNFα augmented expression of HLA I, TAP1 and immunoproteasome components; while IFNγ also increased HLA II, CIITA, and CD74. After only short (3hr) cytokine priming and extended withdrawal from cytokine exposure, TNFα-induced HLA I, IL6ST and PD-L2 were enhanced at 24hr, but other TNFα-induced molecules rapidly contracted. In contrast, HLA I, HLA II and proteasome induction at 48hr was elevated whether IFNγ was chronic or withdrawn. In addition, nearly all IFNγ-induced costimulatory molecules and cytokines persisted up to 45hr after IFNγ withdrawal.

Conclusions: Although endothelial cells lacked CD28 ligands (CD80, CD86) and did not produce many of the typical cytokines needed for Th skewing, they could

be provoked to express PD-1 ligands, CD40 and other cytokines that can bias T cell activation. We were also surprised to find that activated EC elaborated BAFF and IL-15, cytokines which shape B cell and NK cell survival and activation. In addition to different profiles elicited by TNFα to IFNγ, our results show that IFNγ elicits prolonged gene expression changes and immune phenotype alterations that persist days after initiation. That systemic and tissue resident vascular EC possess a wide constellation of costimulatory molecules suggest that adaptive immunity takes shape not only in secondary lymphoid organs but also locally in the periphery.

Biomarker Discovery and Immune Modulation

Abstract# 544

Hypoxia Inducible Factor 1á (HIF-1á) Regulates Carcinoembryonic Antigen-related Cell Adhesion Molecule-1 (CEACAM1) Splice Isoforms to Protect Against Ischemic Injury in Mouse and Human Liver Transplantation

K. J. Dery, H. Kojima, K. Kadono, H. Hirao, J. W. Kupiec-Weglinski, *The Dumont-UCLA Transplantation Center, Los Angeles, CA*

Purpose: CEACAM1 (CC1) is a transmembrane glycoprotein that undergoes extensive alternative splicing (AS) to generate CC1-S and CC1-L. It is currently unclear which of these two cytoplasmic isoforms is involved at the interface of immune liver injury and metabolic homeostasis.
Methods: Murine studies used warm liver IRI (wIRI) for 6 h or 7 days to assess RNA splicing in CC1. Primary hepatocytes were cultured under hypoxia-reoxygenation (H/R) stress conditions to mimic liver wIRI. Antisense oligomer morpholinos, targeting CC1 exon 7, were used to induce "cytoprotective" hepatocyte CC1-S signaling under hypoxic conditions in hepatocyte cultures and orthotopic liver transplant (OLT) settings. Human liver biopsies were obtained 2 h after reperfusion and analyzed by qRT-PCR-assisted detection of CC1-S and HIF-1α.
Results: Longitudinal CC1 AS mRNA isoform profiles were analyzed in a wIRI model. The peak of CC1-S occurred at 6 h (P<0.0009) and 7d (P<0.0007), reflecting combinatorial interactions at the CC1 variable exon 7. We addressed next how CC1 is regulated by oxidative stress by investigating the role of HIF-1α. Notably, in the presence of HIF-1α, under cold stimuli, CC1 responded to hepatocyte damage by dramatically upregulating its expression (P<0.001). This correlated with a decrease of p38 MAPK levels (P<0.001), a negative regulator of hepatic autophagy pathways. As proof-of-principle, wild-type mice treated with antisense morpholinos targeting CC1 exon 7 and subjected to warm IR-stress showed marked improvement of liver function, increased CC1-S in the liver, and spleen (P<0.0001). To clinically validate the murine findings, we retrospectively analyzed hepatic biopsies from fifty-five human OLT patients. We found a positive correlation between CC1 and HIF-1α levels in post-transplant donor liver biopsies (P<0.0128). Human OLTs divided into "low" (n=20) vs. "high" (n=20) CC1-S expression groups (n=40) showed high CC1-S levels were accompanied by improved pre-OLT hepatocellular function.
Conclusions: This novel translational study identifies oxidative stress and hepatic tissue injury as catalytic drivers of CEACAM1 AS. The uncovered HIF-1α - CC1-S cytoprotective axis points toward its function in alleviating hepatic IRI and improving OLT survival/outcomes.

Abstract# 545

Microbial Signatures Promote Antibiotic-Mediated Alleviation of Peritransplant Liver Damage in Mouse Recipients

K. J. Dery[1], S. Kageyama[1], H. Hirao[1], H. Kojima[1], K. Kadono[1], T. Dong[2], J. W. Kupiec-Weglinski[1], *[1]The Dumont-UCLA Transplantation Center, Los Angeles, CA, [2]Department of Medicine, Vatche & Tamar Manoukian Division of Digestive Diseases, UCLA, Los Angeles, CA*

Purpose: Although recent evidence shows that modifications of gut microbiota by antibiotics (Abx) influences liver allograft function, its compositional role in orthotopic liver transplantation (OLT) remains unknown. Here we aimed to determine how recipient Abx pretreatment affects hepatic ischemia-reperfusion injury (IRI) and OLT outcomes.
Methods: C57BL/6 recipient mice were pretreated with amoxicillin (Amx) or metronidazole (Mtz) prior to transplantation of Balb/c livers subjected to ex-vivo hepatic cold storage (18 h/4C). Groups of C57BL/6 mice were fed Amx or Mtz (days -11 to -1) and then conditioned with or without fecal microbiota transfer
(FMT) by gavage from naïve C57BL/6 mice (200 mg/ml; day -1 and 0) prior to OLT. Genomic DNA of fecal samples was then isolated and subjected to microbiome 16S rRNA gene sequencing.
Results: Taxonomic classification revealed significant differences between the Amx-treated and untreated groups in the family-, genus, and species-level analyses. Faith's Phylogenetic Diversity index, Shannon Index, and Chao1 Index all revealed significant declines in taxon richness, species diversity, and overall abundance after Amx-treatment alone (p<0.0001 in each index). By contrast, FMT re-established the microbiota to Sham and OLT-levels, suggesting that normal commensal flora is antagonistic to liver IRI-resistance. The bacterial phyla Verrucomicrobia and Firmicutes showed the largest decline of representation in the Amx-treated microbiota compared to Sham-treated mice. Remarkably, Mtz pretreated OLT recipients experienced severe IRI, with increased sALT (8853Â±353.5 vs. 5486Â±1345 U/L, p<0.05), augmented Suzukiâ€™s score, TUNEL+ cells, and graft-infiltrating neutrophils/macrophages, and decreased hepatic EP4 expression vs. controls. However, adjunctive FMT in Mtz-treated OLT recipients mitigated IR-stress and restored hepatocellular function to control levels (sALT: 4301Â±2145U/L, ns vs. control, p<0.05 vs. Mtz group).
Conclusions: This study documents the striking benefits of microbiota modulation in a clinically relevant mouse OLT model; and identifies a specific microbiota genus profile as a target for novel therapeutic manipulation in IRI-OLT.

Abstract# 546

Neutrophil CEACAM1 Induces Hepatic Autophagy and Shapes Innate-adaptive Immune Response in Liver Transplantation: From Mouse-to-human

H. Hirao[1], H. Kojima[1], K. Kadono[1], K. J. Dery[1], K. Nakamura[2], D. G. Farmer[1], F. M. Kaldas[1], J. W. Kupiec-Weglinski[1], *[1]Surgery, Dumont-UCLA Transplant Center, Los Angeles, CA, [2]Surgery, Kyoto University, Kyoto, Japan*

Purpose: Although CEACAM1 (CC1; carcinoembryonic antigen-related cell adhesion molecule 1; CD66a) regulates innate-adaptive immunity, its role in orthotopic liver transplantation (OLT) remains unknown. CC1 expresses two isoforms, i. e., CC1 short (CC1S) and CC1 long (CC1L) isoform. The CC1L isoform in mouse OLTs has been confined primarily to host-derived circulating infiltrating neutrophils. Here, we analyzed mouse and human OLT biopsies (Bx) to determine as to whether/how neutrophil CC1L isoform may contribute to OLT outcomes.
Methods: In the experimental arm, donor WT (C57/BL6) livers were transplanted, after cold storage (4oC/18h), to groups of syngeneic WT or CC1-deficient
(CC1-KO) mouse recipients, and sampled at 6h post-OLT. In parallel in vitro study, neutrophils isolated from WT or CC1-KO mice were cultures with: 1/ LPS or IL-4 adjunct; or 2/ co-cultured with WT bone marrow macrophages stimulated with LPS. In the clinical arm, human hepatic biopsies obtained at 2h post-OLT Bx
(n=55) were screened for CC1L, ATG5, ATG7, LC3B expression (Western blots) and for pro-inflammatory phenotype (RT-PCR).
Results: Mouse OLTs (WT) were negative for CC1L expression when transplanted to CC1-KO but not to WT recipients. Recipient CC1 null mutation augmented IRI-OLT (WT>CC1-KO) as evidenced by increased sAST/sALT levels (p<0.05), deteriorated pro-inflammatory cytokine/chemokine programs (p<0.05) and impaired post-LT autophagy induction. CC1-KO neutrophils showed higher amount of IL-1β/elastase expression and depressed arginase-1 after LPS challenge; and decreased p-stat6 levels in response to IL-4 stimulation. In neutrophil-macrophage co-culture system, CC1-proficient, but not CC1-KO neutrophils suppressed macrophage activation after LPS stimulation. Consistent with mouse data, CC1L expression in human liver Bx correlated positively with ATG7 (r=0.2628,
p=0.0526), ATG5 (r=0.2994, p=0.0264) and LC3B (r=0.2739, p=0.0430). When divided into low (n=28) vs. high (n=27) CC1L expression groups, CC1L low human OLTs showed enhanced innate/adaptive immune activation, and higher incidence of early allograft dysfunction (EAD; 28.6% vs 11.1%).
Conclusions: As a checkpoint regulator of IR-stress and sterile inflammation, neutrophil CC1L may serve as a novel biomarker and target for therapeutic modulation in OLT recipients.

Abstract# 547

Treg Lymphotoxin Engages Lymphotoxin Receptor on Cancer and Endothelial Cells to Promote Cancer Metastatic Migration: Mechanisms for Treg-Cancer Interactions

W. Piao, R. Oakes, C. Paluskievicz, J. Christopher, J. Bromberg, *U Maryland, Baltimore, MD*

Purpose: Treg immune suppression which is critical for transplant graft survival may also enhance tumor growth and metastases. Treg lymphotoxin (LTα1β2) may directly engage the LT beta-receptor (LTβR), which most tumor cells express, and signal through classical p65 and non-classical (NIK) NFκB pathways. We tested the hypothesis that direct Tregs-cancer cell interactions stimulate LTβR NFκB signaling pathways and influence the migration of cancer cells.

Methods: The murine melanoma cell line B16F10-eGFP and murine dermal lymphatic endothelial cells (LEC) were used in biochemical, phenotypic, and functional analyses of LTβR signaling and migration assays. Murine CD4 T cells or Tregs were isolated from wild type or $LT\alpha^{-/-}$ mice, and co-cultured with tumor cells or LEC. LTβR signaling was assessed with western blots and immunohistochemistry, and with highly specific LTβR-NFκB blocking peptides.

Results: LTβR was highly expressed on B16-F10 and many other cancer cells. LTβR classical NFκB signaling was constitutively activated in B16-F10, leading to higher expression of VCAM-1, CCR5, CXCL10 and CCL2 which were enhanced by inflammatory cytokines and suppressed by LTβR-NFκB-p65 blocking peptide. LTβR non-classical NFκB-NIK signaling was also constitutively activated, leading to expression of CCL21, CCL27, and CXCL12 which were suppressed by LTβR-NFκB-NIK blocking peptide. Cancer cells chemotactically migrated across LEC, and migration was prevented by inhibiting cancer cell NFκB-NIK signaling. Treg LTα1β2 further stimulated cancer cell LTβR to enhance cancer cell migration. $LT\alpha^{-/-}$ Treg failed to stimulate cancer cell migration, so that Treg regulated cancer cell migration is LT dependent. Treg LTα1β2 also stimulated LTβR on LEC, which conditioned the LEC by down regulating the cell junction molecule VE-cadherin, and thus further promoted cancer cell migration. Co-inoculation of B16-F10 with inhibitors of NFκB signaling suppressed melanoma tumor growth and metastases in vivo.

Conclusions: Treg LTα1β2 directly signals LTβR on cancer cells to promote cancer cell metastatic migration. Treg LTα1β2 directly signals LTβR on LEC to promote cancer cell transendothelial migration. LTβR-NFκB-signaling blocking peptides suppress cancer migration and chemokines to block cancer metastatic invasion. These observations provide a rational strategy to modulate Treg activities to prevent tumor spread in transplant recipients.

Abstract# 548

Development of a Lateral Flow Assay Detecting CXCL9 within Antibody Mediated and Acute T Cell Mediated Rejections After Kidney Transplantation

L. K. Seiler[1], R. Jonczyk[1], P. Lindner[1], L. Phung[1], C. Falk[2], C. Blume[1], *[1]Faculty of Natural Sciences, Institute of Technical Chemistry, Hannover, Germany, [2]Institute of Transplant Immunology, Medical School Hannover, Hannover, Germany*

Purpose: Despite tremendous improvements in quality and tolerability of immunosuppressive medications after successful kidney transplantation, numerous kidney grafts undergo acute and chronic rejections with following function loss. To detect and treat rejections as early as possible, follow-up examinations are mandatory and here the gold standard is represented by kidney graft biopsies. However, these sensitive examinations are not harmless and involve risks like bleeding and infections. Therefore, an easy-to-use lateral flow assay (LFA) for kidney transplant recipients (KTRs) was developed in the here presented project.

Methods: CXCL9 in urine and plasma samples from kidney graft recipients were analyzed by multiplex-ELISA. This messenger protein out of a group of homologous chemokines is an early signal produced within rejection episodes, e.g. by human macrophages presenting allogen or by the activated renal graft endothelium itself. Based on the identified range of relevant CXCL9 concentrations in urine and plasma samples, a LFA was developed. Initially, spiked buffer was used and the lateral flow assay was established. Following, samples from patients with kidney rejections as well as samples of unsuspicious patients as negative controls were applied onto the optimized LFA.

Results: An association between acute T cell mediated and antibody mediated chronic rejections and CXCL9 in plasma and urine could be determined (rejectors (N=48)/plasma: 720.96 pg/mL &plusmn 677.96 pg/mL versus controls (N=42), 213.60 pg/mL plusmn 160 pg/mL, p<0.0001; rejectors (N=47)/urine: 127.56 pg/mL plusmn 143.62 pg/mL versus controls (N=31), 39.61 pg/mL plusmn 29.86 pg/mL, p<0.001 Mann Whitney U test). In the lateral flow assay using spiked buffer a limit of detection was realizied. Samples from patients with a biopsy proven acute or chronic kidney rejection as well as samples of unsuspicious patients were already successfully applied with a reasonable sensitivity and specificity values >70&percnt.

Conclusions: In this study, the value of CXCL9 detection in plasma and urine of patients with TCMR and AMR after kidney transplantation was confirmed. Furthermore, a lateral flow assay as point of care test for CXCL9 was developed.

Abstract# 550

Novel Morphologic Biomarkers of Cardiac Allograft Remodeling are Associated with Multiple Peri- and Post-transplant Inflammatory Processes

C. Yuan[1], S. Arabyarmohammadi[1], H. Li[1], E. Peyster[2], P. Lal[3], M. Feldman[3], K. Margulies[2], A. Madabhushi[1], *[1]Department of Biomedical Engineering, Case Western Reserve University, Cleveland, OH, [2]Cardiovascular Research Institute, University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA*

Purpose: It has long been recognized that transplanted hearts develop a stiffened, restrictive physiology at an accelerated rate compared to native hearts. While this is thought to be due to a variety of factors which result in local inflammatory injury and subsequent remodeling. Inflammatory insults and their subsequent effects on in-situ tissue architecture have never been rigorously studied. In this work, we sought to use quantitative image analysis tools to measure a variety of morphologic biomarkers pertaining to collagen changes in a large cohort of endomyocardial biopsy (EMB) samples. We then apply these features to investigate the roles of several potential causes of inflammation (reperfusion injury, quilty lesions, and a history of cellular rejection) in the transplanted heart.

Methods: Given that the collagen in different regions have different responses to the causes of inflammation, a U-net model was trained to classify collagen into three types according to its location: collagen at the edge of the myocardium, collagen around myocytes, and collagen inside stroma. Collagen fibers were further segmented by utilizing a local binary pattern operator combined with OTSU algorithm. We then extracted a set of 216 biologically-inspired collagen features, relating to the density, morphology, spatial arrangement and interaction with myocytes. The relationship between 216 collagen features and the causes of inflammation were comparatively analyzed. Feature selection was employed to identify the most 5 predictive features on a set of 911 slides and these were subsequently trained with a random forest classifier to predict the existence of the causes of inflammation. The area under the receiver operating characteristic curves (AUCs) were calculated to evaluate the model performance on the test 395 slides.

Results: 1) The AUCs for predicting the existence of reperfusion injury, quilty lesions, and a history of cellular rejection reached 0.65, 0.61 and 0.81, respectively. This showed that collagen features were strongly linked to the causes of inflammation studied. 2) Different causes of inflammation showed different effects on the three types of collagen; quilty lesion mainly acted on the collagen at the edge of the myocardium, while reperfusion injury mainly acted on the collagen around myocytes. 3) Collagen features were more closely related to the historical rejection grade than the current rejection grade, indicating that the change of collagen features was a gradual accumulation process.

Conclusions: This work demonstrates that the novel biomarkers derived from collagen are highly potential for the mechanism-exploring of the causes of inflammation in remodeling of the transplanted myocardium.

Abstract# LB 28

Urinary Exosomal Cystatin C and Lipopolysaccharide Binding Protein as Biomarkers for Monitoring Antibody-mediated Rejection After Kidney Transplantation

M. Kim, S. Lim, S. Shin, *Department of Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of*

Purpose: This study aims to discover and validate urinary exosomal biomarkers for antibody-mediated rejection (ABMR) after kidney transplantation.

Methods: A total of 60 urine samples from kidney transplant recipients were collected at the time of check-up or 2 - 3 hours before the for-cause biopsy. In addition, urine specimens were collected from living kidney donors just before donor nephrectomy. They were classified into five groups; ABMR group (12 cases), T cell-mediated rejection (TCMR) group (8 cases), BK virus nephropathy (BKVN)

group (5 cases), no major abnormality (NOMOA) group (11 cases) and donor (DONOR) group (24 cases). Exosome was fractionated from patient's urine by stepwise ultra-centrifugation for proteomics analysis to find out biomarker candidates for ABMR. In the validation cohort, there were 25, 10, 19, and 25 recipients in the ABMR, TCMR, NOMOA, and control groups, respectively.

Results: Totally, 1,820 exosomal proteins were identified in the discovery set. Among those proteins, four biomarker candidates were selected for ABMR; Cystatin-C (CST3), serum paraoxonase/arylesterase (PON1), retinol-binding protein 4 (RBP4), and lipopolysaccharide-binding protein (LBP). In the validation cohort, Western blot analysis was performed to validate urinary exosomal biomarker candidates for ABMR. Urinary exosomal LBP in the ABMR group significantly increased compared with the other groups. In addition, urinary exosomal CST3 in the ABMR group significantly increased compared with the control and NOMOA groups whereas there was no significant difference between the ABMR and TCMR groups. Immunohistochemical staining showed that relative intensities of LBP and CST3 at glomerulus were significantly higher in the ABMR group compared with the NOMOA and TCMR groups.

Conclusions: In conclusion, urinary exosomal CST3 and LBP are potent biomarkers for ABMR after kidney transplantation.

Adjuvant Treatment Shapes the Bone Marrow Myeloid Compartment Towards an Immunosuppressive Phenotype That Can Suppress Allograft Rejection

J. Ge[1], E. Anderson[1], J. F. Markmann[2], A. Cuenca[1], *[1]Surgery, Boston Children's Hospital, Boston, MA, [2]Surgery, Massachusetts General Hospital, Boston, MA*

Purpose: Myeloid derived suppressor cells (MDSCs) expand in response to inflammatory stimuli and have been shown to suppress adaptive immunity. Preliminary data from our lab suggests that adjuvant treatment expands MDSCs that can suppress allograft rejection. We hypothesized that distinct phenotypic and functional changes occur in bone marrow myeloid compartment that lead to the production of MDSCs following adjuvant treatment.

Methods: C57Bl/6 mice were injected with 200 µl saline or alum intraperitoneally every other day for a total of 3 doses. Spleen, peripheral blood and bone marrow was examined at different time points via flow cytometry from either saline or alum treated mice. A separate aliquot of cells were stimulated with PMA (50 ng/mL) and ionomycin (1 ug/mL) and analyzed for the presence of IL-10 via flow cytometry.

Results: At 7 days post adjuvant treatment, we noted an expansion of common myeloid progenitors (0.28 ± 0.044% vs 0.108 ± 0.013%, p=0.009), macrophage and DC progenitors (0.053 ± 0.010% vs 0.023 ± 0.003%, p=0.034) and common monocyte progenitors (0.62 ± 0.080% vs 0.39 ± 0.033%, p=0.038) in the bone marrow compared to saline controls. In alum treated animals, both monocytic (m)-MDSCs and granulocytic (g)-MDSCs significantly expanded in bone marrow, spleen, and peripheral blood and demonstrated significantly lower expression of CX_3CR_1 but increased expression of PD-L1, suggestive of a more suppressive phenotype. To support this, alum treatment increased IL-10 production by both M-MDSCs (34.37 ± 4.26 vs 11.32 ± 2.18%, p=0.028) and G-MDSCs (28.6 ± 2.54 vs 5.88 ± 1.46 %, p=0.007) in response to PMA stimulation compared to saline controls

Conclusions: Adjuvant treatment skews the bone marrow myeloid compartment towards a potent suppressor phenotype. These data support our previous findings that adjuvant treatment can expand m-MDSCs and g-MDSCs that suppress adaptive immunity and allograft rejection. Our data suggest that adjuvants can be designed to selectively expand suppressor cell populations *in vivo* by shaping the bone marrow compartment. Further, this strategy could be utilized to condition transplant recipient preoperatively and decrease the significant morbidity associated with current immunosuppressive regimens.

Abstract# 552

Donor Kidney-Resident Macrophages Promote Allograft Inflammation and CD8 T Cell Response Post-Transplantation

A. Dangi[1], S. Yu[2], I. Husain[1], R. Geesala[1], X. Luo[1], *[1]Nephrology, Medicine, Duke University, Durham, NC, [2]Division of Organ Transplantation, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Purpose: Kidney-resident macrophages play important roles in maintaining normal kidney function and promoting prompt repair following kidney injuries. Nevertheless, their fate and role in kidney transplantation remain unknown.

Methods: Donor kidneys from BALB/c mice (CD45.2) were transplanted into bilaterally nephrectomized C57BL/6 (B6; CD45.1) recipients. Untreated transplant recipients were sacrificed at various time points to track donor kidney-resident macrophages. To investigate the role of donor kidney-resident macrophage, these cells were depleted by *treating BALB/c donors* with clodronate-liposomes (200 µl/mouse for a week) prior to the transplantation into B6 recipients (Clodro Group). A Control Group of B6 recipients received kidney allografts from BABL/c donors treated with control liposomes without clodronate. Post-transplant intragraft inflammation and cellular infiltration were determined using qPCR and FACS.

Results: In naïve untransplanted donor kidneys, resident macrophages were identified as $F4/80^{HI}CD11c^{INT}MHCII^{HI}CCR2^{-}$ cells, constituting ~25% of total $CD11b^{+}$ myeloid cells. Post-transplantation, the majority of these cells of donor-origin were eliminated by day7, and were undetectable by day15 in rejecting kidney allografts from untreated recipients. FACS analysis of graft-infiltrating *recipient* $CD45.1^{+}$ *monocytes/macrophages* from Control Group on day7 post-transplant revealed elevated expression of MHC II and co-stimulatory CD86. These cells also expressed elevated level of inflammatory cytokine TNFα measured by intracellular cytokine staining. qPCR analysis of allografts also demonstrated elevated levels of Il17a and Ccl8. Interestingly, all of these immune parameters were *significantly downregulated* in Clodro Group. In addition, the number of graft-infiltrating CD8 T cells also reduced significantly in Clodro Group in comparison to Control Group.

Conclusions: Our data demonstrate that donor kidney-resident macrophages may cause acute kidney allograft injury post-transplantation by promoting inflammation and CD8 T cell-infiltration. It is well recognized that acute kidney allograft-injury has detrimental effects on long-term transplant outcome. Thus, as a proof of concept our data suggest that targeting donor kidney-resident macrophages, probably during preservation time, may improve transplant outcomes.

Abstract# 553

Portal Hypertension Abrogates Trail Expression of Liver Resident Nk Cells via Il-33

Y. Imaoka, M. Ohira, K. Sato, H. Ohdan, *Hiroshima Uni., Hiroshima, Japan*

Purpose: Portal vein hypertension (PHT) is associated with poor prognosis, risk factors for small graft syndrome, bloodstream infection, and acute rejection after living donor liver transplantation. We have recently reported that liver-resident natural killer cells (lr-NK cells) activity reduced via IL-33 signal in PHT mice model, depending on tumor necrosis factor-related apoptosis-inducing ligand (TRAIL).To clarify the weakening mechanism of lr-NK cells' function, we focused on IL-33, a cytokine released as DAMPs, due to sinusoidal endothelial cell injury and hepatocyte injury caused by portal hypertension and blood flow disturbance, using a PHT mice model.
Methods: The right branch of the portal vein was selectively ligated as PHT mice model, and the left hepatic lobe on the non-ligated side was evaluated. The lr-NK cell activity was evaluated by flowcytometory, cytotoxicity test and expression analysis of IL-33 signaling in lr-NK cells by quantitative PCR method.
Results: (1) TRAIL expression of lr-NK cells improved in anti-IL-33 treated PHT model. ($p<0.05$, 5 mice per group). (2) The Ingenuity-based URA predicted that various pathways were differentially activated between TRAIL+ vs. TRAIL- NK cell subsets. Foxo1 and MAPK1 were detected as TRAIL-inhibited genes, which were reported to be induced by IL-33. (3) Akt-Foxo and MAPK signaling in lr NK cells were analyzed by qRT-PCR 1h after co-cultured with IL-33. mRNA expression of PI3K, MAPK1, Tbx-21 and EOMES in lr- NK cells increased 1h after co-cultured with IL-33. On the other hand, mRNA expression of Foxo1 and TNFSF10 in lr-NK cells decreased 1h after co-cultured with IL-33.
Conclusions: Akt-Foxo and MAPK signaling through IL-33/ST2 in lr- NK cells play a negative role on TRAIL expression of lr- NK cells in PHT mice.

Abstract# 554

Taurodeoxycholic Acid and L-valine Ameliorate Macrophage Driven Alloimmunity in Obese Transplant Recipients

M. Quante[1], J. Iske[1], D. Perkins[2], M. Alegre[3], H. Zhou[1], A. Elkhal[1], S. G. Tullius[1], *[1]Department of Surgery, Brigham and Women's Hospital, Boston, MA, [2]University of Illinois at Chicago, Chicago, IL, [3]Department of Medicine, The University of Chicago, Chicago, IL*

Purpose: Obesity initiates a chronic inflammatory network linked to more frequent perioperative complications and increased acute rejection rates after organ transplantation. Clinically, morbidly obese transplant candidates and recipients have undergone bariatric surgery facilitating transplantation. The effects of obesity on alloimmunity and transplant outcomes have not been defined.
Methods: We delineated the effects of obesity and bariatric surgery on alloimmunity and transplant outcomes in diet induced obese (DIO) mice. Performing allogeneic skin transplants in DIO recipient mice that underwent sleeve gastrectomies (SGx), we defined the interplay of innate and adaptive immune responses; quantitative metabolomic profiling in lean, DIO and DIO mice undergoing SGx delineated the effects of metabolic changes on alloimmunity.
Results: Skin transplants were rejected significantly earlier in completely mismatched DIO mice ($p<0.01$); DIO recipients of isogeneic transplants contained their grafts indefinitely. DIO recipients that underwent SGx prior to transplantation, in contrast, demonstrated significantly prolonged graft survival times ($p=0.05$); SGx also attenuated alloimmune responses including reduced Th1 and Th17 frequencies ($p<0.001$). Additional in-vitro studies identified ameliorated alloimmune responses with a reduced IFN-γ production and higher amounts of IL-10 by $CD4^+$ T cells in MLR ($p<0.01$). Through unbiased quantitative metabolomic profiling, we identified restored Taurodeoxycholic acid and L-Valine (TDCA/Valine) levels following SGx comparable to those in lean controls; in contrast, TDCA/Valine levels had been depleted in obese mice. Mechanistically, we identified restrained macrophage polarization through TDCA/valine via TGR5 signaling to inhibit $CD4^+$ T cell activation leading to a decreased production of IL-17 and IFN-γ in vitro and in vivo.
Conclusions: We provide novel insight into obesity induced inflammation and the consequences on allo-immunity and transplant outcomes. SGx initiated anti-inflammatory capacities on $CD4^+$ T cell driven allo-immune responses through compromised macrophage polarization. Restored TDCA/Valine levels simulated the effects of bariatric surgery, suggesting those metabolites as novel treatments ameliorating obesity augmented alloimmune responses.

Abstract# 555

Recipient Neutrophils Producing Myeloperoxidase Provoke Nk Cell and Monocyte/macrophage Activation During Acute Antibody-mediated Rejection of Kidney Allografts

D. Ueda, S. Miyairi, K. Keslar, W. M. Baldwin, R. L. Fairchild, *Lerner Research Institute, Cleveland Clinic, Cleveland, OH*

Purpose: Dysregulated donor-specific antibody (DSA) responses are induced in $B6.CCR5^{-/-}$ mice transplanted with complete MHC mismatched A/J kidney allografts and mediate acute graft rejection. Acute antibody-mediated rejection (AMR) also requires NK cell and myeloid cell activation to express effector functions within the graft.
Methods: This study used recipients deficient in myeloperoxidase (MPO) to test the influence of recipient myeloid cells on NK cell activation during acute AMR.
Results: $B6.CCR5^{-/-}$ recipients rejected A/J kidneys between days 18-25 vs. days 46-54 in $B6.CCR5^{-/-}MPO^{-/-}$ recipients, despite equivalent DSA titers. On day 15, NK cell activation to proliferate and express CD107a was markedly decreased within allografts in $B6.CCR5^{-/-}MPO^{-/-}$ recipients. RNA isolated from purified allograft infiltrating NK cells, monocytes and macrophages on day 15 post-transplant was interrogated by NanoString and indicated completely different transcript landscapes in all 3 leukocyte populations from $B6.CCR5^{-/-}MPO^{-/-}$ vs. $B6.CCR5^{-/-}$ recipients that correlated with development of acute vs. chronic allograft injury, respectively.
Conclusions: Neutrophil depletion abrogated NK cell activation and decreased macrophage infiltration into the allografts but increased monocytes producing MPO. Overall, the results indicate that neutrophils regulate graft-infiltrating NK cell activation and monocytes/macrophage development promoting acute AMR of kidney allografts.

Abstract# LB 34

CHBP Induces Stronger Immunosuppressive $CD127^+$ M-MDSC via Erythropoietin Receptor

C. Yang, *Urology, Zhongshan Hospital, Fudan University, Shanghai, China*

Purpose: Erythropoietin (EPO) is not only an erythropoiesis hormone, but also an immune regulatory cytokine. The receptors of EPO, $(EPOR)_2$ and tissue protective receptor (TPR), mediate EPO's immune regulation. Our group firstly reported a non-erythropoietic peptide derivant of EPO, cyclic helix B peptide (CHBP), which could inhibit macrophages inflammation and dendritic cells (DCs) maturation. As a kind of innate immune regulatory cell, myeloid-derived suppressor cells (MDSCs) share a common myeloid progenitor with macrophages and DCs. In this study, we investigated the effects on MDSCs differentiation and immunosuppressive function via CHBP induction.
Methods: MDSC differentiation and function was evaluated with or without CHBP stimulation. To compare the immune regulation difference of M-MDSC with or without CHBP stimulation, murine allo-skin transplant model was established. Signal pathways were detected by western blot, RNA-sequencing and protein array.
Results: CHBP promoted MDSCs differentiate toward M-MDSCs with enhanced immunosuppressive capability. Infusion of CHBP-induced M-MDSCs significantly prolonged murine skin allograft survival compared to its counterpart without CHBP stimulation. In addition, we found CHBP increased the proportion of $CD11b^+Ly6G^-Ly6C^{high}CD127^+$ M-MDSCs, which exerted stronger immunosuppressive function compared to $CD11b^+Ly6G^-Ly6C^{high}$ $CD127^-$ M-MDSCs. In CHBP induced M-MDSCs, we found that EPOR downstream signal proteins Jak2 and STAT3 were upregulated, which had strong relationship with MDSC function. In addition, CHBP upregulated GATA-binding protein 3 (GATA-3) protein translation level, which was an upstream signal of CD127 and regulator of STAT3. These effects of CHBP could be reversed if *Epor* was deficient.
Conclusions: Our novel findings identified a new subset of M-MDSCs with better immunosuppressive capability, which was induced by EPOR-mediated Jak2/GATA3/STAT3 pathway. These results are benefit for CHBP clinical translation and MDSC cell therapy in future.

Abstract# LB 35

Influence of Immunosuppressive Drug Trough Levels on Nk Cells in Liver Transplantation

R. Qin[1], J. Qin[2], C. Sun[3], B. Nashan[1], *[1]Clinic for Organ Transplantation, The First Affiliated Hospital of the University of Science and Technology of China, Hefei, China, [2]Clinic for Organ Transplantation, The First Affiliated Hospital of the University of Science and Technology of China., Hefei, China, [3]Division of Life and Medicine, University of Science and Technology of China, Hefei, China*

Purpose: Natural killer (NK) cells are enriched in lymphocytes within the liver and are considered to be main regulators of liver transplantation (LT) rejection and tolerance. However, the effects of immunosuppressants on NK cells are not clearly understood. The purpose of this study was to evaluate the impact of trough level conditions in long term patients on NK cell activation and function.

Methods: Peripheral blood mononuclear cells (PBMC) of 14 LT recipients and 14 healthy individuals (control) were used. Flow cytometry was done to analyse lymphocyte subsets and the phenotype of NK cells for in vivo and vitro. PBMC were exposed to single drugs [Everolimus(EVR), 5ng/ml; Sirolimus(SIR), 5ng/ml; Tacrolimus(TAC), 5ng/ml; Cyclosporine A (CSA), 125ng/ml; Mycophenolic acid (MPA), 15ug/ml; Steroid, 0.5ug/ml], and in typical combinations of [TAC, 0.5ng/ml + MMF, 15ug/ml + Steroid, 0.5ug/ml; TAC, 5ng/ml + SIR, 5ng/ml + Steroid, 0.5ug/ml; TAC, 5ng/ml + EVE, 5ng/ml + Steroid, 0.5 ug/ml] for 3 days. NK cells were sorted from PBMC under the same culture conditions, and RNA-seq was performed analysing genes for inhibition and activation.

Results: 1. Immunosuppressants reduced in vivo the number of CD4T, CD8T and NK cells, but did not change the percentage. For NK cells, the number of CD-56dimCD16+/- subgroups were mainly reduced. 2. It is worth noting that NK cells activity increased in LT 3. In vitro, Clinical drug treatment impaired the ability of NK cells to secrete interferon-r and perforin by flow cytometry and RNA- seq, and reduced expression of NKp44, CD69, NKG2D. In particular, no difference of NK cell activity was noted, when exposed to the three combination groups, despite their different impact on NK cells when exposed to the single drug.

Conclusions: This is the first time to use drug plasma concentrations simulating the clinical microenvironment in stable liver transplant recipients under in vitro conditions. Clinical drug treatment severely impairs NK cell activation and function. Despite of distinct actions on NK cells if given as single drugs, no differences are observed between all three different combinations of TAC neither with an mTOR nor MMF.

Abstract# LB 36

Naïve Rhesus Monkey CD4$^+$CD8^{lo}T Cells Comprise High Percentage of Memory T Cells with Strong Effector Function

M. Kubo, K. Sasaki, A. P. Gutiérrez, L. Lu, V. Vujevich, A. W. Thomson, M. Ezzelarab, *Department of Surgery, University of Pittsburgh, PITTSBURGH, PA*

Purpose: Human CD4$^+$CD8^{lo}T cells have been reported in patients with organ allograft rejection. We evaluated the incidence, phenotype, and function of CD4$^+$CD8^{lo}T cells in nonhuman primates (NHP).

Methods: Peripheral blood mononuclear cells (PBMC) were isolated from peripheral blood of naïve rhesus monkeys. The percentages of CD4$^+$CD8^{lo}T cells were evaluated. In comparison to CD4$^+$CD8^{neg}T cells, memory T cell (Tmem) subsets were evaluated based on their expression of CD45RA, CCR7, CD28, and CD95. Effector function was assessed by the production of interferon-gamma (IFNg) and tumor necrosis factor-alpha (TNFa). Cytokine production was also assessed after stimulation with allogeneic PBMC for 5 days. The mean fluorescence intensity (MFI) of T-box transcription factors T-bet and Eomesodermin (Eomes) was also assessed.

Results: In naïve rhesus monkeys, the percentage of CD4$^+$CD8^{lo}T cells in peripheral blood was 1.54±0.32%. In CD4$^+$CD8^{lo}T cells, CD45RA$^-$CCR7$^-$ effector Tmem (Tem) were 17.9±2.0%, compared to 11.3±1.1% in CD4$^+$CD8^{neg}T cells ($p<0.01$). CD45RA$^+$CCR7$^-$ terminally-differentiaed effector Tmem (Temra) were 25.3±4.2%, compared to 5.8±0.8% in CD4$^+$CD8^{neg} T cells ($p<0.01$). CD95$^+$CD28$^-$ Tem were 33.4±5.5%, compared to 4.0±0.8% in CD4$^+$CD8^{neg}T cells ($p<0.01$).The percentage of IFNg$^+$TNFa$^+$ T cells in CD4$^+$CD8^{lo}T cells was 28.6±3.1%, compared to 8.2±1.8% in CD4$^+$CD8^{neg} T cells ($p<0.01$) Notably, following allogeneic stimulation, IFNg$^+$TNFa$^+$ T cells were significantly higher in CD4$^+$CD8^{lo}T cells (22.7±3.3%) compared to CD4$^+$CD8^{neg}T cells (8.7±0.8%) ($p<0.01$). Additionally, CD4$^+$CD8^{lo}T cells exhibited significantly higher Eomes and T-bet expression (MFI= 95.6±3.7 and 588.7±87, respectively), compared to CD4$^+$CD8^{neg}T cells (MFI= 66.1±3.2, and 232.3±3.5, respectively) ($p<0.05$).

Conclusions: We show for the first time that under steady-state conditions, CD4$^+$CD8^{lo}T cells exhibit a higher memory profile and effector function in comparison to CD4$^+$CD8^{neg}T cells. These findings justify the evaluation of the role of CD4$^+$CD8^{lo}T cells in organ allograft rejection in NHP and their response to therapeutic intervention.

Abstract# 556

Effects of IL-18 on Key Post-Translational Modifications of Human Foxp3 and Innate Immunity

T. Akimova[1], L. M. Christensen[1], Z. Wang[2], M. H. Levine[2], W. W. Hancock[1], *[1]CHOP & University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA*

Purpose: Most of our ideas about Treg cells are extrapolated from findings in mice, with actual clinical data typically involving flow cytometric enumeration of CD4+FOXP3+ cells, with the implication that Treg cell numbers correlate with Treg function. However, FOXP3 is subject to many post-translational modifications that critically determine the function of Treg cells, and those modifications have not yet been studied in primary human Treg cells.

Methods: Tregs and plasma were isolated from healthy controls or patients listed for lung, liver or kidney transplantation (Tx). We studied FOXP3 protein by Taqman protein assay. In addition, in studies of lung ischemia/reperfusion injury (IRI), IL-18-treated or control Tregs from normal C57BL/6 mice were adoptively transferred into immunodeficient (Rag1-/-) mice.

Results: Obese (but not non-obese) patients listed for lung, kidney and liver Tx had impaired pre-Tx Treg suppressive function and increased levels of IL-18 compared to healthy individuals. In healthy donor Tregs, ~50% of FOXP3 protein was present as dimers and/or oligomers, ~25% of total FOXP3 was ubiquitinated, and ~80% of total FOXP3 was acetylated. Exposure of Treg cells to IL-18 led to a significant decrease of total FOXP3 protein level (~69% of initial levels) and a 2-fold reduction of FOXP3 dimerization and/or oligomerization; such assembly of FOXP3 into higher-ordered structures is critical for Treg function. We also observed a substantial increase of FOXP3 ubiquitination, but not FOXP3 acetylation, and increased TRAF6-STUB1 complexes, decreased TRAF6-FOXP3 complexes and increased STUB1-FOXP3 complexes in Treg after exposure to IL-18. UbiTest confirmed that in the presence of IL-18, FOXP3 ubiquitination was significantly increased, with increased K48-linked ubiquitination and STUB1 involvement. IL-18 also induced expression of the pro-inflammatory cytokines, IL-1β and IL-6, in Treg cells. In conjunction with increased FOXP3 ubiquitination and disrupted di- and oligomerization of FOXP3, the stability of FOXP3 expression under stimulatory conditions was significantly altered. Lastly, we assessed direct effects of IL-18 on Treg function in vivo using a murine IRI model. We found that adoptively transferred Tregs that had been pretreated with IL-18 were unable to prevent lung IRI, whereas control Tregs significantly suppressed such injury, revealing previously unknown direct effects of Tregs on the innate immune system.

Conclusions: We provide quantitative insights into human FOXP3 biology and how such parameters can be modulated by IL-18. The effects of IL-18 on Tregs have relevance to both the innate and adaptive immune systems, and for the pre-Tx evaluation of patients.

Abstract# 557

The Absence of T Follicular Regulatory Cells Prolongs Germinal Center Reactivity in Transplantation

E. S. Crichton, S. Zeng, I. Badell, *Emory University, Atlanta, GA*

Purpose: Deleterious alloantibodies result from T follicular helper (Tfh) cell-driven germinal center (GC) reactivity. T follicular regulatory (Tfr) cells are a subset of regulatory T cells that have been identified as important regulators of GC responses and antibody formation. However, whether Tfr cells regulate Tfh cells in vivo is unknown and little is understood of their role in transplantation. Thus given the potentially beneficial impact Tfr cells could have in controlling pathologic donor-specific antibody (DSA) responses, it is of great interest to understand their role in transplantation.

Methods: To examine the impact of Tfr cells in transplantation, we first utilized a full MHC mismatch murine skin allograft model to test for and define the kinetics of alloresponsive Tfr cells. We then used a conditional Tfr knockout (KO, $Bcl6^{fl/fl}Foxp3^{Cre}$) mouse to study the function of Tfr cells in response to BALB/c and OVA antigen mismatch skin grafts. Graft-draining lymph node (dLN) Tfh and GC B cell, and DSA responses in the absence of Tfr cells were evaluated in comparison to wild type (WT, $Bcl6^{fl/fl}Foxp3^{wt}$) controls. Tfh:B cell co-cultures, alloantibody subclass and affinity were also examined in the presence or absence of Tfr cells.
Results: Tfr cells were detected following transplantation, but the frequency and number of Tfr cells remained stable over time relative to the dynamic expansion and contraction of their Tfh cell counterparts. Tfr KO mice were confirmed by the absence of $CD4^+CXCR5^+PD1^{hi}Foxp3^+$ T cells. 10 days after primary Balb/c and OVA skin grafts, no significant differences were observed in the frequencies of Balb/c-reactive or OVA-specific Tfh cells (Figure 1) or $H2K^d$-specific or alloreactive GC B cells between WT and KO recipient mice. In Tfh:B cell co-culture studies there were no significant differences in class-switched B cell or IgG formation between WT and KO groups. Interestingly, 35 days following skin transplants, KO mice exhibited a greater frequency of Tfh cells (4.27 vs. 2.05, p=0.016) compared to WT mice in post-transplant dLNs (Figure 2). No differences were observed in the quantity (MFI and OD) or quality (antibody subclasses and affinity) of donor specific antibody formation.
Conclusions: These findings implicate Tfr cells in humoral alloreactivity and suggest an in vivo role for Tfr cells after transplantation in mediating GC reactivity. While their absence doesn't affect peak (d10) GC responses, it did significantly delay the contraction (d35) of GC Tfh cells. As such, Tfr cells may influence GC kinetics and the development of anamnestic alloimmunity that may manifest in secondary humoral responses.

Abstract# 558

Tip60 Inhibitors Enhance Regulatory T Cells (Treg) Induction by Promoting Acetylation of Foxp3

F. Fueyo-Gonzalez[1], G. Vilanova[2], M. Fribourg[1], *[1]Department of Medicine, Translational Transplant Research Center, Icahn School of Medicine at Mount Sinai, New York, NY, [2]LaCàN, Universitat Politècnica de Catalunya-BarcelonaTech, Barcelona, Spain*
Purpose: TIP60, a histone/protein acetyltransferase essential for multiple functions in the cell, is involved in Foxp3 acetylation in Treg. Acetylation protects Foxp3 from degradation, and acetylated Foxp3 translocates to the nucleus to activate the immunosuppressive transcriptional program. TIP60 inhibitors have been studied in the context of cancer, but their effect on Treg remains unknown.
Methods: We performed *in vitro* murine and human Treg inductions in the presence or absence of three TIP60 inhibitors (NU9056, MG149, and TH1834) and analyzed Foxp3 expression using flow cytometry, and Foxp3 acetylation using a proximity ligation assay.
Results: *In vitro* Treg induction cultures (murine and human) showed that TIP60 inhibitors augment the percentage of Foxp3+ cells in a dose-dependent manner (**Fig. 1A**). To address the molecular mechanisms we performed mathematical modeling that hypothesized an activating effect of TIP60 inhibitors through an increase of Foxp3 acetylation, which we then validated experimentally in our cultures (**Fig.1B**).
Conclusions: Our data newly indicate that TIP60 inhibitors have immunomodulatory properties with the potential to prolong allograft survival.

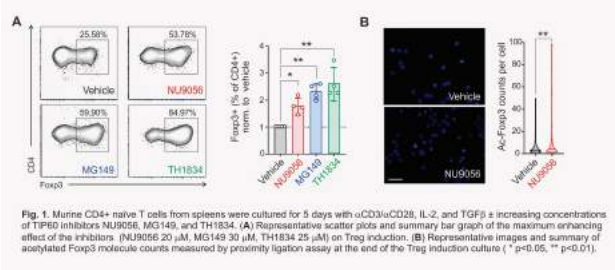

Fig. 1. Murine CD4+ naïve T cells from spleens were cultured for 5 days with αCD3/αCD28, IL-2, and TGFβ ± increasing concentrations of TIP60 inhibitors NU9056, MG149, and TH1834. (**A**) Representative scatter plots and summary bar graph of the maximum enhancing effect of the inhibitors (NU9056 20 μM, MG149 30 μM, TH1834 25 μM) on Treg induction. (**B**) Representative images and summary of acetylated Foxp3 molecule counts measured by proximity ligation assay at the end of the Treg induction culture (* p<0.05, ** p<0.01).

Abstract# 559

IL-10 Signaling in T Cells Modulates Costimulation-independent Activation and is Essential for Transplant Tolerance Induction

M. Iglesias Lozano[1], D. Bibicheff[1], M. Chicco[2], A. Komin[1], G. Brandacher[1], G. Raimondi[1], *[1]Plastic Surgery, Johns Hopkins University, Baltimore, MD, [2]Frimley Health NHS Foundation Trust, London, United Kingdom*
Purpose: Costimulation blockade (CoB)-based immunotherapy remains a very promising approach for better management of transplant recipients. Understanding the mechanisms that impact the efficacy of CoB is a necessary step toward translation into a clinically successful protocol. Integration of pro- and anti-inflammatory cues by T cells is now recognized to modulate their activation. We aimed at elucidating the role of direct IL-10 signaling in T cells in the outcome of CoB therapy.
Methods: Balb/c skin was transplanted to wt C57BL/6 (B6) or to B6 with T cells expressing a dominant negative IL-10 receptor which make them unresponsive to this cytokine (10R-DN). Recipients received peri-transplant donor specific infusion and three weekly anti-CD154 mAb administrations. Studies on effector T cells were conducted using in vitro activated polyclonal T cells that were then rested for 3 days.
Results: Unmanipulated 10R-DN recipients rejected their transplant with dynamics identical to wt B6. However, differently from wt B6, graft survival in 10R-DN could not be promoted by CoB (MST 105d vs 30d in the latter) revealing an unexpected important direct effect of IL-10 on T cells. This accelerated rejection correlated with increased production of TNF-a, IFN-g and IL-17A by T cells in spleen and draining lymphoid tissues of 10R-DN mice, in comparison to B6 recipients. Surprisingly, in vitro experiments of both TH differentiation and effectors reactivation showed that IL-10 did not significantly altered effector functions (cytokine secretion). Moreover, IL-10 did not alter the expression of important checkpoint receptors. We then tested if IL-10 could impact costimulation-independent T cell activation (recognized to afflict the efficacy of CoB). In vitro experiments clearly showed that IL-10 neutralizes the poorly investigated effect of TLR-mediated costimulation of naïve, effector, and memory T cells. We are now interested in deciphering the mechanisms behind such an important regulation.
Conclusions: Overall, these results reveal a previously unappreciated role of IL-10 signaling in T cells as pre-requisite for the therapeutic efficacy of CoB. Merged with the recognized plasticity of IL-10 signaling, this observation opens a novel

area of investigation that could reveal new "Achille's Heels" in the successful implementation of CoB and suggest complementary interventions for the actuation of robust immunoregulation.

Abstract# 560

Evaluation of the Differentiation Program of Endogenous Antigen-specific CD8$^+$T Cells Following Transplantation

S. M. Krummey[1], K. Tong[2], M. L. Ford[2], *[1]Pathology, Johns Hopkins University, Baltimore, MD, [2]Surgery, Emory Transplant Center, Atlanta, GA*

Purpose: Despite advances in the survival of transplanted organs, acute T cell mediated rejection remains a significant clinical problem with few effective or targeted treatments. The differentiation of naïve CD8$^+$ T cells into effector populations is governed by cues that occur during antigen priming. Therefore, understanding the characteristics of CD8$^+$ T cell differentiation in response to allogeneic antigen has the potential to uncover strategies that could selectively restrain donor-reactive T cell responses.

Methods: In order to gain a detailed understanding of the differentiation of endogenous CD8$^+$ T cells in response to allografts, we evaluated the C57BL/6 H-2(b) CD8$^+$ T cell response to an allogeneic H-2L(d)-restricted epitope (termed "QL9") using an MHC class I tetramer. Using a magnetic enrichment method, we established that the QL9/L(d) tetramer specifically stained naïve CD8+ T cells in a peptide-dependent manner.

Results: Following skin grafting with H-2L(d)-expressing Balb/c skin grafts, the absolute number of QL9/L(d)-specific CD44^{hi} CD8$^+$ T cells expanded approximately 10-fold relative to naïve mice, and nearly all of the CD44^{hi}QL9/L(d)-specific cells were Ki67$^+$ at day 10 in the draining lymph node and spleen. In infection models, the expression of KLRG-1 and CD127 (IL-7Rα) on effector CD8$^+$ T cell populations correlates with divergent cellular fates as either short-lived effectors (KLRG-1^{hi}CD127^{lo}) or memory T cells (KLRG-1^{lo}CD127^{hi}). We next evaluated the phenotype of QL9/L(d)-specific effector cells during the first two weeks post-graft. The expression of CD127 declined acutely at day 7 post-graft and was re-expressed by day 14, similar to the kinetics of expression on post-infection viral-specific CD8$^+$ T cells. However, in contrast to the high frequency of KLRG-1^{hi} short-lived effector cells that emerge post-infection, following skin grafting a very low frequency of QL9/L(d)-specific cells were KLRG-1^{hi} (avg. 4.4% and 8.5% in draining lymph nodes and spleen, respectively).

Conclusions: These results suggest that a significant portion of allogeneic short-lived effector CD8+ T cells have a KLRG-1lo phenotype that is distinct from the established population definitions. Future studies will investigate the subpopulations of KLRG-1lo QL9/L(d)-specific effector CD8+ T cells that have potent effector function, with the goal of identifying novel cellular pathways that might serve as effective therapeutic targets.

Abstract# 561

CD40/40L Pathway is Critical in Controlling CMV Transmission Following Kidney Transplantation in Immunocompromised Mice

X. Lai[1], L. Qiu[2], J. Wang[1], L. VanOsdol[1], S. Yan[3], M. Kandpal[4], M. Abecassis[5], Z. Zhang[1], *[1]Comprehensive Transplant Center, Microsurgery core, Northwestern University, Chicago, IL, [2]University of California,, San Francisco, CA, [3]Northwestern University, Chicago, IL, [4]Comprehensive Transplant Center, Northwestern University, Chicago, IL, [5]University of Arizona, Tucson, AZ*

Purpose: We have previously shown that transplant of kidneys from donor mice latently infected with murine cytomegalovirus (CMV) into naïve recipients treated with clinically relevant immunosuppression results in CMV reactivation and systemic dissemination. Our study is to determine the cellular and molecular mechanisms underlying CMV dissemination following kidney transplantation in immunocompromised recipients by blocking inflammatory mediators associated with transplant injury.

Methods: Kidneys from BALB/c mice latently infected with Smith murine CMV were transplanted to binephrectomized naïve immunodeficient NSG mice deficient of T cells, B cells and NK cell function. Recipients were treated with various extracellular mediator blockers, including anti-IL-1β, anti-IL-6 receptor, anti-IL-18 receptor, anti-CD40L, anti-TNFα, or a cocktail mixed with the above antibodies. At endpoints, kidney grafts, spleens, salivary glands and lungs were collected for CMV immediate early (IE) gene copy analysis and/or flow cytometry analysis.

Results: We observed that treatment with the cocktail antibodies resulted in a dramatic increase in viral DNA copies in the kidney grafts as measured on post-transplant day (POD) 28 and POD42, compared with the transplants treated with isotype controls. To determine the role of each individual inflammatory mediator in controlling post-transplant reactivation, the recipients were treated with a single monoclonal antibody against CD40L, IL-6, TNFα, IL-1β or IL-18. Interestingly, recipients received anti-CD40L treatment accelerated CMV reactivation and dissemination as a significant increase in DNA replication was observed in the kidney grafts as early as POD14, compared with recipients untreated or treated with the other antibodies. The increased DNA copies were also observed in distal organs such as salivary glands and lungs, indicating that blockade of CD40/CD40L signaling promoted CMV reactivation and dissemination at early stage after transplantation. Flow cytometry analysis exhibited that anti-CD40L treatment dramatically increased myeloid cells infiltration in kidney grafts, including both Ly6C$^+$CX3CR1$^+$ inflammatory macrophages and Ly6C$^-$CX3CR1$^+$ patrolling monocytes which are key vehicles of murine CMV dissemination, suggesting that blocking CD40/CD40L signaling enhanced influx of monocyte and macrophages, leading to accelerated CMV transition.

Conclusions: We conclude that CD40/40L signaling plays a pivotal role in controlling CMV transmission following kidney transplantation in immunocompromised recipients.

Abstract# 562

Laminins Differentially Regulate Tolerogenic T Cell Migration and Homing to Lymph Nodes

L. Li[1], M. Shirkey[1], W. Piao[1], Y. Xiong[1], V. Saxena[2], T. Zhang[1], J. Iyyathurai[2], R. Lakhan[1], R. Abdi[3], J. Bromberg[1], *[1]Surgery, UMB, Baltimore, MD, [2]CVID, UMB, Baltimore, MD, [3]Harvard University, Boston, MA*

Purpose: Laminin α5 (Lama5) and α4 (Lama4), which are produced by lymph node (LN) stromal cells, influence CD4 T cell migration and stimulation. We hypothesized that laminins may regulate entry of T cells to LNs, thereby determining intranodal distribution and channeling alloimmunity under tolerant and immune conditions.

Methods: The effects of Lama4 and Lama5 on mouse and human T cells were evaluated in static and shear flow transendothelial migration (TEM). Lama5 conditional knock out (KO) and Lama4 conditional KO mice, in which expression of these fibers was specifically deleted in fibroblastic reticular stromal cells, and littermate controls (WT) were adoptively transferred with CD4 T cells and regulatory T cells (Treg) to analyze their trafficking. WT and Lama5 KO recipients were treated with BALB/c donor-specific splenocytes (DST) and anti-CD40L mAb along with adoptive transfer of T cell receptor transgenic TEa CD4 T cells recognizing donor alloantigen.

Results: Lama4 promoted but Lama5 inhibited TEM of various T cell subsets, including murine CD4 and CD8 naïve, memory and effector cells, Treg, and human activated CD4 T cells and Treg, in both static and shear stress flow conditions. Lama5 receptors on T cells were shown to be α6 integrin and α-dystroglycan (αDG) and blocking either with specific mAbs attenuated Lama5 inhibitory effects. Transferred CD4 T cells and Treg had enhanced entrance to Lama5 KO LNs and reduced entrance to Lama4 KO LNs. Transferred cells localized to the T cell zone, particularly the cortical ridge (CR) and around high endothelial venules (HEV), where Treg are induced. Blocking Lama5 receptors also promoted CD4 and Treg entry into the CR. Under both immune and tolerance conditions, more alloantigen specific T cells trafficked through Lama5 KO HEV and CR, demonstrating the inhibitory role of Lama5 for migration and Treg induction. After transplantation, depleting stromal Lama5 promoted TEa cell differentiation toward Foxp3+ Treg and suppressed the differentiation toward IL-17+ Th17 cells.

Conclusions: Lama4 promoted human and murine T cell migration in homeostasis, immunity, and tolerant conditions. Lama5, through binding of the T cell adhesion receptors α6 integrin and αDG, inhibited T cell migration. Depleting stromal Lama5 promoted, while depleting Lama4 suppressed, CD4 T cell and Treg entrance into the LN, indicating laminins are efficient targets to modulate T cell trafficking and immunity to alter immune responses.

Abstract# 563

P2X7 Receptor Activity Mediates Th17-Specific Self- and Alloreactivity in Non-Human Primates

C. Little, J. Sullivan, W. Burlingham, D. Kaufman, *Department of Surgery, University of Wisconsin, Madison, WI*

Purpose: The broadly expressed ATP-binding purinergic receptor, P2X7 (P2X7R) is involved in the Th17 mediated cellular immune response to allo- and select self-antigens (Collagen type V [ColV], vimentin, kα1-tubulin). Inhibition of the P2X7R abates these responses without loss of Th1 mediated reactivity to bacterial/viral challenge. Normal regulation of these Th17 mediated responses is controlled by Tregs positive for CD39, an enzyme required for hydrolysis of extracellular ATP. Together these results identify the P2X7R as a promising target for selective inhibition of allogenic responses while preserving Th1 function. Importantly, naturally occurring functional polymorphisms conferring high and low pore activity exist in humans, which must be considered in therapeutic implementation of P2X7R inhibition. Based on these findings in humans, we sought to evaluate the role of the P2X7R in allo- and self-antigen responses in rhesus macaques (RMs) and to characterize the baseline functional polymorphisms within this species.

Methods: Flow cytometric analyses of YO-PRO-1 dye uptake and IL-17 production were utilized to determine pore activity and Th17 polarization, respectively. Trans-vivo delayed type hypersensitivity assays (tv-DTH) to evaluate immunologic response were performed using PBMC from RMs.

Results: Treg suppression via TGF-β neutralization or CD39 ATPase inhibition uncovered marked inflammatory responses to Col V, kα1-tubulin, and vimentin. Treg depletion, in lieu of molecular neutralization, similarly unmasked reactivity to these antigens. Importantly, the uncovered inflammatory responses were fully abrogated when performed in the presence of the P2X7R inhibitor, AZD9056. Compared to the baseline P2X7R functional polymorphisms observed in humans, RMs demonstrated similar population-level frequencies of high and low P2X7R pore activity. Furthermore, we found that high pore activity was associated with increased Th17 polarization, via enhanced IL-17 production by CD4+ T-cells.

Conclusions: As observed in humans, RM P2X7R activity is involved in uncovered, Th17 specific cellular immune responses. Importantly, by revealing functional polymorphisms consistent with human variations, we validated their rigor as a preclinical model for P2X7R-targeted therapies. Based on these findings, we hypothesize that low pore activity is associated with a tolerogenic state and that P2X7R inhibition could enhance tolerance induction protocols. Studies are ongoing within our renal transplant tolerance model evaluating P2X7R activity and T-cell polarization.

Abstract# 564

Single Cell RNAq-seq Analysis of Paired Peripheral and Intragraft T Cells Reveals Biopsy Specific Fc Receptor Gene Expression in Rejection Only

A. Malone, A. Leckie-Harre, I. Silverman, A. Chadha, H. Wu, B. Humphreys, *Washington University School of Medicine, St Louis, MO*

Purpose: Antibody mediated rejection (AMR) remains one of the major causes of allograft failure and our understanding of this disease process is poor. Transcriptomics studies have suggested antibody binding to Fc receptors plays a role in allograft injury by triggering T cell and NK cell activation in AMR. We performed single cell RNAseq on paired peripheral blood and biopsies from patients with AMR and non-rejection focusing on T cells and Fc receptor expression.

Methods: The 10X Genomics platform was used to make libraries which were sequenced to a depth of ~50k reads/cell. Gene-cell matrices were obtained from CellRanger and the downstream analysis (clustering, integration analysis, expression analyses) were done using R, Seurat and Monocle2. This study had IRB approval.

Results: 16086 immune cells in total (avg = 1124 genes/cell) from 5 kidney transplant patients (biopsy and pbmc's) were included in the final integrated analysis using UMAP. All major kidney cell types were identified including macrophages, B cells and T cells. T cells from rejecting samples (2442 T cells) and non-rejecting samples (2971 T cells) were subset for further analysis. A pseudotime analysis using Monocle2 was performed on these T cell subsets. We examined the expression of the Fc receptor genes, *FCGR3B, FCGR2A, FCGR3A, FCGR1A, FCGR2C*. We found that only *FCGR3A* (CD16a) varied with pseudotime and that expression increased from peripheral T cells to intragraft T cells in AMR patients only.

Conclusions: Our study find that *FCGR3A* expression is increased in T cells in AMR and is specific for the local environment of the allograft. These data confirm intragraft T cells as the source *FCGR3A* expression previously suggested in microarray based studies.

Abstract# 565

Establishing a Linear Program for the Development of Costimulation Resistant T-Cells

D. P. Moris, A. Lucander, A. Kirk, *Surgery, Duke, Durham, NC*

Purpose: CD4+CD57+PD1-T-cells are primed effectors capable of mediating belatacept-resistant rejection, however, the developmental program giving rise to these cells has not been elucidated in detail. We hypothesized that upon stimulation, naïve T-cells begin down an anticipatable path that progressively reduces their need for CD28-B7 costimulation and endows them with a phenotype of belatacept resistance.

Methods: Peripheral blood mononuclear cells were cultured in vitro from healthy volunteers. Cultures were stimulated with Human 4-1BB/TNFRSF9/CD137 Antibody(10 ug/ml) and Human OX40 Ligand/TNFSF4 Protein, Fc Tag(10 ug/ml). Cells were also cultured in the presence or absence of interleukin 15(IL-15) and stimulated or non-stimulated with 4-1BB and OX40 costimulation. Immunosuppression such as tacrolimus(10ng/ml), rapamycin(10ng/ml) and belatacept(125ug/ml) was added on day 0 of the culture.

Results: Cultures were exogenously stimulated with OX40 and CD137 before(B) or after(A) day 2. Exogenous IL-15 was administered after day 3. Conditions such as CD137B/OX40A and OX40A+CD137 after day 3+IL-15 were equally effective and generated the highest count of CD4+CD57+PD1- T-cells by day 5 ($p<0.05$ to all comparisons, Fig 1a). Stimulated cells with OX40A+CD137 After day 3+IL-15 demonstrated a rapid increase of CD4+CD57+PD1- cells after day 3 under belatacept, trend that was similar to the one found in the no immunosuppression group. Under tacrolimus and rapamycin treatment, the absolute counts of CD4+CD57+PD1 cells remained remarkable low (Fig. 1b). Similarly, CD4+CD57+PD1+ cells were also resistant to belatacept treatment but sensitive to tacrolimus and rapamycin effects(Fig. 1c). However, CD4+CD57- cells were sensitive to belatacept effect showing similar kinetics to those under tacrolimus and rapamycin(Fig. 1d).

Conclusions: In this study it was shown that following TCR stimulation and appropriate costimulation, OX40 and CD137 play integral roles in the development of CD57+ cytotoxic CD4 T-cells. This maturation scheme is linear and anticipatable, and the movement from costimulation dependence to independence involves specific, time-dependent signals, which lead to tractable changes in surface molecule expression that may have prognostic and therapeutic value.

Abstract# 566

K562 Cells Expressing HLA-A2 Stimulate Alloreactive CD8+ T Cells

A. B. Morris, E. Peek, A. Hadley, C. P. Larsen, *Emory Transplant Center, Emory University, Atlanta, GA*

Purpose: T cell-mediated rejection is a significant factor that leads to graft damage and loss in transplant recipients. Due to the complexity of the TCR:pMHC interaction, prediction of alloreactive T cells is difficult, and there are no widely available methods to measure alloreactive T cell responses at the allele level in a given recipient.

Methods: To understand the phenotype and function of alloreactive T cells, we developed an *in vitro* system to detect HLA-A2-alloreactive CD8+ T cells using K562 cells that express the HLA Class I molecule HLA-A2:01 and the costimulatory molecule CD86.

Results: Using these K562-A2$^+$ cells, we find that HLA-A2-negative individuals harbor a mean precursor frequency of 1.53% (n=5) of alloreactive T cells against HLA-A2-expressing K562 cells. Furthermore, these alloreactive HLA-A2-specific CD8$^+$ T cells exhibited a ~30-fold expansion in culture, indicating robust divisional capacity. Monoclonal antibody treatment blocking anti-HLA-A2 (clone BB7.2) completely abrogated proliferation of CD8$^+$ T cells by these K562-A2$^+$ stimulator cells as detected by Cell Trace Violet (CTV) dilution (25% CTV^{lo} vs 2%), confirming HLA-A2 allospecificity. In addition to their specificity to HLA-A2, T cell proliferation depended on costimulatory molecule CD86, as therapeutic blockade with anti-CD86 completely abrogated proliferation in HLA-A2 negative individuals (1% CTV^{lo}). Phenotypically, we find that the majority of HLA-A2 allospecific cells detected by proliferation are CD45RA$^-$CCR7$^-$ (Tem) or CD45RA$^-$CCR7$^+$ (Tcm), and >90% express the IL-2Ra as detected by CD25. As these phenotypes are likely due to their activation and not reflective of their initial state, further sorting experiments will determine from which subset allospecific cells reside.

Conclusions: Based on these data, we hypothesize that use of this *in vitro* system will allow for the detection and expansion of alloreactive T cells in transplant recipients. Further work elucidating the peptides presented by these K562-A2$^+$ cells will contribute to novel tools that will aide our understanding of the presence, phenotype, and function of alloreactive T cells in transplant recipients.

Abstract# 567

CD80/PD-L1 Uniquely Regulates CD4 Effector T Cell Migration

W. Piao[1], L. Li[1], Y. Zhang[2], K. Hippen[2], M. WillsonShirkey[1], B. Blazar[2], L. Riella[3], J. Bromberg[1], *[1]U Maryland, baltimore, MD, [2]U Minnesota, Minneapolis, MN, [3]Harvard U, boston, MA*

Purpose: CD80 is a costimulatory molecule expressed on antigen presenting cells (APCs) that binds CD28 and CTLA4, stimulating or inhibiting immunity, respectively. CD80 also binds Programmed Death-1 Ligand (PD-L1) to transduce coinhibitory signals for T cell activation. Blockade of PD-L1-CD80 with anti-PD-L1 exacerbates allograft rejection, while anti-CD80 mAb has inhibitory and stimulatory effects, suggesting additional mechanisms for regulation of immunity by this interaction. Notably, CD80 is highly expressed on activated effector CD4 T cells (Teffs), and PD-L1 is highly expressed by lymphatic endothelial cells (LEC). We tested whether Teffs-LEC CD80/PD-L1 signaling regulates Teffs function, including lymphatic transendothelial migration (TEM).

Methods: Human and mouse activated effector CD4 T cells were migrated across human or mouse LEC. Anti-CD80 and anti-PD-L1 mAbs or recombinant CD80-Fc and PD-L1-Fc were used to block or stimulate CD80 or PD-L1 on T cells and LEC. Their effects were assessed for cell signaling and in vitro and in vivo migration.

Results: Teffs expressed high levels of CD80. Blockade of CD80 on human or mouse Teffs with anti-CD80 mAb (1G10), which interrupts CD80 binding to PD-L1, inhibited human or mouse Teffs TEM in vitro and in vivo. PD-L1-Fc engagement of Teffs CD80 promoted Teffs TEM. Engagement of CD80 on Teffs with immobilized PD-L1Fc suppressed the constitutive phosphorylation of ERK without a specific effect on NFκB or Akt phosphorylation. Blocking LEC with anti-mouse PD-L1 mAb (10F.2H11) which blocks only the CD80-PD-L1 interaction, inhibited Teffs but not regulatory T cell (Treg) TEM. Crosslinking LEC PD-L1 with CD80-Fc induced strong phosphorylation of ERK, modest classical NFκB activation, but did not signal to Akt. CD80 engagement of LEC PD-L1 also enhanced VCAM-1 expression, which is important for TEM, and this increased expression was inhibited by blocking both classical NFκB and ERK signaling. Notably, LEC VE-cadherin expression, which is also important for TEM, was not affected by PD-L1 ligation by CD80-Fc.

Conclusions: Teff but not Treg uniquely use the CD80/PD-L1 to regulate TEM. Teff CD80 signals through classical NFκB and ERK pathways to enhance LEC expression of the VCAM-1 adhesion molecule. These data demonstrate a novel role for Teffs CD80 and LEC PD-L1 in regulation of lymphatic migration and provide new pathways for regulating immunity and understanding checkpoint molecules and blockade.

Abstract# 568

CRISPR Screens to Map CTLA-4 Regulatory Networks in Primary Human T Cells

O. Shaked[1], J. Freimer[1], J. Pritchard[2], A. Marson[1], *[1]UCSF, San Francisco, CA, [2]Stanford University, Stanford, CA*

Purpose: For most cell types, the pathways that regulate the levels of critical disease-relevant genes are not known. Recent advances in gene editing have enabled us to perform large-scale perturbation experiments in primary human T cells, allowing for identification of key regulators of disease relevant genes which may have applicability in modulating the transplant immune response.

Methods: Using a CRISPR loss-of-function screen, we identified transcription factors that regulate levels of CTLA-4, a checkpoint inhibitor found on regulatory T cells as well as activate conventional T cells that is the target of Belatacept. We created a library of 6000 guide-RNAs which target 1349 genes (generally 4 guides per gene), and 600 control guides. Results were validated using ribonucleoprotein knockouts of individual genes of interest.

Results: Fifty-nine genes significantly regulate the levels of CTLA-4 (FDR < 0.05, Figure 1), 23 of which decrease levels of CTLA-4, while 36 increase CTLA-4. The majority of these hits were validated using an independent arrayed validation strategy (Figure 2).

Conclusions: CRISPR screens can be used to map regulatory networks that control protein levels of critical factors that mediate the immune response in primary human T cells. We identified both canonical and novel regulators of CTLA-4. These data may help elucidate variances in regulation that could explain phenotypic differences seen in the clinical setting among well-matched recipients who experience heterogeneous outcomes. As gene editing moves into clinical practice, understanding key regulators of the immune system will be critical in selecting appropriate targets for therapeutic intervention.

Abstract# 569

Anti-CD272 Antibody (6B2) Generated Foxp3$^+$Regulatory T Cells and Suppressed Donor Specific Antibody in Murine Cardiac Transplant Model

Y. Yamamoto[1], M. Uchiyama[2], K. Uchida[3], H. Yagita[3], M. Niimi[1], *[1]Department of Surgery, Teikyo University, Tokyo, Japan, [2]Department of Cardiovascular Surgery, Teikyo University, Tokyo, Japan, [3]Juntendo University, Tokyo, Japan*

Purpose: The co-inhibitory receptor B and T lymphocyte attenuator (BTLA; CD272) has been implicated in the regulation of autoimmune and may potentially play an important role in alloimmune responses. We investigated the effects of agonistic anti-BTLA monoclonal antibody (6B2) on alloimmune responses in a murine model of cardiac allograft transplantation.

Methods: CBA mice ($H2^k$) underwent transplantation of C57BL/6 ($H2^b$) hearts and received four doses of 6B2 on day 0, 3, 6 and 9. Adoptive transfer study, flow cytometry study, and immunohistochemical (IHC) study were performed .

Results: Untreated CBA recipients rejected C57BL/6 cardiac grafts acutely (median survival time [MST], 7 days). CBA recipients exposed with four doses of 6B2 significantly prolonged allograft survival (MST, >100 days). Secondary CBA recipients given whole splenocytes from primary 6B2-exposed CBA recipients with beating B6 cardiac allografts 30 days after transplantation had prolonged B6 allograft survival (MST, >100 days). Histological studies showed that cardiac allografts from 6B2-exposed recipients had sparse cell infiltration and only slight myocardial damage and IHC showed more CD4$^+$Foxp3$^+$ cells in myocardiumon on day 30 after transplantation. Additionally, flow cytometry studies show an increased CD4$^+$CD25$^+$Foxp3$^+$ cell population in splenocytes from 6B2-exposed recipients and suppressed donor specific antibody (DSA) on day 30 and 100 after transplantation.

Conclusions: 6B2 could induce the prolongation of fully MHC-mismatched cardiac allograft through an increase of CD4$^+$CD25$^+$Foxp3$^+$ regulatory T cells and consequently the suppression of DSA.

Abstract# 570

Alloreactive Memory T Follicular Helper Cells Rapidly Differentiate Into Effectors Independent of B Cell Memory Following Retransplantation

S. Zeng, E. S. Crichton, I. R. Badell, *Department of Surgery, Emory, Atlanta, GA*

Purpose: Donor-directed HLA antibodies are an important cause of renal allograft injury, but effective therapeutic options to prevent or eliminate donor-specific antibodies (DSA) do not exist. Current therapies primarily target B lineage cells or center around alloantibody removal without focus on T follicular helper (Tfh) cells, the lineage of CD4+ T cells required for the provision of B cell help to generate mature antibody responses. Tfh cells drive de novo antibody formation and can differentiate into memory, but little is known about the role of memory Tfh (mTfh) cells in mediating humoral recall responses in transplantation. Thus, determining whether mTfh cells can accelerate humoral alloresponses and the factors influencing this process will guide strategies to combat HLA antibodies.

Methods: To examine the mTfh cell alloresponse we utilized a full MHC mismatch BALB/c to B6 murine skin allograft model. Naïve B6 recipients were grafted BALB/c skin, allowed to reject, and then re-grafted BALB/c skin 4-6 weeks after rejection of the primary graft. Graft-draining lymph node (DLN) and serum analyses were performed to measure cellular and humoral recall responses. To determine whether memory responses were mTfh cell-mediated and examine the role of endogenous B cell memory, sorted Balb/c-sensitized congenically-marked Tfh cells were adoptively transferred into naïve B6 mice that were then grafted BALB/c skin and their DLNs examined post-transplant. Tfh cells were also transferred into T cell deficient mice (Tcra KO) to isolate memory from the endogenous primary response.

Results: DLN analyses of Balb/c sensitized mice following skin graft re-challenge revealed accelerated Tfh cell, germinal center (GC) B cell and DSA responses compared to the primary response in skin-grafted naïve controls. These rapid memory responses were alloreactive in that they occurred upon rechallenge with Balb/c but not syngeneic B6 skin grafts. Memory Tfh cells adoptively transferred into naïve B6 mice without B cell memory exhibited rapid differentiation into effector Tfh cells compared to naïve CD4+ T cell controls 5 days after Balb/c skin-grafting. Transfer of mTfh cells into Tcra KO mice incapable of a primary T cell response and devoid of B cell memory also resulted in accelerated effector Tfh cell differentiation.

Conclusions: In sum, mTfh cells independent of B cell memory and primary T cell responses exhibit accelerated effector Tfh cell differentiation following repeat alloantigen exposure via transplantation. These findings support further elucidating the role of mTfh cells in recall humoral alloresponses, as their anamnestic qualities could have important diagnostic and therapeutic clinical implications.

Abstract# 571

Distinct Phenotype and Function of Antibody-suppressor Cxcr5$^+$Cd8$^+$ T Cells

J. Zimmerer, J. Han, M. Hart, S. Chaudhari, C. Peterson, G. Bumgardner, *OSU, Columbus, OH*

Purpose: We have reported that the novel subset of antibody-suppressor CD8$^+$ T cells (termed CD8$^+$ $T_{Ab\text{-}supp}$ cells) require the expression of CXCR5. In addition, alloprimed CXCR5$^+$CD8$^+$ $T_{Ab\text{-}supp}$ cells inhibit production of alloantibody (but do not reject allografts) while CXCR3$^+$CD8$^+$ T cells reject allogeneic transplants (but

do not inhibit antibody). Recent report demonstrates that there are many subsets of $CXCR5^+CD8^+$ T cells with different effector function including anti-viral, anti-tumor, anti-autoimmune, or antibody enhancers. By investigating $CD8^+$ $T_{Ab\text{-}supp}$ cell protein and transcript expression, we aim to determine a profile that might distinguish this novel $CD8^+$ $T_{Ab\text{-}supp}$ cell subset.

Methods: C57BL/6 (wild-type; WT; H-2^b) were transplanted with FVB/N (H-2^q) hepatocytes. On day 7 (peak activation of $CD8^+$ $T_{Ab\text{-}supp}$ cells), splenic $CXCR5^+CD8^+$ T cells were evaluated by RNA-seq and flow cytometry. Alloprimed $CXCR5^+CD8^+$ T cells were compared to naïve $CD8^+$ T cells as well as alloprimed $CXCR3^+CD8^+$ T cells. Fluorescence minus one controls were used to determine background staining (flow cytometry).

Results: RNA-seq analysis show that 1670 transcripts were upregulated or downregulated when comparing between flow sorted alloprimed ($CD62L^-CD44^+$) $CXCR5^+CD8^+$ T cells and naïve ($CD62L^+CD44^-$) $CD8^+$ T cells. Transcripts of note include Bcl-6 (3.3-fold upregulated), CXCR3 (8.4-fold downregulated), and S1pr3 (140-fold upregulated). The latter suggests an important role for S1PR3 on $CXCR5^+CD8^+$ $T_{Ab\text{-}supp}$ cell trafficking into the circulation, perhaps from the germinal center. Flow cytometry analysis suggests that $CD8^+$ $T_{Ab\text{-}supp}$ cells are short-lived effectors cells based on the expression of CD44, KLRG1, and CD122 (not CD62L or CD127). An expansive flow analysis panel (not shown, and review of the literature) comparing differences in transcript and protein expression between alloprimed, antibody-suppressor $CXCR5^+CD8^+$ $T_{Ab\text{-}supp}$ cells and other reported $CXCR5^+CD8^+$ T cell subsets indicates that the absence of PD-1, IL-10 and FoxP3 expression distinguishes $CD8^+$ $T_{Ab\text{-}supp}$ cells from all reported $CXCR5^+CD8^+$ T cell subsets (including $CD8^+$ T_{reg} and $CD8^+$ T follicular regulatory cells).

Conclusions: The phenotype of novel $CXCR5^+CD8^+$ $T_{Ab\text{-}supp}$ cells suggests cytotoxic $CD8^+$ T cells with short-lived effector function.

Abstract# LB 37

Proteomic Analysis of Extracellular Vesicles Derived From a Potent Donor-specific Regulatory T Cell-enriched Population Demonstrates Multiple Markers of Immune Suppression

B. Schreiber[1], S. Tripathi[1], M. Blaser[2], T. Pham[2], S. Kuraoka[2], S. A. Singh[2], E. Aikawa[2], A. Chandraker[1], *[1]Transplantation Research Center, Renal Division, Brigham and Women's Hospital, Boston, MA, [2]Center for Interdisciplinary Cardiovascular Sciences, Division of Cardiovascular Medicine, Brigham and Women's Hospital, Boston, MA*

Purpose: Extracellular vesicles (EVs) are emerging as vital mediators of intercellular communication and immune regulation. Regulatory T cells (Tregs) play an integral role in immune suppression and are both avid EV secretors and acquirers. However, the challenges of expanding human Tregs *ex vivo* and isolating pure EVs have limited molecular investigations largely to their microRNA cargoes. Using EVs isolated from donor Antigen-Specific T cell-enriched immune-Regulatory cell Lines (ASTRLs) with known suppressive function, we performed an in-depth proteomic analysis of Treg EVs and identified pathways of EV-mediated immune suppression.

Methods: ASTRLs were expanded *ex vivo* from peripheral blood mononuclear cells (PBMCs) of 4 transplant recipients prior to EV isolation/characterization from culture media via differential ultracentrifugation and nanoparticle tracking analysis (NTA). Global proteomics was performed by liquid chromatography-mass spectrometry; statistical analysis/visualization was completed in Qlucore Omics Explorer. Gene ontology (GO), pathway over-representation and protein-protein interaction (PPI) network analyses was performed using Consensus Path DB and STRING, respectively. ATPase functional capacity was assessed with a commercial kit.

Results: Of the 1,704 unique proteins identified, 848 were known to be EV-associated. NTA confirmed isolated particle size was consistent with that of EVs (mean diameter 133.9 +/- 3.1 nm). 89 differentially expressed proteins were detected between PBMC and ASTRL-derived EVs, 35 of which were over-represented in ASTRL-EVs ($q \leq 0.05$, fold-change >2; Figure 1). Enrichment analysis of those 35 proteins revealed significant over-representation of pathways involved in immunity, including negative regulation of T cell activation, antigen receptor signaling, and ATP hydrolysis coupled transmembrane transport. PPI network analysis with unbiased clustering identified 7 local network clusters (Figure 2), including those associated with ATP hydrolysis. ATP hydrolysis assay confirmed functional EV ATPase capacity.

Conclusions: These findings provide insight into Treg EV-mediated mechanisms of immune suppression, suggest EVs play a key role in the Treg response, and implicate ATP hydrolysis as a putative mechanism.

Abstract# 572

Estrogen Receptors Alpha and Beta are Required for Immune Homeostasis and Normal Treg Function

L. M. Christensen[1], T. Akimova[2], G. Ge[3], R. Han[1], L. Wang[1], P. Hernandez[3], C. O'Brien[3], M. H. Levine[3], W. W. Hancock[1], *[1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA*

Purpose: Estrogen signaling is a critical component of mammalian homeostasis, acting through a complex and interconnected system of hormone synthesis pathways and receptor signaling cascades. Estrogen signaling is thought to play a role in nearly every cell type throughout the body, including cells of the immune system. However, the interactions and functions of estrogen signaling within the immune system have yet to be elucidated.

Methods: We investigated the roles of estrogen receptor-alpha (ER-a) and estrogen receptor-beta (ER-b) in host T cells by undertaking their conditional deletion in adult mice, using floxed genes and tamoxifen-inducible Cre.

Results: In the absence of ER-b, secondary lymphoid organs had increased proportions of CD4+ cells (ranging from 15-33%; $p<0.05$). Ratios of T effectors to T regulatory cells (Tregs), and follicular T effectors (Tfh) to follicular Tregs (Tfreg) were drastically increased within the spleens (48% increase of Tfh:Tfreg; $p=0.0029$), superficial lymph nodes (sLNs) (29% with $p=0.0049$ and 68% with $p<0.0001$, respectively), and mesenteric lymph nodes (mLNs) (26% with $p=0.04$ and 42% with $p=0.0002$, respectively). Germinal Center B cell proportions were increased in both lymph node types (sLNs by 80% with $p=0.046$; mLNs by 30% with $p=0.049$). Specifically in the mLNs, ER-b KO resulted in significantly higher proportions of follicular B cells (54% with $p<0.0001$), in addition to follicular type I and type II cells (53% with $p<0.0001$ and 63% with $p=0.0001$, respectively). ER-b KO mice also had decreased proportions of Tregs and Tfregs most prominently in the mLNs (37% with $p<0.0001$ and 60% with $p=0.0014$, respectively). While ER-a KO mice had fewer and less pronounced differences in immune cell proportions compared to WT, notably there were significantly less Tregs (31% with $p=0.0007$) in mLNs and their Tregs had decreased suppressive function *in vitro*.

Conclusions: These data show that in the absence of estrogen signaling via ER-a or ER-b, cells within secondary lymphoid organs display inflammatory phenotypes, especially within the mLNs. In addition, these data suggest a potential role for estrogen signaling in influencing a tolerogenic immune environment suitable for transplantation. We are now undertaking studies to assess the effects of ER-a and ER-b deletion on allograft survival.

Abstract# 574

Selective Bcl-2 Inhibition to Deplete Hematopoietic Stem Cells in Bone Marrow Niche: A Novel Approach to Promote Mixed Chimerism

T. Hirose[1], H. Sasaki[1], G. Lassiter[1], D. Ma[1], T. Oura[1], A. Dehnadi[1], A. Cosimi[1], P. Cippa[2], T. Fehr[2], T. Kawai[1], *[1]Center for Transplantation Sciences, Massachusetts General Hospital, Boston, MA, [2]Institute of Physiology, University of Zurich, Zurich, Switzerland*

Purpose: A recent murine study has shown that successful mixed chimerism is achievable without myelosuppressive treatments by Bcl-2 inhibition. However, the mechanism by which selective Bcl-2 inhibition promotes chimerism was unclear. Since Mcl-1, not Bcl-2, has been reported as a major survival factor for hematopoietic stem cells (HSC), Bcl-2 inhibition is not supposed to deplete HSCs to open a space in the BM niches for allogeneic HSC engraftment. We therefore, tested Venetoclax, an FDA approved a highly selective Bcl-2 inhibitor, to evaluate whether selective Bcl-2 inhibition alone can deplete HSCs in BM niches. Venetoclax was then included in our conditioning regimen for combined BM and kidney transplantation (KTx) with only half dose (1.5Gy) of total body irradiation (TBI) previously required (3 Gy) to induce mixed chimerism.

Methods: Cynomolgus macaques were treated with 10 mg/kg of Venetoclax for 5 days. BM cells were serially aspirated to evaluate HSC (CD34+CD90+CD45RA-) depletion. Expression of apoptotic cascade proteins (BAX, Cytochrome C, Caspase-3, -7, and -9) on BM cells were also evaluated by flow cytometry. Finally, peri-transplant administration of Venetoclax (10mg/kg for 11 days) was added to our standard conditioning regimen (TBI, thymic irradiation, anti-CD154 mAb, ATG and a one month course of CyA) for combined BM transplantation (BMT) and KTx but with reduced (1.5Gy) TBI.

Results: After Venetoclax treatment, expression of Caspase-7 and -9 in HSC was significantly increased (167 ± 25% and 135 ± 6%; $p<0.01$ and $p<0.001$; Fig. 1a). As a result, HSCs were significantly depleted to 36 ± 15% of baseline levels (Fig.1b). In peripheral lymphocytes, expression of those apoptotic proteins in T cells, B cells, and NK cells also remarkably increased. With 1.5Gy TBI without Venetoclax in our conditioning regimen for BMT, no chimerism was induced in all four recipients and three rejected kidney (58, 100 and 167days). In contrast, all five BMT recipients with Venetoclax consistently developed excellent mixed chimerism, which was significantly superior to those induced by 3 Gy TBI but without Venetoclax (Fig. 2). Three combined KTx recipients also achieved renal allograft tolerance (>313, >946 and >1274 days).

Conclusions: Bcl-2 appeared to be a critical survival factor for HSCs and its inhibition resulted in promotion of chimerism induction with significantly lower dose of myelosuppressive treatment.

Abstract# 575

Donor Lymphocytes in Peripheral Blood of Patients After Lung Transplantation Comprise High Frequencies of Killer Cell Immunoglobulin-like Receptor-positive T and NK Cell Subsets

J. F. Kühne[1], A. Hitz[1], K. A. Bläsing[1], B. Wiegmann[2], R. Bellmàs Sanz[1], F. Ius[2], A. Haverich[2], G. Warnecke[2], C. S. Falk[1], *[1]MHH, Institute of Transplant Immunology, Hannover, Germany, [2]MHH, Department for Cardiothoracic, Transplantation and Vascular Surgery, Hannover, Germany*

Purpose: For end-stage lung diseases, lung transplantation (LuTx) is the only curative treatment option. However, acute and chronic rejections are major limitations. Thus, a deeper understanding of the contribution of immune responses early after LuTx is urgently needed. Passenger leukocytes, derived from donor lungs and migrating into the recipients` periphery, are primarily NK and T cells. Our aim was to characterize the expression of killer cell immunoglobulin-like receptors (KIR), regulating NK and $CD8^+$ T cell activity, on donor and recipient NK and T cells in recipient blood after LuTx. Moreover, we investigated the functional capacity of donor vs. recipient NK cells.

Methods: Peripheral blood samples at pre, T0hr, T24hrs and 3wks post Tx of n=51 LuTx recipients were analyzed for the presence of HLA-mismatched donor cells and their KIR repertoire as well as activation status using flow cytometry. These results were correlated with clinical parameters, i.e. primary graft dysfunction (PGD) and cold ischemic times (CIT).

Results: Within the first 3wks after LuTx, donor NK and T cells were detected in n=51 patients with a peak at T0hr. An increase of the KIR2DL1-positive subset was detected within the donor NK cell repertoire. Moreover, donor NK cells showed significantly higher frequencies of KIR2DL1-positive cells ($p<0.01$) 3wks post LuTx compared to recipient NK cells. This effect was also observed in donor T cells 3wks after LuTx with higher proportions of KIR2DL1- ($p<0.05$) and KIR3DL1- ($p<0.01$) positive T cells. Higher activation levels of donor NK and T cells ($p<0.001$) were detected as compared to recipient cells via CD25 expression as well as enhanced degranulation capacity upon activation by K562 target cells. The KIR repertoire on donor NK and T cells in LuTx recipient blood does not correlate with PGD, while the frequencies of KIR^+ donor NK cells increased directly after LuTx with longer CIT.

Conclusions: Higher frequencies of donor NK and T cells expressing KIR compared to recipient NK and T cells argue for their origin in the lung as part of a highly specialized immunocompetent compartment. Despite KIR expression, the activation level of donor NK and T cells in the periphery of the recipient may be higher compared to recipient cells. Moreover, a positive correlation was detected for KIR surface expression on NK cells and CIT but not PGD implying extended preservation times have an impact on the NK subset composition. Hence, donor NK and T cells might have a regulatory effect in the balance between tolerance and rejection as well as graft survival after LuTx.

Abstract# 576

Selective Bcl-2 Inhibition for Induction of Mixed Chimerism and Renal Allograft Tolerance without Myelosupression

G. Lassiter[1], T. Hirose[1], H. Sasaki[1], D. Ma[1], T. Oura[1], A. Dehnadi[1], A. Cosimi[1], P. Cippa[2], T. Fehr[3], T. Kawai[1], *[1]Center for Transplantation Sciences, Massachusetts General Hospital, Boston, MA, [2]Division of Nephrology, Ente Ospedaliero Cantonale, Lugano, Switzerland, [3]Division of Nephrology, University of Zurich, Zurich, Switzerland*

Purpose: Immunologic tolerance of renal allograft has been achieved by induction of hematopoietic chimerism through donor bone marrow transplantation (DBMT). The myeloablative and genetic toxicity associated with DBMT conditioning hampers widespread application of tolerance protocols. To this end, we have recently shown that the addition of selective BCL-2 inhibition with Venetoclax (Vtx) to our nonmyeloablative conditioning regimen can promote chimerism and allograft tolerance without myelosuppression. To establish the Vtx-based regimen for clinical application, the necessity of all aspects of the protocol for combined kidney and bone marrow transplantation was evaluated individually.

Methods: Cynomolgus monkeys received various regimens which included low dose total body irradiation (TBI), local TI and ATG pre-CKBMT, followed by a short course of anti-CD154 mAb and Cyclosporine. The study groups consisted of 6 arms. Group A and B received no Vtx, but 3GyTBI and 1.5Gy TBI. Groups C,D,E and F all received Vtx but 1.5Gy TBI, no TBI, no TI, or no CoB, respectively.

Results: All recipients of the conventional regimen, Group A, achieved chimerism and long-term allograft tolerance but experienced severe transient pancytopenia. With reduced TBI (1.5Gy) without Vtx, all recipients failed to develop chimerism and ¾ rejected by day 167. By adding Vtx, all three recipients achieved excellent

chimerism (Fig. 1) and renal allograft tolerance without pancytopenia. Without TBI or CoB, all recipients failed to develop chimerism and rejected kidney allografts. Without TI, all three recipients failed to achieve tolerance despite successful development of chimerism. In this group, early repopulation of recent thymic emigrants and naive T cells were observed.

Conclusions: TBI dose was reduced by adding Vtx, leading to successful chimerism and allograft tolerance without myelosuppression. Minimal TBI, TI, and CoB appeared to be essential in the protocol with selective Bcl-2 inhibition.

Figure 1

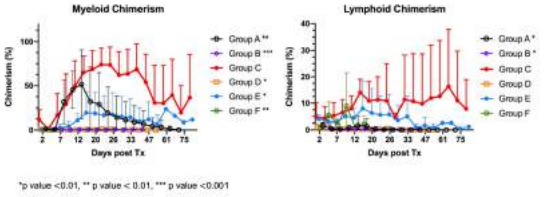

Table 1 Results of other factors in the regimen with Bcl-2 inhibition

	Group	n	TBI	TI	CoB	Vtx	Chimerism	Renal Allograft Survival (days)
No Vtx	A	8	3Gy	7Gy	+	-	7/8	2498, 4328, 837, 755, 401 373, 206, 58
	B	4	1.5Gy	7Gy	+	-	0/4	>688, 167, 100, 58
Vtx	C	3	1.5Gy	7Gy	+	+	3/3	>1276, >940, >326
	D	2	-	7Gy	+	+	0/2	120, 142
	E	3	1.5Gy	-	+	+	3/3	97, 100, 163
	F	3	1.5Gy	7Gy	-	+	0/3	74, 127, >66

TBI: total body irradiation, TI: thymic irradiation, CoB: costimulatory blockade using anti-CD154 mAb

Abstract# 577

Effects of IL-2 and/ or Anti-IL6R Therapy on Long-term Cardiac Allograft Survival in Non-Human Primates (NHPs)

C. L. Miller, K. J. Ahrens, J. M. O, P. M. Patel, J. A. Morrissette, D. Becerra, T. Costa, A. Dehnadi, I. M. Hanekamp, G. Benichou, J. C. Madsen, *Center for Transplantation Sciences, Massachusetts General Hospital, Boston, MA*

Purpose: Cardiac allograft tolerance in NHPs has been achieved by our group using a mixed chimerism model with allogeneic bone marrow transplant after non-myeloablative conditioning but not without kidney co-transplantation. Transplantation of the heart alone results in graft rejection within 150-180 days. Our results suggest that the ability of the kidney to confer tolerance on the co-transplanted heart relates to its ability to induce the expansion/activation of host regulatory T cells (Tregs). We investigated whether IL-2 and/ or anti-IL6R therapy could substitute for the kidney and induce cardiac allograft tolerance by augmenting Tregs.

Methods: Sixteen cynomolgus NHPs underwent heart and donor bone marrow transplant with mixed chimerism conditioning including total body and thymic irradiation, ATGAM, anti-CD154 mAb, and cyclosporine until post-operative day (POD) 28. Recipients in Group A (n=5) received low dose IL-2 therapy (1M IU/m^2 SC, POD -6 to 5) and an anti-IL6R mAb (tocilizumab, 10 mg/kg IV, POD 0, 7, 14, 21, 28, 56, 84, 112). Recipients in Group B (n=11) received tocilizumab alone (10 mg/kg IV, POD 0, 7, 14, 21, 28, 56, 84).

Results: In Group A, 3/5 recipients rejected at POD 127, 198, and 254 with acute cellular rejection (ACR), antibody mediated rejection (AMR), and donor specific antibodies (DSA). 2/5 died due to sepsis (POD11) or technical complications (POD7). In Group B, 4/11 recipients are ongoing, of which 2 are >430 days post-transplant without ACR. 1/11 rejected at POD 621 but only after donor skin transplant on POD 526. 1/11 failed to develop chimerism and rejected at POD 169. Graft failure/ death occurred in 5/11 due to technical or sedation complications (POD3, POD5 [n=2], POD9) and pancytopenia (POD65). Group A recipients exhibited an average 15-fold expansion in percent CD25+FoxP3+ of peripheral CD3+CD4+ cells compared to 3-fold expansion in Group B.

Conclusions: Despite its ability to promote Tregs, combined IL-2/ aIL6R treatment failed to achieve long-term allograft survival. We surmise that this was due to IL-2 stimulation of alloreactive memory T cells. In contrast, aIL6R mAb treatment alone achieved long-term allograft survival (>1 year) off immunosuppression in 3 recipients and represents a promising strategy towards clinical cardiac allograft tolerance.

Abstract# 578

Donor T and NK Cells with a Special Tissue-Resident Memory Phenotype Migrate Into the Periphery of Lung Transplant Recipients - A Potential Feature for Tolerance Development

L. M. Ruhl[1], R. Bellmàs Sanz[1], A. Hitz[1], B. Wiegmann[2], K. A. Bläsing[1], W. Sommer[2], F. Ius[2], J. F. Kühne[1], A. Knöfel[2], L. M. Horn[1], I. Tudorache[2], A. Haverich[2], D. Jonigk[3], G. Warnecke[2], C. S. Falk[1], *[1]MHH, Institute of Transplant Immunology, Hannover, Germany, [2]MHH, Department for Cardiothoracic, Transplantation and Vascular Surgery, Hannover, Germany, [3]MHH, Institute of Pathology, Hannover, Germany*

Purpose: After lung transplantation (LuTx), a transient chimerism of donor cells exists in the blood of recipients due to the migration of lymphocytes from the transplanted lung into the periphery. We aimed to characterize the phenotype of donor $CD8^+$ and $CD4^+$ T and NK cells and to investigate whether they might represent tissue-resident memory (TRM) cells.

Methods: Lymphocyte dynamics in recipient blood were determined in 97 lung transplant patients directly (T0), 24 hours (T24) and 3 (wks) weeks after LuTx using flow cytometry with lineage-, tissue-, and donor HLA class I allele-specific mAb. The same makers were used to determine the phenotype of lymphocytes present in organ storage solution (perfusate, n=102), recipient explanted lung parenchyma (n=28) and donor trachea (n=17).

Results: In peripheral blood of all recipients, donor-derived $CD4^+$ and $CD8^+$ T and $CD56^{dim}$ NK cells were detected at T0, T24 and 3 wks after LuTx and had higher CD69 expression compared to recipient cells ($p=0.01$ to 0.04), were mostly CCR7-memory cells and CD25 negative. This phenotype was similar to T and NK cells in corresponding perfusates. In recipient parenchyma and donor trachea, most $CD69^+$ T and NK cells showed coexpression of other tissue residency markers such as CD103, CD49a and PD-1 with significant enrichment in trachea ($p<0.05$). In contrast, these markers were not found in circulating donor lymphocytes and perfusates, indicating that they represent distinct memory T and NK subsets. Donor T and NK cells showed higher IFN-g production with and w/o PMA/Iono stimulation compared to recipient cells ($p<0.05$). The presence of these particular TRM cells did not have an impact on the development of PGD 24h after transplantation. However, patients with high frequencies of donor T cells showed a trend towards a CLAD-free survival 2 years post LuTx, although no statistical significance was reached ($p=0.15$).

Conclusions: Our results demonstrate that donor T and NK cells found in the periphery of lung transplant recipients are a distinct subset from circulating lymphocytes and TRM cells present in lung tissue, since they express CD69 but lack expression of other classical TRM markers. They display a higher functional capacity despite the onset of immunosuppression. Donor T cells might be clinically relevant for tolerance induction and long-term survival after transplantation due to their unique features.

Abstract# LB 39

Regulatory Macrophage Induced by Il-33 Promoted Immune Tolerance of Kidney Transplantation Through Siglec-10

J. d. zhang, w. wang, *Urology, Beijing Chaoyang Hospital, Capital Medical University, Beijing, China*

Purpose: Acute and chronic rejection are key problems in renal transplantation. It is ideal to induce immune tolerance to suppress rejection while regulatory macrophages (Mregs) which play critical roles are one of the approaches against rejection. Little do scientists know about how to further improve and establish the Mregs with powerful immunosuppressive function.

Methods: To solve this problem, we induced regulatory macrophages derived from BALB/c bone marrow through various cytokines in vitro. Cell phenotype was analyzed by flow cytometry. ConA stimulated T cell proliferation assay was used to evaluate Mregs inhibitory function. RNA-seq revealed immunosuppressive molecules that regulate the functioning of regulatory macrophages. RT-PCR and flow cytometry were used to further validate the identified immunosuppressive molecules.

Results: The results indicated that macrophages induced by IL-33 showed the characteristics of Mregs, which significantly inhibited the proliferation of T cells and promoted the high expression of Foxp3 in CD4+ T cells. Moreover, Mregs induced by IL-33 exert immunosuppressive function mainly through siglec-10.
Conclusions: Our study optimized the amplification system of Mregs induced by IL-33 in vitro and clarified systematically the characteristics of the gene expression profile of Mregs induced by IL-33 and the cellular and molecular mechanisms in the establishment of transplant immune tolerance. In summary, our study provides a strategy for the construction of immunosuppressive Mregs and comes up with a novel method to ameliorate rejection after renal transplantation.

Anti-HLA-DP Antibodies Positive - A Retrospective Review of Outcomes in Renal Transplantation- Single Centre Experience

O. Piscoran[1], J. Worthington[2], R. Dhillon[1], T. Augustine[1], M. Picton[1], M. Morton[1], S. Bhutani[1], *[1]Urology, Renal and Transplantation, Manchester University NHS Foundation Trust, Manchester, United Kingdom, [2]Transplantation Laboratory, Manchester University NHS Foundation Trust, Manchester, United Kingdom*

Purpose: Data on the role of HLA-DP antibodies on graft outcome is not precise. Studies suggested that the presence of donor-directed HLA-DP antibodies correlate with reduced allograft survival and increased ABMR risk among kidney transplant recipients. We investigated one -year graft outcomes of patients with donor-directed HLA-DP antibodies who received a renal transplant. Primary outcomes included dialysis independence at one-year and rejection (ABMR, TCMR or mixed).
Methods: Retrospective data were collected on 22 Kidney Transplant recipients who had donor-directed HLA-DP antibody at the time of transplantation
Results: We identified 22 patients. Induction IS: Basiliximab 6; Alemtuzumab 11; Unknown 5 Maintenance IS Myfortic, and Tacrolimus or Myfortic, Tacrolimus and Prednisolone.19 patients had deceased donor, and 3 patients had a live donor transplant. The majority of our patients were highly sensitised (cRF>85%) pre-transplant 81% (n=18). 18% (n=4) patients were not mismatched at HLA A, B, and DR. 68% were at their 2nd or 3rd transplant. At 1-year post-transplant, 68% (non-censored for death) had a working graft (defined as dialysis independent regardless of eGFR). Graft losses were due to rejection (1), surgical complication (1), unknown (2) and death with a functioning graft (4). A majority of 13 (59%) had DGF, and six patients had a biopsy in the first-week post-transplant (ATN- 5 and acute vascular rejection-1). 72%(n=16) had donor-directed HLA-DP antibody MFI > 5000 at the time of transplantation;63% (n=14) had a positive FCXM at the time of transplantation. Post tx only 10% had an increase in DP DSA MFI, 68% MFI remained the same or decreased, 23% became negative. 32% (n=7) had a biopsy-proven rejection. The majority 5 out of 7 being ABMR
Conclusions: Most of our patients were highly sensitised and at their 2nd or 3rd transplant. Even though 63% had positive FCXM at the time of transplantation, the rate of rejection was 32%. Most rejections were ABMR. At 1-year post-transplant, 68% of the patients were dialysis independent. Our centre experience suggests that KTx across DP DSAs with +/-ve FCXM could be a feasible option for carefully selected, highly sensitised patients who otherwise may not find a compatible donor.

Abstract# 580

Disparities in HLA Representation by Single Antigen Reagents in Different Ethnic Populations

J. C. Quon[1], J. Menteer[2], N. Fotiadis[2], R. M. Lestz[2], L. A. Baxter-Lowe[2], *[1]Keck School of Medicine of USC, Los Angeles, CA, [2]Children's Hospital Los Angeles, Los Angeles, CA*

Purpose: It is not possible to test for antibodies against the antigens encoded by every HLA allele due to cost and throughput constraints. When alleles are not represented in the single antigen reagents, donor specific antibodies may be missed because their antibody epitopes are not present. The extent of this problem is not evident without the benefit of allele-level typing, which is required to differentiate antigens in the panels and those expressed by donors. To investigate the limitations of single antigen reagents, HLA gene frequencies in four populations: European (EUR), African American (AFA), Asian/Pacific Islander (API), and Hispanic (HIS) were used to determine antigen coverage with single antigen reagents from two vendors.
Methods: Allele frequencies (Common, Intermediate, and Well Documented HLA allele catalog, version 3.0) were used to determine the percentage of HLA-A, -B, -C, and -DRB1 alleles for EUR, AFA, API, and HIS populations that are not represented in single antigen reagents. Three commercial products were compared: Vendor 1, Vendor 2, and a combination of three reagents (both vendors and a supplemental panel).
Results: For HLA-A, -B, -C, and -DRB1, the percentage of donor population unrepresented by the combined reagents ranged from 2.3% to 18.1% (Figure 1). The best representation was observed in the EUR population, where 6.3%, 8.4%, 17.5%, and 2.3% lacked representation at the HLA-A, -B, -C, and -DRB1 loci respectively. For the combined reagents, the percentage of each population not represented ranged from 7.1% to 14.6% for AFA, 3.4% to 18.1% for API, and 7.1% to 17.7% for the HIS population.

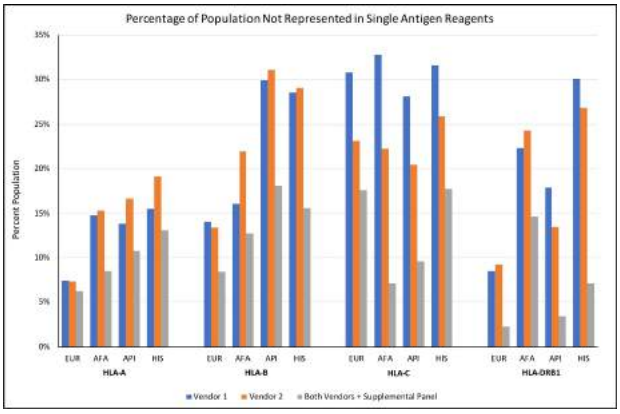

Figure 1. Percentage of EUR, AFA, API, and HIS populations that express HLA-A, -B, -C, and -DRB1 alleles not represented in single antigen reagents.
Conclusions: All populations have HLA antigens that are not represented in single antigen reagents, which could result in failure to detect clinically significant antibodies. Single antigen reagents better represent the antigens of the EUR population compared to those in AFA, API, and HIS populations. This suggests that allele-level typing is important to identify situations where donor specific antibodies may not be detectable, including prevention and treatment of antibody mediated rejection.

(Spain), Málaga, Spain*

Purpose: Subclinical inflammation (SCI) ($<t_2+i_2$ Banff Classification) is a very common histological finding in kidney transplants (KT) (± 40-60%) with modern immunosuppression. Its influence in reducing long-term graft survival is known. Our aim is to analyze whether HLA mismatching is associated with the risk of suffering from SCI.

Methods: As a part of clinical Trial NCT02284464, we collected the protocol biopsy results at third month after KT in 105 patients with low immunological risk. We evaluated the histological findings according to the Banff 17 classification. We divided them in Group I (n=51), with no inflammation (NI) and Group II (n=54) with SCI. We analyzed the HLA-histocompatibility between donor and recipient with PCR-SSP. We determined A, B, C, DR and DQ alleles.

Results: Most of the patients were male and the donor mean age was 52 years old in Group I and 55 in Group II. There were no differences in the time in dialysis, cold ischemia time, induction therapy, tacrolimus levels, pretransplant PRA or the delayed graft function (DGF). We found that those who had SCI had a worse graft function and more chronic lesions than the NI group (ct+ci+cg+cv 1.6±1.2 vs 0.76±1.03 p=0.001). Group II had more HLA mismatching than Group I.62.5% of the patients who presented with NI had less than or equal to 6 HLA-incompatibilities. 61.5% of those with SCI had more than 6 HLA-incompatibilities.$$table1

	NI (n=51)	SCI (n=54)	p
Donor age (years)	52.4±13.4	55±11.8	0.311
Expanded criteria donor (%)	36	49,1	0,181
Recipient BMI (kg/m²)	27.4±3.9	25.7±4.3	0.094
Male (%)	72.5	74.1	0.860
Hemodialysis (%)	72	64,8	0.686
Time in dialysis (months)	24.3±17.5	19.3±1.1	0.182
Induction therapy (%)	53.9	90.2	0.270
Cold ischemia time (h)	10.6±6.7	10.8±6	0.877
Pretransplant PRA (%)	0,43±2.7	0	0.323
DGF (%)	24	26.9	0.735
Tacrolimus levels (ng/ml)	9.7±2.9	9.2±2.1	0.286
HLA mismatches (n) (A,B,C,DR,DQ)	5.4±2.4	6.9±2	0.002
Proteinuria (mg/dl)	297.4±229.4	278.9±224.9	0.763
MDRD-4 (ml/min)	60±23.4	48.5±13.6	0.003

Conclusions: We highlight the importance of HLA mismatching in patients with low immunological risk and the assessment in the induction therapy as well as in the maintenance immunosuppression.

Abstract# 582

The Co-Occurrence of Newly Developed HLA Donor Specific Antibody and Positive C3d/C4d Profiles Along with Immune Therapy Non-Compliance in Pediatric Heart Transplant Recipients is a High Risk Indicator for Patient Mortality

A. Zhang, C. Nasman, J. Allen, Y. Sun, D. Thomas, R. Rodriguez, C. Tan, G. Boyle, *Cleveland Clinic Foundation Transplant Center, Cleveland, OH*

Purpose: Increasing evidence has implicated the deleterious effect of HLA donor specific antibody (DSA) in pediatric heart transplantation (PHTx). However, there are still insufficient research results illustrating the comprehensive predictors that lead to severe graft failure and mortality. This study sought to investigate the degree to which DSA has contributed to negative PHTx outcomes in correlation with other potential detrimental factors.

Methods: A total of 155 recipients (164 allografts) who underwent PHTx between 1985-2019 were retrospectively analyzed for DSA (Mean Fluorescent Intensity ≥1000 as positive, ≥4000 as strong, ≥17,000 correlated to +C1q as high risk), C3d and C4d, and demographic characteristics (Table 1b). Antibody mediated rejection (AMR), graft failure (GF), and patient expiration (PE) were evaluated as PHTx outcomes. *P* values were calculated by chi-square or Fisher exact tests for categorical variables and by Wilcoxon rank test for continuous varibles.

Results: Newly developed DSA (ndDSA) was significantly related to the occurrence of AMR ($p<0.05$ and $p<0.001$) and PE (all $p<0.05$), but not to GF. Preformed DSA had no apparent negative effect on PHTx outcomes (Table 1a). Non-compliance with immune therapy (NC) was significantly associated with AMR, GF and PE (all $p<0.05$). Median ages of NC vs compliance were 14 (13-18) and 7 (2-14), respectively. Assist devices were correlated with low occurrences of GF and PE (all $p<0.05$). No other demographic characteristic included in this study displayed an impact on PHTx (Table 1b). High risk and strong DQ ndDSA with positive C3d/C4d showed significant correlation to GF and PE (all $p<0.05$). Interestingly, the combination of strong DQ ndDSA, positive C3d/C4d, and the additional risk factor of NC demonstrated a dramatic increase in the incidence of PE ($p<0.001$) (Table 1c).

Conclusions: High risk and strong DQ ndDSA supported by pathological findings is a critical barrier of successful PHTx for teenaged recipients with immune therapy compliance issues. The co-occurrence of these factors warrant timely enhanced post PHTx management to prevent final allograft failure and patient mortality.

Immunosuppression Preclinical Studies

Abstract# 583

Transforming Growth Factor-Beta Induced Myeloid-Derived Suppressor Cells Promote Transplant Immune Tolerance

F. Zhang, *Department of Urology, Beijing Chaoyang Hospital, Capital Medical University, Beijing, China, Beijing, China*

Purpose: Myeloid-derived suppressor cells (MDSCs) are a group of heterogeneous cells derived from bone marrow with immunosuppressive effect, which contribute to the establishment of transplant immune tolerance. Obtaining a sufficient number of MDSCs with potent suppressive function and good stability is a prerequisite for their clinical transformation and application. Our research found that transforming growth factor-beta (TGF-b) induced MDSCs with potent suppressive function promoted transplant immune tolerance.

Methods: In vitro, we used mouse bone marrow cells as precursor cells for the induction of MDSCs, which obtained by TGF-b combined with GM-CSF, a growth factor stimulating the proliferation and differentiation of bone marrow cells. Flow cytometry detected the phenotype of induced MDSCs, and the immunosuppressive function and underlying cellular and molecular mechanism of these cells were explored by mixed lymphocyte culture and mouse skin transplantation model.

Results: Compared with GM-CSF treatment alone, TGF-b combined with GM-CSF could induce more MDSCs, which have a stronger function of inhibiting activated $CD4^+$ and $CD8^+$ T cells. In addition, TGF-b induced MDSCs expressed higher levels of PD-L1. We further found that TGF-b induced MDSCs promoted the production of Tregs, and upregulated the expression of a variety of immunosuppressive molecules. Finally, adoptive transfer of these cells significantly prolonged the survival of allograft and promoted transplant immune tolerance.

Conclusions: These results indicated that TGF-b combined with GM-CSF is an efficient and stable protocol to induce MDSCs *in vitro*. TGF-b induced MDSCs play a stronger immunosuppressive effect though inducing the production of Tregs and the expression of immune effector molecules. We firmly believe that TGF-b induced MDSCs combined with immunosuppressants are promising to further prolong the survival of allograft and promote transplant immune tolerance.

Islet Cell and Cell Transplantation

Abstract# 584

Islet Isograft Transplantation Improves Insulin Sensitivity in a Murine Model of Type 2 Diabetes

S. Lim, M. Choi, M. Kim, Y. Wee, H. Kwon, C. Jung, Y. Kim, D. Han, S. Shin, *Asan Medical Center, Seoul, Songpa, Korea, Republic of*

Purpose: Type 2 diabetes develops in the presence of chronic overnutrition and genetic susceptibility, and causes insulin resistance and relative insulin deficiency. We hypothesized that islet transplantation can improve insulin sensitivity by modifying the mediators of insulin sensitivity in the pancreas, liver, muscle, adipose tissues.

Methods: Eight-weeks-old male mice were used as both recipients and donors in this study. To induce type 2 diabetes with partial β-cell failure, the mice were fed a high-fat diet for 4 weeks and then injected with low-dose streptozotocin. Approximately 400 islet cells from a donor mouse were injected into the renal capsule of a recipient mouse for islet transplantation. After six weeks following transplantation, the mediators of insulin sensitivity in the pancreas, liver, muscle, and adipose tissues were quantitatively compared between islet-transplanted and non-transplanted groups.

Results: Intravenous glucose tolerance test showed that whereas the non-transplanted mice failed to show notable reductions in the glucose level, the islet-transplanted mice showed significant reductions in the serum glucose level to ~200 mg/dL at six weeks after islet transplantation. The islet-transplanted mice showed significantly higher Matsuda index and significantly lower HOMA-IR than did the non-transplanted mice, thus signifying improved insulin sensitivity. In the kidney, the insulin/amyloid ratio significantly increased between three and six weeks after islet transplantation. In the liver, the expression levels of insulin sensitivity mediators (ie, adiponectin, GLUT2, IRS-1, and pIRS-1) were significantly higher in the islet-transplanted mice. The islet-transplanted mice also had significantly higher expression levels of IRS-1 in white adipose tissues and GLUT4 in brown adipose tissues compared with non-transplanted mice. Lastly, the islet-transplanted mice showed a significant increase in adiponectin and a decrease in interferon-gamma in white muscle tissues; moreover, the islet-transplanted mice had a significantly higher ratio of phosphorylated AMP-activated protein kinase-α/AMP-activated protein kinase-α in red muscle tissues compared with the non-transplanted mice.

Conclusions: Islet transplantation resulted in improvements in multiple indices of insulin sensitivity in a murine model of type 2 diabetes. Islet transplantation may be utilized to improve insulin sensitivity in patients with type 2 diabetes.

Abstract# 585

Lacripep™-like Peptide N-104 Increases Insulin Secretion and Promotes Islet Transplantation Outcomes

M. Ma, P. Chhabra, K. Dias Teixeira, G. Laurie, K. Brayman, *University of Virginia Health System, Charlottesville, VA*

Purpose: To study if Lacripep™-like peptide N-104 promotes beta-cell stabilization and islet transplantation outcomes. **Background:** Lacritin is a multifunctional tear protein with prosecretory, prosurvival and mitogenic properties. Islets are Lacritin responsive, and prominently express known elements of the Lacripep™ receptor complex and signaling pathways. N-104 peptide comprises the fifteen C-terminal amino acids of Lacritin.

Methods: a) Human or mouse islets were cultured with 4μM of Lacripep™-like peptides N-94, N-104, N-104/C-6 or Tearpep3/N-104, or with negative control C95 or were left untreated in DMEM at 37oC for different periods of time ranging from 1 - 20 days. Islet viability was scored by propidium iodide - fluorescein diacetate staining, and function by Glucose Stimulated Insulin secretion (GSIS) assay. b) C57BL/6 islets were pretreated with 4 μM N-94, N-104, or C95, or saline for 24 hours followed by minimal islet mass transplantation into syngeneic diabetic recipients. Tail vein blood glucoses were measured daily.

Results: For mouse islets, N-104 was ~45% more active than N-94 and 25% better than TearPep3/C-6 in GSIS assays. N-104 increased GSIS by about 5.5-fold, while N-94 or Tearpep3/N-104 increased GSIS by about 4-fold compared to untreated controls. Human islets cultured for 24hrs in the presence of N-104 also demonstrated a 2.7-fold GSIS increase compared with untreated controls. N-104/C-6 (in which six C-terminal amino acids have been removed) failed to enhance GSIS compared to untreated islets. The viability of human islets treated with N-104 was 95.6% at Day 6, and 84%, 66% and 58% following culture with N-94 C-95, and saline. Incubation of mouse islets with N-104 permanently returned syngeneically transplanted mice to normoglycemia with glucoses below 200mg/dL within 7 days post-transplant, with treatment efficacy continuing 55 days post-transplant. In comparison, N-94 restored blood glucose levels to normal after 9 days post-transplant. Blood glucose was <250mg/dL following treatment with C95 at Day12 post-transplant. Average blood glucoses measured between Days 22 to 43 was 151±20.7mg/dL for N-104 group and 142.9±17.6mg/dL for N-94 group compared to 275±34.8mg/dL for the C95 group.

Conclusions: Islet viability, glucose stimulated insulin secretion, and transplantation outcomes indicate that N-104 is the most viable candidate for clinical translation as an interventional agent to promote islet transplantation outcomes.

Abstract# 586

A Small Molecule Inhibitor of Toll-like Receptor-4 TAK-242 Attenuates IBMIR Against Human Islets

J. Mattke[1], S. Vasu[1], K. Kumano[1], Y. Liu[1], C. M. Darden[1], M. C. Lawrence[1], R. R. Kane[2], B. Naziruddin[1], *[1]Baylor University Medical Ctr, Dallas, TX, [2]Baylor University, Waco, TX*

Purpose: A large portion of grafted islets are lost shortly after infusion due to the instant blood mediated inflammatory reaction (IBMIR). In our previous studies, we have observed increased viability and functionality of transplanted islets as well as decreased inflammatory markers in serum when islets were transplanted into mice following isolation with TAK-242 supplemented solutions. Therefore, we sought to investigate the effects of TAK-242 in an in vitro IBMIR model using human islets.

Methods: Following isolation of human islets, islets were allowed to recover in culture for 24 hours. Islets were challenged with the administration of whole blood with and without supplemental TAK-242. Serum or supernatant was collected at 0 and 3 hours. These samples were analyzed for damage associated biomarkers hsa-miRNA 375 using RT-qPCR. C-peptide was measured by ELISA. IL-1β, IL-6, and IL-8 in plasma or supernatant were measured by Luminex assay.

Results: Damage associated hsa-miRNA 375 showed a significant decrease ($p<0.005$) with the addition of TAK-242 when compared to control after being exposed to blood for 3 hours (Figure 1). C-peptide also showed decreases in TAK-242 samples ($p<0.005$) following 3 hours of exposure to whole blood further verifying attenuated islet stress and damage with the administration of TAK-242. Inflammatory cytokines IL-1β, IL-6, and IL-8 in TAK-242 treated samples also showed significant decreases compared to control ($p<0.05$) after 3 hours exposure to blood.

Conclusions: The results of this study confirm the efficacy of TAK-242 and its ability to attenuate IBMIR in a human in vitro model as all markers measured in this experiment showed decreases in damage and inflammatory biomarkers of islets. This study also implicates the TLR4 signaling pathway as a potential therapeutic target for attenuating IBMIR during islet transplant procedures.

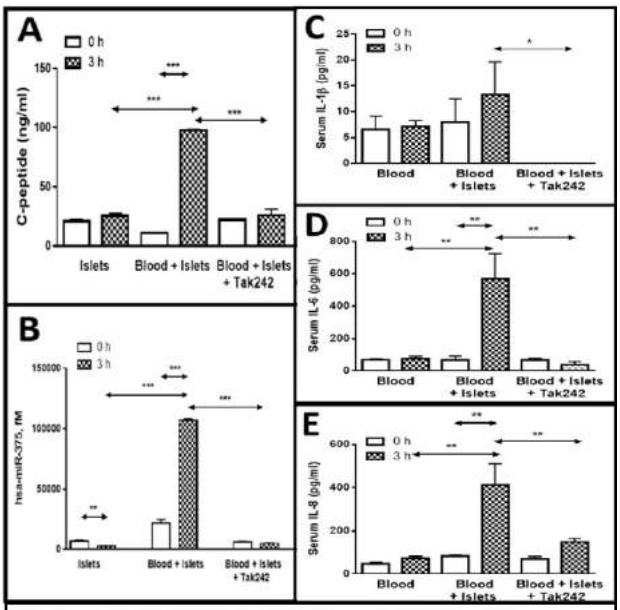

Figure 1. Measurement of damage and inflammatory markers with or without TAK242. A. C-peptide levels 0h and 3h following challenge with blood. B. hsa-miRNA levels following addition of blood. C-E. Levels of inflammatory cytokines IL-1β, IL-6, IL-8 following treatment of islets with blood. ***p<0.005, **p<0.05

Abstract# 587

Bone Marrow-Derived Mesenchymal Stem Cells Improve Rat Islet Graft Revascularization by Upregulating Isl1

W. Ying, J. Wang, X. Ding, *Kidney Transplantation, The First Affiliated Hospital of Xi'an Jiaotong University, Xi An, China*

Purpose: Revascularization of the transplant islet is a crucial step that defines the success rate of patient recovery. Though bone marrow-derived mesenchymal stem cells (BMSCs) have been reported to promote revascularization, its cellular mechanism remains unclear. The transcription factor, insulin gene enhancer binding protein-1 (ISL1), which is involved in islet cell proliferation also plays a potential regulatory role in the revascularization of islet cells. Our LC−MS/MS analyses results showed that BMSCs could promote the expression of ISL1 in islets. Hence, we set out to investigate the potential role of ISL1 in the revascularization process of islet transplantation.

Methods: Pancreatic islets and BMSC were isolated from Lewis rats. Quantitative proteomic analysis with TMT labeling was conducted to evaluate the change of protein profiles between islets that were cultured with or without BMSCs. By using in vitro co-culturing system and rat diabetes model, we examined the function, revascularization and ISL1 expression in islets and in rat pancreatic β (INS-1) cells with or without co-cultured/co-transplanted with BMSCs. Furthermore, INS-1 cells were transfected with lentivirus that can elevate or inhibit ISL1 expression. Chromatin immunoprecipitation (ChIP) were used to investigate the potential correlation between ISL1 and vascular endothelial growth factor A (VEGFA).

Results: Our LC−MS/MS data showed that the expression of ISL1 and VEGFA were significantly increased in the islets after it was co-cultured with BMSCs. The results from in vitro co-culturing system and rat diabetes model showed that the survival rate and insulin secretion from islets were increased with BMSCs were present, indicating that BMSCs promotes islet revascularization. We also observed that the presence of BMSCs led to an increase of ISL1 and VEGFA expression in both the islets and INS-1 cells. In silico protein structure modelling indicate that ISL1 is a transcription factor that has 4 binding sites with the mRNA of VEGFA. Further results showed that over-expression of ISL1 increased both the abundance of VEGFA transcripts and protein accumulation, whilst inhibition of ISL1 decreased the abundance of VEGFA. CHIP-qPCR assay results indicated that direct molecular interactions between ISL1 and VEGFA occur in INS-1 cells.

Conclusions: Our results revealed that BMSCs promote the expression of ISL1 in islets and lead to an increase of VEGFA in grafted islets. Hence ISL1 is a potential target to induce early revascularization for islet transplantation.

Abstract# 588

Cold Perfusion for Ischemia Minimization Reduces Cardiac Injury in an Ex Vivo Xenoperfusion Model

M. R. Connolly[1], A. Calhoun[1], F. Pollok[1], L. Burdorf[1], Z. Habibabady[1], M. Ma[1], S. Miura[1], W. Eyestone[2], C. Phelps[2], D. Ayares[2], *[1]Massachusetts General Hospital, Boston, MA, [2]Revivicor, Blacksburg, VA*

Purpose: Prior studies using Steen's cold perfusion storage technique for heart ischemia minimization (IM) prevented initial xenograft dysfunction (IXD). Our pilot data evaluates the effect of IM on cardiac injury and function during subsequent *ex vivo* xenoperfusion of wild-type (WT) and quadruple knock-out (QKO) porcine hearts.

Methods: Hearts from pigs with knockout of growth hormone receptor and the three principal antigens causing antibody-mediated graft injury (QKO) were compared to WT hearts on an *ex vivo* perfusion circuit. Three QKO and 1 WT hearts were perfused with a cold Steen solution for 2.5h after procurement (IM); 2 QKO and 2 WT hearts were cold-stored in iced saline for 2.5h (CS). Cardiac function was assessed in working heart mode (WHM) during subsequent perfusion with fresh human blood.

Results: Both WT CS hearts did not generate forward flow in WHM; 1 WT IM heart had declining function and failed at 3h (Fig.2F). Troponin levels increased throughout *ex vivo* perfusion in both QKO and WT groups, however troponin elaboration (as mean final troponin, ng/mL) was significantly attenuated with IM compared to CS for WT (IM 185, CS>1000; p=0.02) but not QKO hearts (IM 750, CS>1000; p=0.37)(Fig.1). Cardiac function (as increase in cardiac output with increased LA pressure) was relatively preserved over 4h in 2/3 QKO IM hearts (Fig2A,B) and 1/2 QKO CS hearts (2E), while 3/3 WT hearts (2 with CS; 1 with IM, 2F) and 2/5 QKO hearts (1 with IM, 2C; 1 with CS, 2D) failed within 4h. In this pilot series, IM did not significantly improve survival to 4h.

Conclusions: IM with cold Steen solution appears to protect WT hearts from IXD, with a trend toward reduced cardiac injury (as troponin release) during subsequent perfusion with human blood for both WT and QKO hearts. While preliminary, these observations support prior demonstrations of the effectiveness of IM to prevent IXD

in orthotopic cardiac xenotransplantation. The incomplete physiologic protection and residual troponin release seen in QKO hearts despite IM indicates the need to address other mechanisms of graft injury such as complement, coagulation, and adhesive interactions.

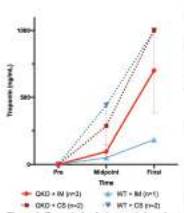

Figure 1. Troponin levels increased throughout all experiments over time, with cold perfusion (solid lines) trending toward delayed and attenuated rise compared to the non-cold perfused hearts (dotted lines) for both TKO:GhKO (red) and WT (blue) groups.

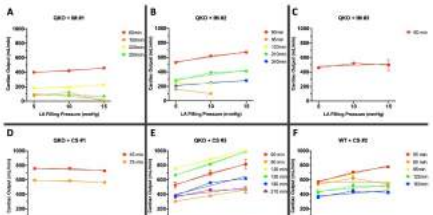

Figure 2. Cardiac performance under loading conditions trended toward more rapid decline during xenoperfusion in the hearts preconditioned with cold saline (CS) (D-F) than those with ischemia minimization (IM) preconditioning (A-C), as demonstrated by flattening of the cardiac output curve with increasing left atrial filling pressure over time.

Abstract# 589

Imaging Flow Cytometry Reveals That Platelet-Sized Erythrocyte Fragments are Formed During Pig Organ Perfusion with Human Blood

Z. A. Habibabady[1], F. Ellett[2], L. Burdorf[1], M. Connolly[1], F. Pollok[1], D. Irimia[2], R. N. Pierson III[1], A. M. Azimzadeh[1], *[1]Center for Transplantation Sciences, Massachusetts General Hospital and Harvard School of Medicine, Boston, MA, [2]Center for Engineering in Medicine and Surgery, Massachusetts General Hospital and Harvard School of Medicine, Boston, MA*

Purpose: Severe thrombocytopenia frequently occurs after xenotransplantation of porcine cells or organs, and when pig organs are perfused with human blood. We developed a flow cytometry-based technique to accurately quantify platelets and to distinguish them from similarly-sized particles found in blood during cross-species organ perfusion studies.

Methods: Three pairs (n=6) of wild type pig lungs were perfused with heparinized human whole blood. Blood perfusate was left untreated (n=3) or treated with a thromboxane synthase inhibitor and histamine receptor blocker (n=3). Platelet counts measured by an Heska (Hematru) traditional hemocytometer (HC), and a refined flow cytometric method (FC) using calibrated beads. FC results analyzed by FlowJo were compared with HC results. Imaging flow cytometry using Image StreamX Mark II imaging flow cytometry (Amnis Corporation) was employed to visualize and identify blood elements.

Results: Platelet counts measured by FC showed a decreasing trend over time while platelet counts by HC showed an increasing trend and large variations within 4hrs of lung perfusion (Figure 1). FC analysis revealed an increasing population of "platelet-sized events" which were negative for human platelet markers (CD41, CD61). Using human leukocyte (CD45), erythrocyte (CD235a), and pig-specific (CD41, CD45, CD31) antibodies a majority of platelet-sized CD41-negative events express the CD235a red blood cell marker (Figure 2A). Platelets, intact RBC and platelet-sized RBC fragments were distinguishable by AMNIS (Figure 2B).

Conclusions: Flow cytometric counting improves the accuracy of platelet enumeration. AMNIS image analysis reveals that red blood cell fragments are falsely detected as platelets by hemocytometers, causing overestimation of platelet counts by that method.

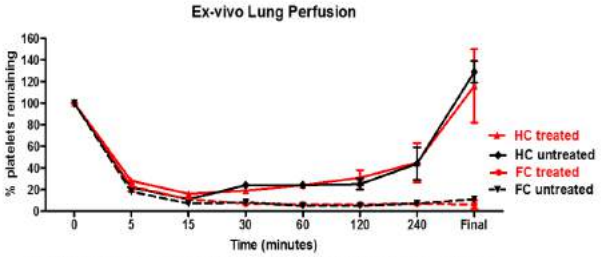

Figure 1. Comparison of platelet counts (mean ± SEM) from flowcytometry vs. hemocytometers in ex-vivo lung perfusions.

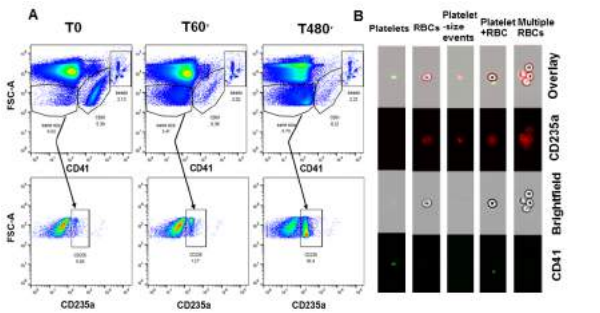

Figure 2. A) Platelet numbers (CD41+ events) decrease overtime, while platelet-like events(CD41-) increase, the majority of platelet-like events express CD235a. **B)** Platelets, intact RBC and platelet-sized RBC fragments visualization by AMNIS

Abstract# 590

Initial Experience with Growth Hormone Receptor Knockout in Pig-to-Baboon Kidney Transplantation: Effect on Ureteric Viability and Kidney Growth

C. Hansen-Estruch[1], H. Iwase[1], A. Jagdale[1], T. Yamamoto[1], M. H. Bikhet[1], J. Foote[2], H. Hara[1], D. Anderson[1], P. Porrett[1], D. Eckhoff[1], D. Ayares[3], W. Eyestone[3], J. Locke[1], D. K. Cooper[1], *[1]Xenotransplantation Program, Department of Surgery, University of Alabama at Birmingham, Birmingham, AL, [2]Department of Microbiology and Animal Resources Program, University of Alabama at Birmingham, Birmingham, AL, [3]Revivicor, Blacksburg, VA*

Purpose: The purpose of this study was to report outcomes of pig-to-baboon renal transplants using a novel growth hormone receptor knockout (GHRKO) organ-source pig created to address rapid initial kidney graft growth seen in prior xenotransplant experiments.

Methods: Kidney transplants from pigs expressing the GHRKO modification were carried out in 13 baboons. The immunosuppressive regimen included induction therapy with ATG (Thymoglobulin), anti-CD20mAb (Rituximab), and cobra venom factor or a C1-esterase inhibitor, and maintenance therapy based on anti-CD40mAb, rapamycin, and low-dose steroids. In Group A (n=7), a standard surgical procedure was carried out, as previously described, including bilateral native nephrectomy and graft implantation to the aorta and inferior vena cava. In Group B (n=6), much greater peri-ureteral tissue was maintained with the graft.

Results: Five of the first 7 baboons (71%) (Group A) developed a urinary leak between 8 and 25 days post-transplant from necrosis of the distal pig ureter, a complication we have never seen previously. In one case, the entire ureter had necrosed. In 2 of the 5 cases, histopathological features of antibody-mediated rejection were present in the kidney and ureter. In Group B, modifications to the surgical technique to ensure retention of vascularity of the ureter, e.g., maintenance of peri-ureteric tissue, prevented a ureteric leak. Baboons from both groups with graft survival greater than 30 days demonstrated an approximate 40% reduced graft growth compared with historic controls as measured by kidney dimensions seen on ultrasound.

Conclusions: Grafts from GHRKO pigs have reduced growth post-transplant compared to historical controls. GHRKO may have a detrimental effect on healing of the anastomosis between the graft ureter and recipient bladder, but does not affect healing of the vascular anastomoses or the abdominal wound. Taking special steps to maintain ureteric vascularity can prevent this problem.

Abstract# 591

Anti-pig IgE and IgA Antibodies in Sera of (i) Naïve Primates and (ii) Non-human Primates Sensitized to Pig Xenografts

H. Hara, Q. Li, H. Iwase, T. Yamamoto, D. Ayares, D. K. Cooper, *University of Alabama at Birmingham, Birmingham, AL*

Purpose: Anti-pig IgM and IgG antibodies in primates play an important role in xenograft rejection. The possible roles of anti-pig IgE and IgA have not been investigated. Our aim was to measure (i) preformed serum anti-pig IgE and IgA in naïve humans and nonhuman primates (NHPs), (ii) elicited IgE and IgA after pig organ or tissue transplantation in NHPs, and (iii) their deposition in rejected pig xenografts.

Methods: The binding of IgM, IgG, IgE and IgA antibodies to red blood cells (RBCs) from WT, GTKO, and TKO (i.e., not expressing Gal, Neu5Gc, or Sd^a xenoantigens) pigs was measured by flow cytometry in naïve humans (n=50) and baboons (n=14). Antibody binding to WT and GTKO pig (p) RBCs was also measured in the sera of baboons (non-sensitized: n=7, sensitized: n=2) and rhesus monkeys (non-sensitized: n=2, sensitized: n=11) following WT or GTKO pig organ/tissue xenotransplantation. Deposition of IgE/IgA in the grafts was detected by immunohistochemistry.

Results: The majority of humans had natural preformed IgM/IgG/IgE/IgA to WT and GTKO pRBCs. In contrast, IgM/IgG/IgE/IgA to TKO pRBCs were present at lower levels and frequency ($p<0.01$) (Figure 1A). Baboons also had IgM/IgG/IgE/IgA antibodies against WT pRBCs, but less to GTKO and TKO ($p<0.01$) (Figure 1B). After xenotransplantation into NHPs, when IgM/IgG increased, IgE/IgA also increased, but to a lesser extent. In addition to IgM/IgG, IgE and/or IgA deposition was observed in rejected pig xenografts.

Conclusions: Primates, especially humans, have natural IgE/IgA antibodies to GTKO pig cells, but little or none to TKO pig cells. After exposure to a pig graft, IgE and IgA antibody levels increase, but not to the same extent as IgM or IgG. Their exact role, if any, in xenograft rejection remains uncertain.

Abstract# 592

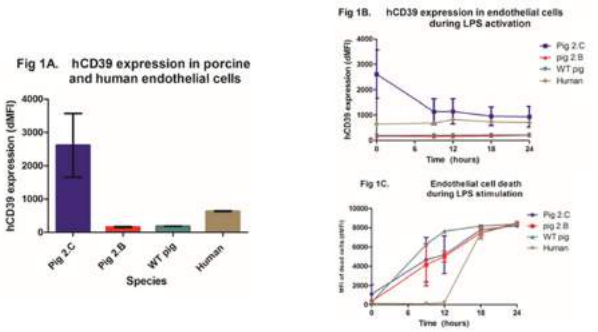
Transgenic Overexpression of Human Ectonucleoside Triphosphate Diphosphohydrolase 1 (entpd1, Or Hcd39) in Pig to Primate Xenotransplantation Models

R. Matheson[1], K. Deng[1], K. M. Lee[1], Z. A. Habibabady[1], C. G. Rickert[1], K. J. Ahrens[1], J. M. O[1], D. Becerra[1], P. Patel[1], W. Westlin[2], M. Youd[2], N. Serifis[1], T. M. Coe[1], D. Cloonan[1], A. M. Azimzadeh[1], C. LeGuern[1], J. C. Madsen[1], S. C. Robson[3], J. F. Markmann[1], *[1]Transplantation Surgery Research, Massachusetts General Hospital, Boston, MA, [2]eGenesis, Cambridge, MA, [3]Beth Israel Deaconess Medical Center, Boston, MA*

Purpose: Human CD39 (hCD39) is the gene of interest in xenotransplantation due to its reported capacity to prevent platelet aggregation by metabolizing extracellular ATP to AMP, reducing IL-6 and ALT and depleting resident $CD4^+$ T lymphocyte in the graft. One heterotopic cardiac xenotransplantation using a TKO-hCD39 donor (Pig 2.C, n=1) survived >100 days. We studied the impact of endothelial cell activation and expression of hCD39 on survival of aortic endothelial cells (AEC) recovered from normal and genetically modified pigs.

Methods: AECs from wild type (WT) (n=1), TKO.hCD39 (Pig 2.C; n=3), TKO (Pig 2.B; n=3) pigs and one human deceased donor were isolated and activated using LPS (1ug/mL), Ionomycin (1ug/mL), and PMA (50ng/mL) for 9, 12, 18 and 24 hours at 37°C. CD31 and hCD39 expression and viability were measured by flow cytometry.

Results: TKO.hCD39 AECs expressed more hCD39 than hAECs, while, as expected, no human CD39 was detected on WT or TKO AECs (Fig 1A). However, after nine hours of LPS challenge, hCD39 expression by the TKO.hCD39 AECs decreased to less than 50% of baseline, while expression of CD39 remained stable in the human AECs (Fig 1B). At nine hours, substantial cell death, as well as decreased CD39, was observed in the activated TKO.hCD39. At 18 hours, cell death measurements in the TKO.hCD39 AECs neared the maximal level observed at 24 hours. In the human AECs, no significant cell death was observed at 9 and 12 hours. However, at 18 hours the signal representing dead hAECs was high (Fig. 1C).



Conclusions: When compared to porcine AECs, human AECs appear more resistant to activation-mediated cell death. Overexpression of transgenic CD39 in the pig AEC did not afford significant protection, potentially as levels of hCD39 decreased with cellular activation. Further work will be conducted in order to understand effects of hCD39 and other human transgenes in these genetically engineered animals and to determine the impacts on immune and thromboregulatory pathways *in vivo*.

Abstract# 593

HTFPI.hCD47 and Adhesion Inhibition in GTKO.hCD46 Pig Lung Xenograft Injury

S. Miura[1], L. Burdorf[1], Z. Habibabady[1], A. Dandro[2], M. Connolly[1], S. Pratts[1], C. Phelps[2], W. Eyestone[2], D. Ayares[2], A. Azimzadeh[1], R. Pierson III[1], *[1]Center for Transplantation Sciences, Massachusetts General Hospital, Charlestown, MA, [2]Revivicor, Inc, Blacksburg, VA*

Purpose: We evaluate whether genetic expression of human tissue factor pathway inhibitor (TFPI, extrinsic coagulation pathway inhibitor) and human CD47 ("don't eat me" immunoregulator), alone or with combined PSGL-1 (selectin) and Mac-1 (integrin) ("adhesion inhibition"), influences GalTKO.hCD46 porcine lung injury during perfusion with human fresh blood.

Methods: Expression of TFPI and CD47 was confirmed by qRT-PCR and immunochemistry; TFPI function on pAECs was assessed using a thrombin generation assay. In a well-established paired *ex vivo* lung perfusion model, GTKO.hCD46.hTFPI.hCD47 transgenic pig lungs (n=5) were compared to reference GTKO.hCD46 lungs (n=5). All lungs were treated with a thromboxane synthase inhibitor (1-BIA), anti-histamine (Famotidine), and anti-GPIb integrin-blocking Fab. In both genotypes, one lung of each pair was additionally treated with adhesion inhibitors (n=4 hTFPI.hCD47, n=3 reference).

Results: *In vitro,* GTKO.CD46.TFPI.CD47 pAEC triggered less thrombin formation compared to GTKO (normalized AUC: 93 +/- 2 vs. 100 +/- 0.4, $p<0.005$). *Ex vivo*, all except for two GalTKO.hCD46 lungs (183, 440 min) survived until elective termination at 8 hours. Additional adhesion inhibition moderately lowered PVRs in lungs expressing hTFPI.hCD47 during the first 2 hours. Neutrophil sequestration was significantly delayed during the first hour ($P<0.05$) in association with hTFPI.hCD47 expression, but not with adhesion inhibition (Fig.A). Lungs expressing hTFPI.hCD47 significantly attenuated terminal platelet activation measured by CD62P expression compared to GTKO.CD46 ($P<0.001$) (Fig.B). Additional adhesion inhibitors didn't further suppress platelet activation in GalTKO.hCD46 or GalTKO.hCD46.hTFPI.hCD47-expressing lungs.

Conclusions: Expression of hTFPI.hCD47 showed protective effects (prolonged survival, delayed initial neutrophil sequestration and attenuated platelet activation) under these study conditions. While additional adhesion inhibitor reduced PVR elevation associated with hTFPI.hCD47 expression, it didn't significantly attenuate neutrophil or platelet sequestration by the lung. We conclude that non-canonical

adhesive mechanisms mediate the adhesion of human formed blood elements to pig endothelium that occurs even in the context of multiple genetic modifications and drug treatments designed to attenuate lung xenograft injury by these pathways.

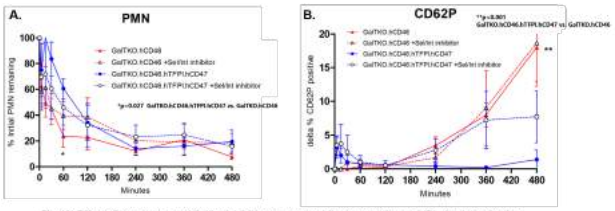

Fig. (A) Effect of transgenes and Sel/Int inhibition on neutrophil sequestration and (B) platelet activation.

Abstract# 594

Triple-Knockout Pig Red Blood Cells Are a Potential Alternative Source for Clinical Blood Transfusion

T. Yamamoto[1], M. H. Bikhet[1], H. Q. Nguyen[1], M. Javed[1], D. Ayares[2], H. Iwase[1], H. Hara[1], D. K. Cooper[1], *[1]Xenotransplantation Program, Surgery, The University of Alabama at Birmingham, Birmingham, AL, [2]Revivicor, Blacksburg, VA*

Purpose: Triple-knockout (TKO) pig RBCs (pRBCs) may be an alternative source for clinical blood transfusion because almost humans have no preformed antibody to TKO pRBCs. However, we are still unclear how important the species incompatibility of CD47/SIRP-α affects the result. Old World NHPs (e.g., baboons, rhesus monkeys) have antibodies to TKO pig cells, but capuchin (New World NHPs) monkeys immunologically mimic humans in respect to their response to TKO pig cells. The aim of this study was to determine survival of (i) TKO pRBCs (xenotransfusion) and (ii) of allogeneic monkey RBCs in capuchin monkeys (allotransfusion) after xenotransfusion in capuchin monkeys.

Methods: After 25% of the blood volume was removed from capuchin monkey (n=2), the same volume of carboxyfluorescein diacetate succinimidyl ester (CFSE)-labeled TKO pRBCs was transfused into these monkeys (xenotransfusion). Seven weeks after xenotransfusion, CFSE-labeled allogeneic monkey RBCs were transfused. No immunosuppressive therapy was administered. The percentage of donor blood, complete blood count, IgM/IgG binding, and complement-dependent cytotoxicity (CDC) to TKO pRBCs or allogeneic monkey RBCs were measured after xenotransfusion and allotransfusion. Spleen mononuclear cells were isolated from recipient capuchin monkeys at euthanasia to evaluate direct and indirect phagocytosis of TKO pRBCs or allogeneic monkey RBCs by flow cytometry.

Results: After xenotransfusion, survival of TKO pRBCs was for 5 or 7 days (Fig. A red) even though direct phagocytosis of TKO pRBCs (5.5%) was significantly greater than of allogeneic monkey RBCs (1.6%) ($p<0.01$). After allotransfusion, survival of RBCs was significantly longer at >28 days (Fig. A black). After xenotransfusion, IgM/IgG binding (Figs. B and C) and CDC (Fig. D) to TKO pRBCs increased after days 5 and 7, but there was no further increase after allotransfusion. After xenotransfusion Indirect phagocytosis of TKO pRBCs (10.5%) was significantly greater than of allogeneic monkey RBCs (2.7%) ($p<0.05$).

Conclusions: (1) TKO pRBCs survived in capuchin monkeys for 5 or 7 days without any immunosuppressive therapy. (2) Loss of TKO pRBCs by direct phagocytosis (due to the species incompatibility of CD47/SIRP-α) is less than by indirect phagocytosis and CDC. (3) TKO pRBCs xenotransfusion in primates does not sensitized to subsequent allotransfusion. (4) TKO pRBCs may be life-saving if no human RBCs are immediately available.

Abstract# 595

MiRNA as Regulator of Cell Death and Inflammatory Response in Hepatic Iri

E. Bardhi[1], T. Rousselle[1], J. McDaniels[1], S. Bontha[1], J. Eason[2], D. Maluf[1], V. Mas[3], *[1]Surgery, University of Maryland, Baltimore, MD, [2]Surgery, James D Eason Transplant Institute, Memphis, TN, [3]Surgery, University of Maryland - Division of Surgical Science, Baltimore, MD*

Purpose: Hepatic IRI represents a barrier to the use of available organs. Early graft dysfunction of donor livers is directly related to the severity of hepatic IRI. We aimed to identify upstream regulators of IRI pathways as targets for therapeutics interventions.

Methods: High-throughput gene expression , miRNAs and DNA methylation were done in pre-implantation (L1) and post-reperfusion (L2) biopsies from DDLT recipients. After pre-processing and normalization, differential expressed genes (FDR 0.05, FC>2), miRNAs (FDR 0.05) and CpGs (FDR 0.05, delta>0.20) were identified between groups and at each time point. CpGs were mapped to genes. Integration of significant miRNAs and mRNAs was done using IPA.

Results: Patients presented different extent of IRI post-LT (high (n=20) and low (n=20) IRI groups). CIT was similar between groups (7.4 ± 1.8 vs. 7.1 ± 2.8, p=0.62). Steatosis (%) was statistically different between groups (% steatosis: 25 ± 11.8 vs. 4.1 ± 5.6 ± 3. 4, $p<0.001$). A total of 20 miRNAs in the high IRI group and 26 miRNAs in the low IRI group were statistically differentially expressed (FDR 0.05), of which 7 miRNAs were common to both groups. Differentially expressed miRNAs and mRNAs from same samples were integrated. Within the high IRI group 16 out of 20 differentially expressed miRNAs presented 70 gene targets also differentially expressed in the same samples and following the predicted directionality in expression **(Fig. 1)**. For the low IRI low injury group, 15 out of 26 differentially expressed miRNAs presented 95 gene targets differentially expressed in the same tissue samples. The integrated list of DEGs from the high IRI group when enriched for functions showed activation of cell death (p= 2.9E-04, Z-score 4.7), growth failure (p= 1.4E-03; Z-score 3) and inhibition of transport of molecules (p= 3.23E-03; Z-score 3.02). Analysis from the low IRI injury group showed gene enriched functions mainly related to chemotaxis (p = 1.45E-12, Z-core 2.23), migration of neutrophils (p= 2.69E-05; Z-score 2.41), and T cell development (p= 6.33E-12; Z-score 2.42). Differentially expressed miRNAs were also presenting differentially methylated CpGs at their gene regulatory regions (i.e., MIR17 (TSS1500), MIRLET7A2 (TSS200), MIR144|MIR451 (TSS1500), C9orf3| MIR23B| MIR27B (3UTR|TSS1500).

Conclusions: These preliminary integrative analyses support a role for miRNAs as regulators of pathways of donor organ damage in hepatic IRI and likely targets for intervention.

Abstract# 596

Spleen Tyrosine Kinase (syk): A Novel Regulator of Neutrophil Infiltration in Hepatic Iri

V. Boominathan, A. Kobayashi, S. Duarte, A. Zarrinpar, *Surgery, University of Florida, Gainesville, FL*

Purpose: Hepatic ischemia-reperfusion injury (IRI) plays a governing role in orthotopic liver transplantation, significantly impairing early graft function and increasing organ susceptibility to rejection. Neutrophil activation is a major, but still incompletely characterized, event driving the progression of hepatic IRI. A previously performed multi-omic analysis on post reperfusion liver tissue from a mouse model of hepatic IRI, and human orthotopic liver transplants, identified SYK as a potential mediator of neutrophil activation IRI. Therefore, this study was designed to address the underlying mechanism of Syk signaling pathways that are active and their inflammatory process occurring during hepatic IRI.
Methods: Adult 10-12 week old mice were split in to two groups: treatment with a) Syk inhibitor R788 every day for 5 days prior to IRI, and b) Vehicle everyday for 5 days prior to IRI. Mice in each group were then subdivided in to mice that underwent a 70% partial warm ischemia for 60 minutes, followed by 6 and 24 hours of reperfusion (n=5/group), or mice that were subject only to a sham midline laparotomy (n=3/group). All mice were then euthanized for blood and hepatic tissue collection at each time point. Standard flow cytometry of whole blood was performed with cell specific target markers to identify specific subpopulations.
Results: Specific Syk inhibition depressed neutrophil activation and recruitment in hepatic IRI. Flow cytometric analysis of the circulating CD11b+/Ly6G+ neutrophil cell subset in whole blood retrieved at 6h and 24h post-IRI showed a significantly lower relative % of CD11b+/Ly6G+ neutrophils in mice treated with R788, when compared to those treated solely with vehicle. Inhibiting neutrophil activation was also associated to a significant decrease in the number of liver infiltrating Ly6G+ neutrophils at 6h and 24h post-reperfusion, when compared to vehicle treated control mice. Syk inhibition led to reduced expression of pro-inflammatory iNOS and increased expression of TGF-β at 6h of reperfusion. As a result, mice treated with R788 had significantly reduced serum ALT levels and ameliorated histological hepatic injury at both 6h and 24h of hepatic reperfusion.
Conclusions: This study demonstrates that preconditioning mice with SYK specific inhibition protects livers from hepatic IRI via the downregulation of neutrophil infiltration. Moreover, it demonstrates the potential of multi-omics analysis approach for the identification of novel therapeutic targets in hepatic IRI.

Abstract# 597

Sampling Renal Biopsies in Pre-Clinical Research for Comprehensive Assessment

C. M. Edwards[1], C. Albert[2], D. Stern[1], J. Langford[1], W. Day[2], J. R. DiRito[1], W. M. Saltzman[2], M. Kashgarian[3], J. S. Pober[4], G. T. Tietjen[1], *[1]Surgery, Yale School of Medicine, New Haven, CT, [2]Biomedical Engineering, Yale School of Medicine, New Haven, CT, [3]Pathology, Yale School of Medicine, New Haven, CT, [4]Immunobiology, Yale School of Medicine, New Haven, CT*

Purpose: Previous literature has demonstrated that single biopsies are not representative of a whole kidney in clinical assessments. In this study we aimed to design a statistically powered renal biopsy sampling procedure for pre-clinical research that characterizes the variability of glomerulosclerosis in a kidney.
Methods: Cortical wedge biopsies were obtained from 7 transplant-declined human kidneys in 5 standardized locations. Initial investigation was conducted with 2 kidney pairs. Five sections of 4 μm thickness were spaced at 200 μm along each formalin-fixed biopsy. These sections were stained with H&E and imaged at 20x. The percentage of glomerulosclerosis (%GS) was calculated for each section by counting the ratio of sclerosed glomeruli to total glomeruli. The heterogeneity in %GS within sections, between biopsies, and between paired organs from the same donor was evaluated.
Results: For Kidney Pair 1 (KP1), there was high variability in %GS calculated within a single biopsy, between biopsy locations, and between paired organs. For Kidney Pair 2 (KP2), there was significantly less variability in %GS for these comparisons. KP1 was from a 36-year-old donor, had a Kidney Donor Profile Index (KDPI) of 32, and was expected to be of superior clinical quality compared to KP2 (age 66 and KDPI 95). Interestingly, KP1 demonstrated higher variability in %GS and had higher overall %GS scores compared to KP2.
Conclusions: The findings of our study suggest that limited biopsies, taken for clinical evaluation, may be misleading and alternative approaches, such as imaging, may offer additional information. One biopsy section will not yield a representative value of %GS for an entire kidney or kidney pair. In research settings, the quantity of tissue taken from a kidney is inconsequential because the organ is not being transplanted into a patient. Obtaining multiple biopsies from different anatomic positions and scoring several sections per biopsy is one method for calculating a representative value of %GS. This method may also prove useful for other preclinical endpoints such as immunofluorescence staining or transcriptomics, both of which we are currently evaluating. Further investigation is needed to determine how the biopsy sampling procedure should be adjusted for a given research endpoint based on organ donor health or kidney quality.

Abstract# 598

Indocyanine Green Fluorescence Imaging Allows Quantification of Ischemic Injury During Porcine Normothermic Ex Situ Perfusion

T. Goto, Y. Noguchi, S. Ganesh, L. Mazilescu, T. Reichman, N. Selzner, M. Selzner, *Ajmera Transplant Program, Department of Surgery, Toronto General Hospital, Toronto, ON, Canada*

Purpose: Normothermic Ex Situ Liver Perfusion (NEsLP) is a novel preservation technique for the storage and assessment of grafts retrieved after Donation after Cardio-circulatory Death (DCD). Reliable parameters reflecting graft injury, graft function, and vascular injury during NEsLP are currently missing. Indocyanine Green (ICG) emits fluorescence with near-infrared light and is exclusively cleared by hepatocytes and excreted into the bile without biotransformation. We performed ICG imaging during NEsLP and quantified ICG enhancing and clearance as markers of ischemic liver injury.

Methods: 30 to 35 kg male Yorkshire pigs were allocated to 3 groups; Heart beating donor (HBD), DCD 60minutes and DCD 120minutes, each n=5. Following induction of warm ischemia with heparinization, procurement and 2-hour cold storage, the livers were connected to the NEsLP circuit and ICG was injected via the hepatic artery. ICG enhancement and clearance was measured with the SPY Elite® System (Stryker) and analyzed by Image J (National Institutes of Health) software.

Results: ICG intensity analysis clearly classified three liver patterns (Figure 1A). HBD and DCD60 livers showed rapid intensity increase. Fast clearance of ICG occurred in HBD but not DCD60 livers. DCD120 demonstrated slow enhancement and slow clearance. The arterial ischemic areas were significantly larger in the DCD120 group compared to DCD60 and HBD livers (Figure 1B). ICG excretion rate was significant higher in HBD (69.4%) vs DCD60 (17.5%) vs DCD120 (31.9%) grafts, each $P < 0.0001$) as shown in Figure 1C.

Conclusions: ICG imaging during NEsLP is a novel and non-invasive method for classification of DCD liver grafts, which reflects the impairment of arterial perfusion and the metabolic function in the whole graft.

Abstract# 599

The Harmful Effect of Retained Peripheral Cells During Flushing and Static Cold Storage in Rat Liver Normothermic Machine Perfusion

O. Haque[1], C. A. Pendexter[2], J. F. Markmann[2], K. Uygun[2], H. Yeh[2], S. N. Tessier[2], *[1]Surgery, Beth Israel Deaconess Medical Center, Boston, MA, [2]Massachusetts General Hospital, Boston, MA*

Purpose: Retained donor blood in a liver graft can cause damage to resident cells that is exacerbated by static cold storage (SCS), leading to platelet activation, neutrophil extracellular trap formation, and RBC aggregation at reperfusion. We used normothermic machine perfusion (NMP) to study differences in hepatic function after a variety of flush and SCS conditions.

Methods: Adult, Sprague Dawley rats were heparinized and the livers procured for 6 hours of NMP. Prior to NMP, livers underwent one of the following conditions (n = 4 per group): (1) room temperature (RT) lactated ringers (LR) flush with no SCS, (2) cold University of Wisconsin solution (UW) flush with 24h SCS, (3) RT LR flush with 24h SCS, or (4) no flush with 24h SCS. Perfusion metrics and injury markers were compared by two-way ANOVA testing and histology by H&E and TUNEL staining.

Results: Comparing RT LR flush livers with 24h SCS versus no SCS yielded very similar perfusion results (**fig 1**). Since SCS had no effect on this model, we then compared livers with cold UW flush (group 2), LR flush (group 3), and no flush (group 4), and found, as expected, no flush livers had the highest resistance, lactate, and transaminase levels (**fig 1**). Interestingly, when we compared cold UW flush with RT LR flush, liver allografts flushed with RT LR had lower intrahepatic resistance (0.342 vs. 0.183 mmHg/ml/min, p = 0.007), lactate (7.59 vs. 3.94 mmol/L, p = 0.003), AST (629 vs. 351 U/l, p = 0.046), and ALT (491 vs. 278 U/l, p = 0.068) at 6 hours (**fig 1**). Histology also showed that compared to the cold UW flush livers, the RT LR flush livers had healthier cellular architecture, less endothelial damage, and less TUNEL staining.

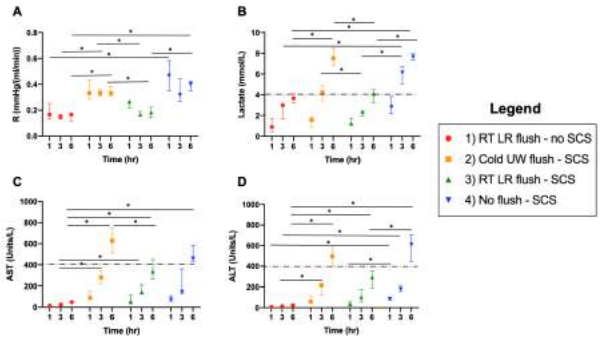

Figure 1: Perfusion and injury metrics of 6 hour ex-vivo rat liver NMP detailing (A) R, intrahepatic resistance, (B) lactate, (C) AST, and (D) ALT. Stars denote p < 0.05 on two-way ANOVA. Icons report median and error bars indicate interquartile range. Horizontal dashed lines indicate transplantable criteria.

Conclusions: Cold UW appears to perform worse than RT LR as a flush, indicating that RT flush prior to cooling may have benefit. Clinically in humans, this would require a cold flush *after* a RT flush, as rat livers cool quickly on ice by virtue of being small. Conventional wisdom suggests that the cold flush should be UW rather than LR because of its preservation properties, but our results suggest that the quality of the flush is more important than the preservation properties. Further studies are needed to compare RT UW to RT LR and cold LR to cold UW flushes to ascertain whether it is UW solution or flush temperature that is damaging the liver allograft.

Abstract# 600

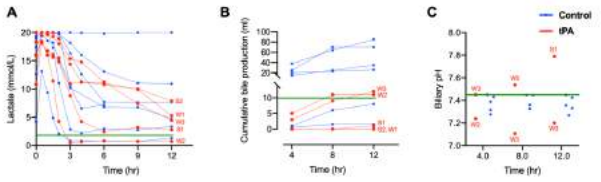
Thrombolytic Therapy During Ex-Vivo Normothermic Machine Perfusion of Human Livers Reduces Peribiliary Vascular Plexus Injury

O. Haque[1], S. Raigani[2], I. Rosales[2], C. Carroll[2], T. M. Coe[2], S. Baptista[2], H. Yeh[2], K. Uygun[2], J. F. Markmann[2], *[1]Surgery, Beth Israel Deaconess Medical Center, Boston, MA, [2]Massachusetts General Hospital, Boston, MA*

Purpose: A major limitation in expanding the use of DCD livers in transplantation are the higher rates of graft failure secondary to ischemic cholangiopathy. Warm

ischemia causes thrombosis and injury to the peribiliary vascular plexus (PVP), which is supplied by branches of the hepatic artery, causing higher rates of biliary complications in DCD allografts. We aimed to recondition discarded DCD livers with tissue plasminogen activator (tPA) while on normothermic machine perfusion (NMP) to improve PVP blood flow and reduce biliary injury.

Methods: Five discarded DCD human livers underwent 12 hours of NMP. Plasminogen was circulated in the base perfusate prior to initiation of perfusion and 1 mg/kg of tPA was administered through the hepatic artery at T=0.5 hours. Two livers were split prior to perfusion (S1, S2), with tPA administered in one lobe, while the other served as a control. The remaining three whole livers (W1-W3) were compared to seven DCD control liver perfusions (C1-C7) with similar hepatocellular and biliary viability criteria (**fig 1**). D-dimer levels were measured at T=1 hour to verify efficacy of tPA. Lactate, total bile production, bile pH, and difference in biliary injury scores before and after perfusion were compared between tPA and non-tPA groups using two-tailed t-tests.



Liver number	S1	S2	W1	W2	W3	C1	C2	C3	C4	C5	C6	C7
Hepatocellular Viability Criteria												
(A) Lactate remains < 1.7 mmol/L w/in 4 hrs of NMP*	N	N	N	Y	N	N	N	N	N	Y	N	N
(B) Total bile production > 10 ml at 4 hrs of NMP*	N	N	N	N	N	Y	N	N	Y	Y	N	Y
Biliary Viability criteria												
(C) bile pH remains > 7.45 w/in 4 hrs of NMP	N	N	N	N	N	N	N	N	N	N	N	N

Figure 1: Viability criteria for donor liver assessment during NMP. (**A**) Inflow lactate levels (**B**) cumulative bile production and (**C**) bile pH in tPA livers (red) and control livers (blue). Green lines indicate viability criteria. **Table** summarizes hepatocellular and biliary viability criteria for transplantation. *Both hepatocellular viability criteria must hold true for a liver to be transplantable. tPA, tissue plasminogen activator. W, whole livers with tPA. S, split liver lobe with tPA. C, whole liver controls without tPA. bPH, biliary pH. Y, yes. N, no.

Results: Average weight-adjusted D-dimer levels were higher in tPA livers in the split (p=0.002) and whole-liver model (p=0.02), verifying drug function. There were no differences in perfusion hepatic artery resistance, portal vein resistance, and arterial lactate between tPA livers and non-tPA livers in both the split and whole-liver model. However, when comparing biliary injury between hepatocellular and biliary non-viable whole livers, tPA livers had significantly lower PVP injury scores (0.67 vs. 2.0, p=0.01) and mural stroma (MS) injury scores (1.3 vs. 2.7, p=0.05) (**fig 2**).

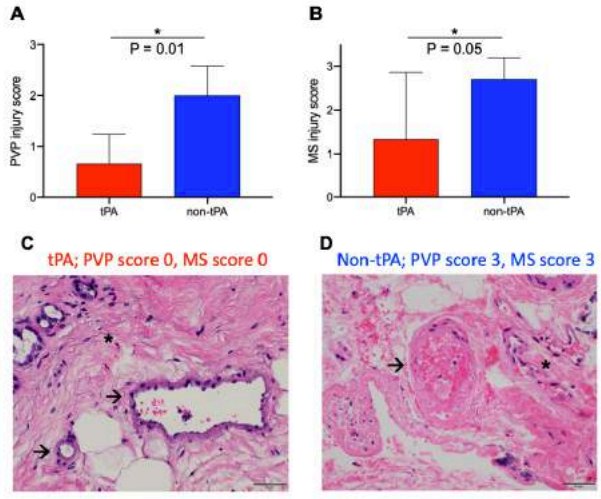


Figure 2: Difference in bile duct injury scores before and after 12 hours of NMP between whole, non-viable tPA livers (red) and whole, nonviable control livers (blue). tPA livers exhibit less (**A**) peribiliary vascular plexus (PVP) injury ($p = 0.01$) and (**B**) mural stroma (MS) injury ($p = 0.05$). Stars denote statistical significance on two-tailed, unpaired t-test: *$p \leq 0.05$. Error bars denote standard deviation. Representative H&E histology of tPA liver (**C**) shows normal peribiliary arterioles (arrows) and no injury to MS (asterisk) versus non-tPA liver histology (**D**) shows arteriolonecrosis (arrow) and necrotic mural stroma (asterisk).

Conclusions: This study demonstrates that administration of tPA into DCD livers during NMP can reduce PVP and MS injury. Further studies are necessary to assess the effect of tPA administration on long term biliary complications.

Abstract# 601

Sigma-1 Receptor Agonists are Renoprotective in Experimental Kidney Transplantation

A. Hosszu[1], T. Lakat[1], A. Toth[1], D. Balogh[1], J. Hodrea[1], L. J. Wagner[2], A. J. Szabo[1], A. Fekete[1], *[1]1st Department of Pediatrics, Semmelweis University, Budapest, Hungary, [2]Department of Transplantation and Surgery, Semmelweis University, Budapest, Hungary*

Purpose: Kidney transplantation (Tx) is associated with better quality of life and reduced costs compared to dialysis, but the shortage in donor organs is a limiting factor. Graft survival is highly dependent on the extent of ischemia/reperfusion injury (IRI) during Tx. We recently described the renoprotective effects of Sigma-1 receptor (S1R) agonist treatment in renal IRI. Thus, our aim was to develop a preservation solution which minimizes ischemic graft damage in order to improve Tx outcomes and to increase the number of organs suitable for Tx.

Methods: Kidneys of male Wistar rats were perfused and placed in ice cold (i) Custodiol preservation solution; Custodiol containing S1R agonists (ii) fluvoxamine; (iii) SA-4503 or (iv) VCC compound for 2 hours, then autotransplanted and sacrificed 24 hours or 9 days after reperfusion. Sham-operated rats served as controls. In a second experiment kidneys wild-type and S1R knockout mice were perfused and placed in ice cold Custodiol or Custodiol containing various selective S1R agonists for 2/3/8/24 hours of cold ischemia and tissue samples were collected for histological evaluation.

Results: S1R agonists mitigated renal functional impairment and tubular dilatation following Tx. Expression of early and sensitive tubular injury markers *Kim1* and *Ngal* were markedly less elevated in S1R agonist-treated kidneys. S1R agonists alleviated renal apoptosis as shown on TUNEL-stained kidney sections, decreased apoptotic *Bax* expression, while increased anti-apoptotic *Bcl2* expression. Reduced number of CD45+ leukocytes and reduced inflammatory cytokine (*Mcp1, Il1a, Il6, Tnf*) expressions confirmed the anti-inflammatory effect of S1R agonists. All S1R agonists mitigated cold ischemic structural kidney damage at all time points.

Conclusions: The addition of S1R agonists to the preservation solution during Tx improves graft function and alleviates structural damage, thus improving long-term outcomes. S1R agonists reduce graft injury during cold storage, therefore the number of transplantable donor organs can be increased.

Abstract# 602

An Immune-modulatory Strategy to Mitigate Hepatic Ischemia/reperfusion Injury in a Murine Model

A. Kobayashi, A. Wanchoo, S. Farhadi, J. Simonovich, S. Duarte, V. Boominathan, S. Shrestha, G. Hudalla, B. G. Keselowsky, A. Zarrinpar, *University of Florida, Gainesville, FL*

Purpose: Hepatic ischemia/reperfusion injury (IRI) is the leading cause of early graft dysfunction and contributes to the shortage of donor liver grafts. However, despite its obvious clinical importance, there are no effective therapies to prevent or treat this condition. Indoleamine 2,3-dioxygenase (IDO) is an intracellular enzyme that catalyzes the catabolism of the essential amino acid tryptophan to the product kynurenine. It is well known for inducing a powerful immunosuppressive metabolic programming. To date, studies have mostly focused on prolonging graft survival by overexpressing IDO in the transplanted tissue. PEGylation of therapeutic proteins reduces their immunogenicity and extends systemic circulation time. Here, we PEGylate IDO and evaluate efficacy and safety of this IDO delivery strategy to control the local hepatic inflammatory response in a mouse model of warm hepatic IRI

Methods: We used a well-established mouse model of partial hepatic IRI. Partial hepatic ischemia was produced in the left and median lobes for 90 minutes followed by 6 hours reperfusion. Male 8-12 week old Balb/c mice were separated into 3 cohorts; PEGylated-IDO (PEG-IDO), IDO, and phosphate buffered saline (PBS) intravenously administered 48 hours prior to inducing ischemic injury.

Results: PEGylated-IDO significantly improved hepatic IRI; plasma levels of aspartate alanine aminotransferase and alanine aminotransferase at 6 hours after reperfusion were significantly lower in the PEG-IDO group, when compared with those in PBS group ($P<0.05$). Histological analysis showed significantly less congestion, necrosis, and vacuolization in the PEG-IDO group compared with those in PBS groups ($P<0.05$) as assessed by Suzuki score. It decreased the local infiltration of the inflammatory cells such as T cells, neutrophils, and macrophages, and it re-

duced the expression of proinflammatory cytokines and chemokines. Furthermore, apoptosis, as measured by the number of TUNEL+ hepatocytes, was also suppressed in PEG-IDO treated mice.

Conclusions: The results in this study indicate that PEG-IDO preconditioning protects livers from local inflammation and liver damage induced by hepatic IRI. This metabolic immune-modulatory approach may be a new therapeutic strategy against innate immunity-dominated liver tissue damage.

Abstract# 603

Nanodiamond-doxorubicin Complexes Improve Hepatic Ischemia/reperfusion Injury

A. Kobayashi, C. Grady, S. Duarte, V. Boominathan, S. Shrestha, A. Zarrinpar, *Surgery, University of Florida, Gainesville, FL*

Purpose: Hepatic ischemia/reperfusion injury (IRI) is a major inflammatory event in liver transplantation that is mediated by oxidative stress. Doxorubicin (DOX) can mitigate oxidative stress by inducing the expression of heme oxygenase-1; however its clinical use in IRI has been hampered by significant systemic toxicity. Nanodiamonds (ND) are carbon nanoparticles with potential to be high-affinity carriers for the selective delivery of anthracyclines, such as DOX, and thus mitigate the negative effects of systemic delivery. Here, we use ND-adsorbed DOX (NDX) and evaluate its efficacy in a mouse model of hepatic IRI.
Methods: We used a well-established mouse model of partial hepatic IRI. Partial hepatic ischemia was produced in the left and median lobes for 90 minutes followed by 6 hours reperfusion. Male 8-12 week old Balb/c mice were separated into 6 cohorts; High-DOX (1mg/kg), Low-DOX (0.5mg/kg), ND, High-NDX (1mg/kg equivalent of DOX), Low-NDX (0.5mg/kg equivalent of DOX) and phosphate buffered saline (PBS) were intravenously administered 48 hours prior to inducing ischemic injury.
Results: Plasma levels of aspartate alanine aminotransferase (AST) and alanine aminotransferase (ALT) at 6 hours after reperfusion were significantly lower in High-DOX and Low-NDX treated mice, when compared with those in PBS treated mice ($P<0.05$ and $P<0.05$, respectively). AST and ALT levels of the High-DOX and Low-NDX treated mice were comparable. Histological analysis showed significantly less congestion, necrosis, and vacuolization in the High-DOX and Low-NDX group compared with those in PBS groups as assessed by Suzuki score ($P<0.05$ and $P<0.01$, respectively). High-DOX and Low-DOX decreased the local infiltration of the inflammatory cells such as T cells, neutrophils, and macrophages, and it reduced the expression of proinflammatory cytokines and chemokines.Furthermore, apoptosis, as measured by the number of TUNEL positive hepatocytes, was also suppressed in PEG-IDO treated mice.
Conclusions: The results in this study indicate that NDX complexes protects mice from local inflammation and liver damage induced by hepatic IRI with half the DOX dose. These results support the development of a more clinically effective strategy for DOX in liver transplantation.

Abstract# 604

Hepatic Ferroptosis in Cold Stress and Warm Ischemia-reperfusion: A Novel Therapeutic Target in Liver Transplantation

H. Kojima[1], H. Hirao[1], K. Kadono[1], T. Ito[1], K. J. Dery[1], S. Kageyama[2], K. Nakamura[3], F. M. Kaldas[1], D. G. Farmer[1], J. W. Kupiec-Weglinski[1], *[1]UCLA Medical Center, Los Angeles, CA, [2]Kyoto University, Kyoto, Japan, [3]Nishi-Kobe Medical Center, Kyoto, Japan*

Purpose: Ferroptosis, a newly discovered programmed cell death platform, due to iron-dependent accumulation of lipid peroxides, has been reported to aggravate ischemia-reperfusion (IR) injury in various organs, including heart, kidney, and intestine. Nevertheless, little is known about the contribution of ferroptosis in liver transplantation. In the current study, we investigated the functional role of ferroptosis signaling during liver cold storage and warm IR, and evaluated its pathogenic effects in mouse and human orthotopic liver transplantation (OLT).
Methods: Fifty adult human OLT patients were recruited under IRB protocol. Liver graft biopsies (pre-reperfusion and 2h post-reperfusion) were screened based on levels of glutathione peroxidase 4 (GPX4), the key ferroptosis regulator. Hepatocytes and liver sinusoidal endothelial cells (LSECs) isolated from C57BL/6 mice were subjected to cold stress or warm hypoxia/reoxygeneration (H/R). Further, we used ferroptosis inhibitor (ferrostatin-1) in the liver storage solution or in mouse recipients to evaluate its therapeutic effect in OLT settings.
Results: The GPX4 expression in human liver biopsies negatively correlated with pro-inflammatory host immune cell activation markers. The anti-inflammatory phenotype in high GPX4 recipient group coincided with improved hepatocellular function (decreased AST levels) post-OLT, suggesting ferroptosis inhibition might reduce OLT injury in humans.During cold stress, increased GPX4 expression was observed in cultured murine LSECs but not hepatocytes. In contrast, the hepatocyte GPX4 expression increased during warm H/R, coinciding with increased hypoxia-inducible factor 1-alpha (HIF-1α) levels. In mouse OLT model, the hepatocellular damage was mitigated in liver grafts preserved with ferrostatin-1, a ferroptosis inhibitor. In addition, systemic administration of ferrostatin-1 to recipient mice reduced OLT injury.
Conclusions: Inhibition of ferroptosis during donor liver cold preservation protected LSECs, resulting in alleviation of hepatic IR-stress after OLT. The beneficial effects of ferroptosis inhibition during warm IR resulted from hepatocyte cytoprotection. This study provides the basis for novel therapeutic strategies by targeting ferroptosis cell death during both, cold liver preservation and in OLT recipients.

Abstract# 605

Augmented Responses of Donor Kidney Tubular Cells to TLR Signaling Correlate with Ameliorated Ischemia/reperfusion Injury and Long-term Allograft Protection

X. Lai[1], J. Wang[1], L. Qiu[2], S. Han[1], K. Shen[1], Z. Zhang[1], *[1]Comprehensive Transplant Center, Microsurgery core, Northwestern University, Chicago, IL, [2]University of California, San Francisco, San Francisco, CA*

Purpose: We have previously demonstrated that donor genetic background and kidney-intrinsic innate immunity were key determinants of delayed graft function in kidney transplantation. However, the long-term effect and mechanism of ischemia/reperfusion injury (IRI) on graft rejection remains unclear.
Methods: Kidneys from C57BL/6 (B6) or Balb/c mice were harvested and stored in cold UW solution for 3 hours, and then were transplanted into bi-nephrectomized C3H mice. Graft survival, renal function, pathological change of grafts, immunophenotypic analysis, and expression of involved genes, were determined. Renal tubular epithelial cells (RTECs) isolated from B6 or BALB/c mouse kidneys were stimulated by lipopolysaccharide (LPS) or Pam3CSK4, and cytokines and kidney injury molecule-1 (KIM-1) in supernatant were measured.
Results: We found that when cold ischemia time was prolonged to 3 hours, rejection occurred earlier in kidney grafts from B6 mice compared with grafts from Balb/c mice. Correspondingly, recipients received B6 kidneys exhibited more severe impaired renal function, higher hematocrit level and more weight loss than recipients received Balb/c kidneys within 14 days post transplantation. Furthermore, B6 kidney grafts showed more severe histological impairment, increased $Ly6C^{+}CCR2^{+}CX3CR1^{+/-}$ inflammatory monocyte and CD8 memory T cell infiltration, accompanying by upregulation of IL-6 and endoplasmic reticulum stress genes. *In vitro* studies revealed that, in responding to either LPS (TLR4 agonist) or Pam3CSK4 (TLR1/TLR2 agonist) stimulation, RTECs from B6 mice produced lower level of cytokines including IL-6, IL-10, TNFα and MCP-1, but significantly higher level of the tubular cell injury marker KIM-1, in comparison with RTECs from Balb/c mice. Taken together, these results indicate that Balb/c kidneys were less vulnerable to IRI-induced rejection than B6 kidneys, which involves in activation of TLR depending innate immunity.
Conclusions: We conclude that augmented responses of donor kidney tubular cells to TLR signaling plays a pivotal role in ameliorated ischemia/reperfusion injury and long-term allograft protection.

Abstract# 606

Caspase-3 is a Predominant Regulator of Microvascular Dysfunction and Aki-ckd Transition Post Renal Ischemia-reperfusion Injury

S. Lan, F. Migneault, J. Turgeon, M. Bourgault, M. Dieudé, N. Patey, H. Cardinal, M. Hébert, *CRCHUM, University of Montreal, Montreal, QC, Canada*

Purpose: Ischemia-reperfusion injury (IRI) is a major risk factor for chronic renal failure. Caspase-3, an effector responsible for apoptosis execution, is activated within tubular epithelial structure and peritubular capillaries (PTC) in the early stage of IRI-induced acute kidney injury (AKI). We previously characterized the different cell deaths in tubular and microvascular compartments of IRI-induced acute kidney

injury (AKI) and their relative importance on microvascular rarefaction and renal fibrogenesis in mild AKI. Here, we further characterize the role of caspase-3 in microvascular dysfunction and progressive renal failure in both mild and severe AKI.
Methods: Unilateral renal artery clamping for 60 minutes with contralateral nephrectomy was performed in both wild-type (C57BL/6) or caspase-3-/- mice.
Results: In the severe AKI model (60 minutes clamping), caspase-3-/- mice showed reduced PTC endothelial cell loss, decreased PTC collagen deposition, and α-SMA expression, and lower tubular injury scores on the long-term when compared to wild-type animals. Preservation of the peritubular microvasculature in caspase-3-/- mice led to reduced tubular ischemia, with lower hypoxia-inducible factor 1α (HIF1α) expression. Besides, intra-vital imaging and micro Computed Tomography (microCT) revealed preserved PTC permeability and better terminal capillary density in caspase-3-/- mice. Caspase-3-/- mice with severe IRI also showed better preservation of long-term renal function.
Conclusions: Collectively, these results demonstrate the pivotal importance of caspase-3 in regulating long-term renal function after IRI and establish the predominant role of PTC dysfunction as a major contributor to progressive renal dysfunction.

Abstract# 607

Combining Oxygenated Cold Perfusion with Normothermic Ex-vivo Perfusion Improves the Outcome of DCD Porcine Kidney Transplantation

L. I. Mazilescu[1], T. Goto[1], R. Rosales[1], Y. Noguchi[1], P. Urbanellis[1], L. A. Robinson[2], M. Selzner[1], *[1]Ajmera Transplant Program, Toronto General Hospital, Toronto, ON, Canada, [2]Department of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada*

Purpose: Ex-vivo machine perfusion is a novel preservation technique for the storage and assessment of marginal kidney grafts. Normothermic (NEVKP) as well as hypothermic machine perfusion (HMP) with and without oxygen have been developed in the recent past. All ex-vivo perfusion techniques have advantages and shortcomings. NEVKP reduces cold ischemic injury with opportunities for graft assessment. In contrast, HMP is easier to perform during transportation, but graft assessment is limited. In the current study, we assessed if a combination of oxygenated HMP (oxHMP) followed by a short NEVKP period could combine the advantages of both preservation techniques.
Methods: All pig kidneys were exposed to 30min of warm ischemia followed by ex-vivo perfusion. Three ex-vivo perfusion techniques were compared. Kidneys either underwent 16hr NEVKP or were preserved by 16hr oxHMP. The third group was treated with 16hr oxHMP followed by 3hr NEVKP (oxHMP+NEVKP group). After contralateral nephrectomy, grafts were autotransplanted and animals were followed for 8 days. Kidney function and injury markers were compared between groups.
Results: All animals survived the follow-up period. Grafts preserved by continuous NEVKP showed improved function with lower peak serum creatinine (SrCrea) and more rapid recovery compared to the other two groups (peak SrCrea NEVKP vs oxHMP vs oxHMP+NEVKP: 3.7±1.3mg/dl vs 9±5.5mg/dl vs 3.9±1.4mg/dl). The differences in daily SrCrea levels reached significance between NEVKP and oxHMP on POD 7 and 8 (both $p<0.05$) and between NEVKP and oxHMP+NEVKP on POD1 ($p=0.04$). Similarly, there was a significant difference in daily SrCrea between oxHMP+NEVKP and oxHMP on POD1, 2 and 7 (all $p<0.05$). On POD3, creatinine clearance was increased in the NEVKP and oxHMP+NEVKP group (NEVKP vs oxHMP vs oxHMP+NEVKP: 41±19mL/min vs 13±13mL/min vs 29.4±11.5mL/min, $p=0.034$). Urine neutrophil gelatinase-associated lipocalin, as a marker of kidney injury, was significantly lower on POD 3 in the oxHMP+NEVKP group compared the other two groups ($p=0.0021$).
Conclusions: A short period of NEVKP following oxHMP provides the same outcomes as prolonged NEVKP in DCD kidney transplantation and is superior to oxHMP alone. A combination of oxHMP with end-ischemic NEVKP could be an attractive practical strategy to combine the advantages of both preservation techniques.

Abstract# 608

Tubastatin-a Mediated Protection from Liver Injury is Preserved in a Lymphocyte Deficient Model

C. S. O'Brien[1], P. Hernandez[1], Z. Wang[1], G. Ge[1], A. Kozikowski[2], W. Hancock[1], M. H. Levine[1], *[1]University of Pennsylvania, Philadelphia, PA, [2]University of Illinois at Chicago, Chicago, IL*

Purpose: Liver Ischemia reperfusion injury (IRI) and Acetaminophen (APAP) toxicity are important causes of acute liver failure in the United States, that lack effective therapy. Histone deacetylases (HDACs) are enzymes that alter gene expression, regulating diverse cellular processes. We have previously shown that Tubastatin-A (TubA), an HDAC6 inhibitor, provides protection from hepatic IRI and APAP toxicity. We now report that the protective effect of TubA is preserved in a lymphocyte deficient model.
Methods: Female Rag-1 -/- mice were treated with vehicle or TubA, at 16 hours and one hour prior to either 60 minutes of warm IRI or administration of APAP (500 mg/kg). Serum ALT and AST were measured in each group 24 hours after IRI or APAP administration.
Results: Liver IRI in Rag-1 -/- mice resulted in a significant injury (AST 13,196 +/-2410, ALT 6851 +/-2953), with TubA treatment resulting in significantly lower AST (AST 4272 +/-3411, $p=0.02$, ALT 2991 +/-2309, $p=0.06$) (Figure 1). APAP toxicity in Rag-1 -/- mice resulted in significant injury as well (AST 16,251 +/- 6142, ALT 9363 +/- 2899). TubA treatment resulted in significantly lower AST/ALT (AST 778 +/-600, $p=0.008$ ALT 889 +/- 834, $p=0.008$) (Figure2).
Conclusions: TubA provides protection from both liver IRI and APAP toxicity. This protection is maintained in lymphocyte deficient mice, suggesting that TubAs mechanism of action is not via the lymphocytes. Further understanding of the mechanism of TubA will assist in the treatment of liver injury.

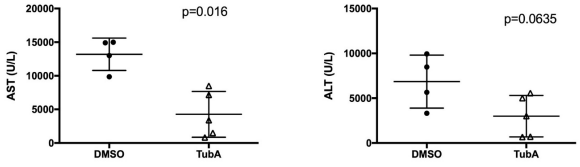

Figure 1. AST and ALT for Rag-1 -/- mice 24 hours after 60 minutes of liver IRI

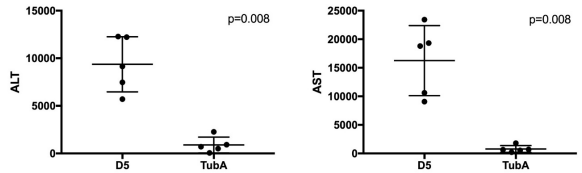

Figure 2. ALT and AST in Rag-1 -/- mice 24 hours following APAP toxicity

Abstract# 609

Effect of Defibrotide on Kidney Ischemia Reperfusion Injury in a Preclinical Renal Transplant Model

P. Pine[1], Z. Sun[2], A. Matas[3], J. Shi[1], A. Ebrahimnejad[1], M. Zanette[4], P. Halloran[5], J. S. Bromberg[6], R. Hanvesakul[7], *[1]Jazz Pharmaceuticals, Palo Alto, CA, [2]Johns Hopkins Medicine, Baltimore, MD, [3]Univ of Minnesota, Minneapolis, MN, [4]Jazz Pharmaceuticals, Philadelphia, PA, [5]Univ of Alberta, Edmonton, AB, Canada, [6]Univ of Maryland School of Medicine, Baltimore, MD, [7]Jazz Pharmaceuticals, Oxford, United Kingdom*

Purpose: Ischemia reperfusion injury (IRI) is a major contributor to graft failure. During organ removal and preservation, ischemia results in anaerobic respiration and cellular damage. At time of renal transplant (tx), oxygen is restored in aerobic respiration; injury is caused by generation of reactive oxygen species and inflammatory cytokines. Cellular activation caused by IRI results in an immune response, leading to further kidney damage. *In vitro* studies have shown that defibrotide (DF) stabilizes and protects endothelial cells through anti-inflammatory and antioxidant mechanisms. This study investigated the potential of DF to prevent kidney damage from IRI.

Methods: A beagle dog autologous renal tx model was used to evaluate DF on kidney IRI without immunosuppression. For all dogs, on Day 0, the left kidney was removed, flushed, placed in cold preservation solution (CPS) for 32h, and then transplanted to the same dog. At tx, the right kidney was removed. Control dogs (Group [Gp]1, n=8) received intravenous (IV) saline (4 mL/kg/h). Gp2 (n=8) received IV DF (50 mg/kg/dose q.i.d.) 2h before tx and immediately after tx, continuing until study end (Day 8). For Gp3 (n=8), the kidney was flushed with DF in CPS at removal and IV DF was given as in Gp2. Assessments included histology and daily clinical chemistry. Mixed effects models with repeated measures were used; nominal *P* values are comparing each DF Gp with control. Histology was assessed qualitatively.

Results: The combination of DF in CPS flush and IV DF pre-/post-tx reduced elevations of serum creatinine (P=0.0058), urea (P=0.0061), and potassium (P<0.0001), and stabilized urine output (P=0.0124) post-tx compared to controls. Results for IV DF alone were not significant compared to control. Histology revealed that kidneys from Grp 3 DF-treated dogs had reduced tubular necrosis, interstitial fibroplasia, and hemorrhage vs controls.

Conclusions: In this preclinical dog model, when DF was in flush/CPS and given pre-/post-tx, there was reduced renal impairment, tubular necrosis, interstitial fibroplasia, and hemorrhage vs controls. These results support further DF evaluation in preventing kidney IRI.

Abstract# 610

Composition of Ex Vivo Lung Perfusion Solutions and Kinetics Define Differential Cytokine and Chemokine Secretion in a Porcine Cardiac Arrest Model of Lung Preservation

L. M. Radomsky[1], A. Koch[2], C. Olbertz[2], J. F. Kuehne[1], Y. Liu[2], J. Keil[1], K. Beushausen[1], U. Rauen[3], C. S. Falk[1], M. Kamler[2], *[1]Institute of Transplant Immunology, Hannover Medical School, Hannover, Germany, [2]Thoracic Transplantation, Department of Thoracic and Cardiovascular Surgery, University Hospital Essen, Essen, Germany, [3]Institute of Physiological Chemistry, University Hospital Essen, Essen, Germany*

Purpose: Ex vivo lung perfusion is an innovative technique to evaluate marginal lung organs especially after DCD. Normothermic continuous perfusion should reduce ischemic damage and improve the outcome of lung transplantation. However, the optimal protocol for EVLP has not been defined so far. The aim of our study was to compare cytokine/chemokine concentrations in perfusion solutions using different kinetics and solution compounds of EVLP in a porcine cardiac arrest model and to correlate the inflammatory parameters to oxygenation capacity values (ΔpO2).

Methods: Following cardiac arrest and 1h of warm ischemia, lungs were harvested and flushed. Groups were processed as immediate (I-EVLP) 1h cold static preservation (CSP) and delayed (D-EVLP; 9h CSP). D-EVLP lungs were perfused with different solutions: Steen vs. modified Custodiol-N containing dextran (CD) or dextran/albumin (CDA). Cytokine/chemokine levels were analyzed at baseline (0h), after 1h, 4h using multiplex protein arrays.

Results: Concentrations of TNF-α, IL-6, CXCL8, IFN-γ, IL-1α and IL-1β increased significantly ($p<0.05$) in all four groups. CD-solution contained lower levels of these proteins and IL-2, IL-12, IL-10, IL-4, IL-1RA and IL-18 ($p<0.05$) compared to SteenSolution samples. Protein concentrations correlate negatively with ΔpO2 values ($p<0.05$). No significant differences could be detected between I- vs. D-EVLP lungs and CD vs.CDA solutions.

Conclusions: In a non-heart beating porcine cardiac arrest model with relevant IRI, lungs were perfused with normothermic EVLP. Longer CSP prior to EVLP did not result in enhanced cytokine secretion, but the first hours of reperfusion seem crucial for tissue damage. CD-solution dampens the cytokine/chemokine secretion probably by iron chelators and, possibly, protecting effects of dextran. Addition of albumin had no further effect on inflammation. Cytokine/chemokine concentrations correlated negatively with the oxygenation capacity, an important parameter for organ acceptance. These finding may help to optimize the ex vivo preservation procedure and possibly, more organs could reach the clinically relevant threshold for transplantation, thus, the pool of marginal donor lungs could be enlarged.

Abstract# 611

Inhibition of Apoptosis During Ex Situ Liver Normothermic Machine Perfusion Decreases Reperfusion Injury and Improves Viability

S. Raigani[1], S. Baptista[1], A. Ohman[2], J. Santiago[2], I. Rosales[1], M. Heaney[2], J. Boylan[2], T. Coe[1], K. Uygun[1], J. Sanders[2], H. Yeh[1], *[1]Transplant Surgery, Massachusetts General Hospital, Boston, MA, [2]Pediatric Endocrinology, Brown University, Providence, RI*

Purpose: Normothermic machine perfusion (NMP) is an ideal platform for delivery of novel therapeutics aimed at rehabilitation of discarded or marginal livers. We examined the efficacy of inhibiting apoptosis during NMP as a means of mitigating ischemia-reperfusion injury (IRI) and improving liver viability.

Methods: 5 human livers from donation after circulatory death (DCD), turned down by all regional transplant centers, underwent 12 hours of NMP with the addition of an irreversible pan-caspase inhibitor, emricasan, at a dose of 5mg/kg liver. Liver viability during NMP was assessed using criteria established by Mergental et al. Outcomes

were compared to two control groups of discarded DCD livers stratified by viability (Table 1). Subgroup analysis was performed by stratifying the treatment group into low and high donor risk index (DRI) groups. RNA sequencing was performed on sequential liver biopsies. Median with interquartile range (IQR) reported for all data.
Results: Nonviable control livers demonstrated significantly higher markers of apoptosis (cleaved cytokeratin 18, caspase-3/7 activity) than viable control livers during NMP (Fig. 1A). Addition of emricasan significantly decreased apoptosis. Emricasan-treated livers further demonstrated decreased IRI markers (Interleukin-6, interferon-gamma, cell-free DNA, Fig. 1B). Median DRI in the high DRI treated group was 3.0 (IQR 2.8,3.6) compared to 2.4 (2.2,2.4) in nonviable control livers (p=0.099). Despite the increased ischemic injury, 2 of 3 high DRI treated livers met viability criteria compared to 0/5 (p=0.035). There was no evidence of deleterious drug effect in the low DRI treated livers.
Conclusions: The magnitude of apoptosis appears to be associated with graft viability during NMP. A single dose of the pan-caspase inhibitor, emricasan, decreased apoptosis and markers of IRI and appeared to improve graft viability within 6 hours of NMP. Therapeutic inhibition of apoptosis may be a simple and effective method for improving graft utilization and minimizing graft dysfunction.

Table 1 - Donor Liver Demographics

	Emricasan		Control Viable	Control Nonviable
	Low DRI (n=2)	High DRI (n=3)	(n=6)	(n=5)
Warm ischemic time (min)	22.5 (22-23)	32 (23-53)	27.5 (24-28)	24 (23-34)
Cold ischemic time (min)	450 (347-553)	703 (679-758)	625.5 (458-697)	358 (357-367)
Age	27 (26-28)	59 (50-60)	58.5 (40-60)	56 (55-59)
Donor risk index	1.6 (1.5-1.7)	3.0 (2.8-3.6)	2.1 (1.9-2.2)	2.4 (2.2-2.4)

Abstract# 612

The Contribution of Disulfide-hmgb1 Released During Ischemia-reperfusion Injury to Pro-inflammatory Macrophage Polarization Following Liver Transplantation

A. Q. Terry, R. A. Sosa, M. Rossetti, J. Nevarez-Mejia, B. V. Naini, F. Kaldas, V. Groysberg, S. Younan, R. Busuttil, D. W. Gjertson, J. W. Kupiec-Weglinski, E. Reed, *Pathology and Lab Medicine, UCLA, Los Angeles, CA*

Purpose: Ischemia-reperfusion injury (IRI) during liver transplantation (LT) is a pro-inflammatory response linked to poorer outcomes, including increased alloimmunity, post-LT. We previously showed that post-reperfusion portal vein blood (liver flush; LF) from IRI+ LT patients activates TLR4 and induces pro-inflammatory macrophages and that disulfide HMGB1 (diS HMGB1), whose receptors include TLR4, is increased in IRI+ patients. This study aimed to determine the contribution of diS HMGB1-TLR4 signaling to pro-inflammatory macrophage polarization and function and to the previously-observed IRI+ polarized macrophage phenotype.
Methods: Third-party monocytes were exposed to diS HMGB1 or LPS with or without TAK-242, a TLR4 inhibitor, for 5 days. Surface markers (CD66a, CD86, HLA-DR, PD-L1, TIM-3) and ROS production were analyzed by flow cytometry. Secreted cytokines were analyzed via 38-plex Luminex. Surface marker expression was compared to phenotypes induced by LF from LT patients during previous studies.
Results: diS HMGB1 mirrored the IRI+ LF macrophage phenotype in 4/5 markers (high HLA-DR, CD86; low PD-L1, CD66a). diS HMGB1 trended with LPS for 1/5 markers (CD66a). High TIM-3 induced by diS HMGB1 mirrored TIM-3 expression induced by IRI- LF. TAK-242 had a dose-dependent effect on 4/5 markers (all but CD66a) for the LPS phenotype but only 1/5 markers (HLA-DR) for the diS HMGB1 phenotype. diS HMGB1 induced higher ROS production than LPS; TAK-242 only affected LPS-induced ROS production. TAK-242 also had a dose-dependent inhibition on 35 LPS-induced cytokines, but only inhibited 4 diS HMGB1-induced cytokines (IL-6, FGF2, MIP1a, and MIP1b).
Conclusions: diS HMGB1 induces a pro-inflammatory macrophage phenotype with increased antigen presentation (high CD86 and HLA-DR), decreased T-cell inhibition (low PD-L1 and CD66a), high ROS production, and pro-inflammatory cytokine secretion capabilities. However, only HLA-DR expression and IL-6, FGF2, MIP1a, and MIP1b secretion were affected by inhibition of TLR4 signaling. This data suggests that 1) diS HMGB1 contributes to the post-LT immune response in IRI+ patients, 2) these macrophages can contribute to inflammation and alloimmunity post-LT, and 3) the observed diS HMGB1 phenotype is not completely dependent on TLR4. This study reveals that diS HMGB1 released during IRI can polarize macrophages to become pro-inflammatory and contribute post-LT inflammation in IRI+ patients.

Abstract# 613

Myeloid YAP-HSF1 Signaling Inhibits NLRP3 Function and RIPK3-mediated Hepatocyte Necroptosis in Liver Ischemia and Reperfusion Injury

Y. Tian, D. Xu, M. Sheng, Y. Zhan, Y. Lin, C. Li, A. J. Coito, R. W. Busuttil, D. G. Farmer, J. W. Kupiec-Weglinski, B. Ke, *Surgery, Dumont - UCLA Transplant Ctr, Los Angeles, CA*

Purpose: Yes-associated protein (YAP), a downstream effector of the Hippo pathway, tightly regulates cell growth, survival, and tissue inflammation. Activation of heat shock factor 1 (HSF1) has a profound impact on innate immunity during liver inflammatory response. However, it remains unknown as to whether and how the myeloid YAP-HSF1 signaling may control NLRP3 activation in sterile inflammation during liver injury. This study investigated the mechanistic link between YAP and HSF1 in the modulation NLRP3-mediated innate immune response in liver ischemia and reperfusion injury (IRI).
Methods: Myeloid-specific YAP knockout ($YAP^{M\text{-}KO}$) and floxed YAP ($YAP^{FL/FL}$) mice (n=6/group) were subjected to 90 min partial liver warm ischemia followed by 6 h of reperfusion. In parallel *in vitro* study, bone marrow-derived macrophages (BMMs) were isolated from these conditional knockout mice and transfected with CRISPR/Cas9-mediated HSF1 knockout (KO) vector followed by LPS (100 ng/ml) stimulation.
Results: Ischemia/reperfusion (IR) stress induced YAP and HSF1 activation evidenced by increased nuclear YAP and HSF1 expression in hepatic Kupffer cells. Myeloid YAP deficiency exacerbated IR-induced liver damage, with increased serum ALT levels, macrophage/neutrophil accumulation, and pro-inflammatory cytokine/chemokine production compared to the $YAP^{FL/FL}$ controls. Unlike in the $YAP^{FL/FL}$ controls, $YAP^{M\text{-}KO}$ enhanced TXNIP, RIPK3, p-MLKL, NEK7, NLRP3, ASC, cleaved caspase-1 activation in ischemic livers. However, adoptive transfer of lentivirus HSF1-modified macrophages into mice markedly improved liver function with reduced TXNIP, RIPK3, p-MLKL, and NEK7/NLRP3 but augmented TRX1 in IR-challenged livers. Moreover, disruption of RIPK3 in $YAP^{M\text{-}KO}$ mice with an *in vivo* mannose-mediated RIPK3 siRNA delivery system diminished IR-triggered hepatocyte death. *In vitro* studies showed that macrophage YAP and HSF1 co-localized in the nucleus whereby HSF1 interacted with YAP in response to LPS stimulation. Disruption of HSF1 with a CRISPR/Cas9 HSF1 KO transfection in $YAP^{FL/FL}$ macrophage augmented TXNIP and RIPK3 activation leading to enhanced NEK7/NLRP3 function and RIPK3-mediated hepatocyte necroptosis after macrophage/hepatocyte co-culture.
Conclusions: Myeloid-specific YAP controls NLRP3-triggered liver inflammation and RIPK3-mediated hepatocyte necroptosis through interaction with HSF1. HSF1

is required for the myeloid YAP-mediated immune regulation in liver IRI. Our findings demonstrate the key mechanistic role of myeloid YAP in liver inflammatory injury, and provide novel therapeutic potential in organ IRI and transplant recipients.

Abstract# 614

Single-cell Rna Sequencing of Latent Murine Cytomegalovirus Infected Lung Transplants

L. A. VanOsdol[1], S. Han[1], M. Kandpul[2], J. J. Wang[1], L. Qiu[3], Z. J. Zhang[1], *[1]Comprehensive Transplant Center, Northwestern University, Chicago, IL, [2]Department of Surgery, Northwestern University, Chicago, IL, [3]School of Medicine, University of California, San Fransisco, San Fransisco, CA*
Purpose: Analyze the transcriptomics of mouse lung cells with and without latent infection of cytomegalovirus (CMV) before and after transplantation and identify key cell types and molecular pathways responsible for CMV reactivation and dissemination.
Methods: Orthotropic left lung transplants were performed using Balb/c recipients and donors with or without latent CMV infection. Lung tissues from transplants and naïve controls were harvested for viral RNA analysis and single cell isolation at day 2 post-transplant. After isolating CD31+ and CD45+ cells using fluorescence-activated cell sorting, single cell suspensions were processed using 10X Genomics for barcoding and cDNA library construction for four different conditions at an average of 15500 cells and 41000 reads per cell. The sequenced data were processed using standard 10X Genomics Cell Ranger pipeline and preliminary analyses were carried out using the Loupe browser where cell clusters were identified using well-accepted surface markers. Pathway analyses were done for bulk differences and for different cell types as defined by markers. Additional transplants were treated with small molecule Myd88 inhibitor to determine whether innate immunity plays a role in transplant induced CMV reactivation.
Results: At 2 days post-transplant, CMV IE-1 mRNA was detected in lung grafts but not in latent lungs not transplanted, suggesting transcriptional activation in the early phase of transplant and ischemia and reperfusion injury as an important contributing factor. Preliminary analysis of clusters show CD31+ lung cells expressing Myd88 increase in number following organ transplant both with and without latent CMV infection. CD31+ lung cells expressing c-Fos are also heightened following transplant. CD11b+ lung cells expressing Myd88 increase in latent CMV infected organs following transplant. CD11b+ lung cells expressing c-Fos were increased following transplantation in CMV infected animals. Pathway analysis of differentiating genes for myeloid cell types shows a number of significant immune response pathways including MIF regulation of innate immunity and communication between innate and adaptive immune cells. Treatment with Myd88 inhibitor decreased the viral DNA copy numbers.
Conclusions: Results indicate an enhanced innate immune response. The heightened expression of c-Fos suggests possible reactivation and dissemination of CMV in transplanted tissue. Pathway analysis of differentiating genes elucidated a number of significant immune response pathways, including both innate response and communication between innate and adaptive immune cells, suggesting reactivation and dissemination of CMV in these cells following transplantation.

Abstract# 615

Galectin-3 Blockade Can Decrease Reperfusion Injury in Response to Ischemia in a Rat Hind Limb Transplant Model

Z. Wang[1], Y. Wang[1], D. Yoeli[1], B. Li[1], A. Su[1], D. Mathes[1], K. Washington[1], E. Farkash[2], C. A. Huang[1], *[1]University of Colorado, Aurora, CO, [2]University of Michigan, Ann Arbor, Ann Arbor, MI*
Purpose: Vascularized composite allograft (VCA) transplant is technically feasible and results in successful clinical outcomes. However, skin and muscle containing VCA is highly susceptible to ischemic injury. Ischemia reperfusion injury (IRI) caused inflammation negatively impacts VCA survival. Galectin-3 (Gal3), an endogenous β-galactoside binding lectin released by macrophages and fibroblasts under hypoxia, can drive inflammation. Here we developed a syngeneic rat hind limb transplant model to reduce IRI and improve VCA transplant outcomes by targeting Gal3.
Methods: Right hind limb of Brown Norway (BN) donor is removed, flushed with heparinized lactated ringers, wrapped in wet gauze and stored at 4 °C for 6 or 24 hours prior to transplant. Recipient animals were provided with either Gal3 blocker, modified citrus pectin (MCP) in drinking water or control untreated water since Day -7. Skin and muscle were obtained at post-operative day (POD) 6 and examined histologically using H&E to quantify injury and inflammation. Serum was collected on POD 6 to measure circulating Gal3.
Results: All transplanted limb grafts exposed to 6 or 24 hours cold ischemia showed dermal and interstitial edema, myocyte necrosis and myofiber disorganization on POD6. In non-MCP recipients, neutrophil and macrophage infiltration was also observed by POD 6 consistent with reperfusion injury. In contrast, in the MCP recipients, inflammation was greatly reduced (Figure 1). ELISA data shows, with 6 hours cold ischemia, Gal3 is 8.17±1.53 ng/ml from MCP recipient and 12.86±1.29 ng/ml from Non-MCP recipient, respectively. With 24 hours cold ischemia, Gal3 is 11.09±1.94 ng/ml (MCP) and 18.64±2.04 ng/ml (Non-MCP). Gal3 is significantly decreased (Figure 2) with MCP treatment.
Conclusions: The syngeneic BN rat hind limb transplant model is a reliable platform to study VCA IRI and evaluate preventative strategies. In this model 6 hours or 24 hours cold ischemia consistently yields extensive inflammation throughout the dermis and endomysium on POD 6. Blocking Gal3 using MCP in drinking water significantly decreases circulating Gal3 and reduces inflammation.

Abstract# 616

Mitochondrial Transplant Minimizes Liver Ischemia Reperfusion Injury in Lean and Obese Mice

C. Watkins[1], G. Lamanilao[1], C. Kuscu[1], C. Kuscu[1], J. F. Pierre[2], J. Eason[1], A. Bajwa[1], *[1]Transplant Research Institute, James D. Eason Transplant Institute, Department of Surgery, The University of Tennessee Health Science Center, Memphis, TN, [2]Department of Pediatrics - Divisions of Neonatology and Pediatric Obesity, The University of Tennessee Health Science Center, Memphis, TN*
Purpose: Ischemia induces altered bioenergetics within cells with increased mitochondrial swelling and reactive oxygen species and that ultimately degrade of cellular function. Ischemia reperfusion injury IRI induces mitochondrial fragmentation resulting in cell death and injury. Additionally, energetically related injuries are worse in metabolically stressed tissues such as steatotic liver, making them more susceptible

to ischemia. Therapeutic interventions that target to improve mitochondrial health to repair, reprogram or replace mitochondria to restore respiratory functions are beneficial for prevention of disease.

Methods: *In Vivo* studies: Liver injury was assessed by serum alanine aminotransferase (ALT; mU/ml) after 60 mins of ischemia and 24 hrs of reperfusion. 20-wk old C57BL/6 (lean and diet induced obese, DIO) mice were i.v. injected with Mitochondria (Mito), isolated from healthy mouse liver (Mito; 50 mcg protein equivalent) 1 day before (-1d) or at time of reperfusion (@R). Along with functional (ALT), histological (H&E) and molecular (RTPCR) analysis were done. *In Vitro* studies: Huh7 and HepG2 human hepatocytes cell lines were used to evaluate uptake and therapeutic use of mitochondria using Seahorse analyzer. Palmitic and Oleic, PA/OA were used to induce lipid accumulation in hepatocytes to mimic steatotic liver. Mitochondria for *in vitro* studies were isolated from human (HEK293) cells.
Results: DIO mice had significantly worse liver function compared to lean mice after IRI (ALT: 4090±236 vs 10308±304, p<0.001). Mito (-1d or @R) treated lean (ALT: -1d, 2288±157; @R, 1548±134, p<0.01) and DIO (ALT: -1d, 6811±656; @R, 2201±183, p<0.001) mice were significantly protected compared to vehicle treated mice after IRI. Mice treated with mitochondria had higher liver gene expression of *Pgc1a* and lower levels of proinflammatory cytokines like (*Tnfa* and *Il1b*) compared to vehicle treated mice. Histology of Mito treated mice had lower Suzuki score. Mito treated cells had significantly higher levels of extra- and intracellular ATP, higher basal oxygen consumption rate (OCR) and spare respiratory capacity measured by seahorse analyzer.
Conclusions: Our data demonstrates that treatment with healthy mitochondria enhances recipient cells energy production to help replace damaged mitochondria by inducing Pgc*1a* to rescue cellular functions. Our current study demonstrates that treatment with healthy mitochondria can be used as therapeutic modality for treatment and/or prevention of liver IRI.

Abstract# 617

Characterization of Kidney Small Extracellular Vesicles Released During Normothermic Machine Perfusion

W. W. Woud[1], A. Arykbaeva[2], D. de Vries[2], I. Alwayn[2], K. Boer[1], C. Baan[1], M. Hoogduijn[1], R. Minnee[3], *[1]Internal Medicine, Nephorology and Transplantation, Erasmus MC, Rotterdam, Netherlands, [2]Department of Surgery, LUMC, Leiden, Netherlands, [3]Department of Surgery, Division of Hepato-Pancreato-Biliary and Transplant Surgery, Erasmus MC, Rotterdam, Netherlands*

Purpose: By characterizing and quantifying the dynamical release of kidney Extracellular Vesicles (EVs) during Normothermic Machine Perfusion (NMP), we aim to gain a better understanding of the value of EVs in 1) kidney quality pre-transplantation and 2) as potential biomarker in recipient's circulation post transplantation.
Methods: Eight discarded Extended Criteria Donor kidneys (6 DCD, 2 DBD, mean warm ischemia times of 12 ± 8 minutes followed by ~13 ± 5 hours of cold ischemia, age 68 ± 7, all male) were perfused in a closed system at 37 ^{0}C for 6 hours. Perfusate samples were taken before and at 1/3/6 hours intervals, stained with a mix of common EV markers (tetraspanins CD9/CD63/CD81) or one of these tetraspanins in combination with either CFSE (enzymatic activity) or HLA-A2. Samples were measured using Imaging Flow Cytometry to identify, quantify and characterize single small EVs (< 300 nm, ssEVs).
Results: CFSE and tetraspanin double-positive ssEVs were quantified at each of the collected time points. We observed a ~700 / 740 / 560 fold increase compared to ssEV levels before perfusion at 1/3/6 hours of NMP, respectively. ssEVs levels were found to be positively correlated with donor age and kidney weight, whilst negative correlations were found for ischemia times. Tetraspanin CD81 was found to represent the majority (~70%) of the excreted ssEVs (CD9: ~15% / CD63 <5%). Furthermore, using HLA-A2 mAbs we were able to discriminate and quantify ssEV populations between NMP samples on the basis of HLA phenotype. Again, the majority of ssEVs expressing HLA-A2 was found to be colocalized with CD81.
Conclusions: During NMP small EVs are excreted and this excretion is highest during the first hour of perfusion. The characterization of excreted small EVs, especially in combination with an HLA phenotype marker, provides a starting point to identify allograft specific EVs and map their clinical implications.

Abstract# 618

Myeloid Yap Signaling is Required for Hepatic Cytoprotection in Liver Ischemia-reperfusion Injury

B. Yang[1], Z. Xue[1], C. Zhang[2], Y. Zhang[2], Y. Liu[2], J. Kupiec-Weglinski[1], H. Ji[1], *[1]Dumont-UCLA Transplant Center, Los Angeles, CA, [2]Dept of Surgery, Zhejiang University, Hangzhou, China*

Purpose: Liver ischemia-reperfusion injury (IRI) is recognized as an innate immunity-driven local inflammation response during hemorrhagic shock, liver resection and transplantation. Yes-associate protein 1 (YAP) is the major downstream effector of hippo pathway.
Methods: This study evaluated the pivotal role of myeloid YAP signaling in a murine model of liver warm IRI.
Results: In our previous study, we found that YAP expression was triggered in human orthotopic liver transplantation (OLT). High post-OLT YAP expression was correlated with well-preserved histology and improved hepatocellular function at post-operative day 1-7. In a mouse model of liver warm ischemia (90min) followed by reperfusion (0-24h), YAP was readily triggered in WT mice after the ischemia insult. Interestingly, unlike in flox control mates, IR stress exacerbated significant liver damage in myeloid YAP deficient mice ($YAP^{M\text{-}KO}$), as evidenced by elevated serum alanine aminotransferase (sALT) level and damaged hepatic architecture. Myeloid YAP deficiency promoted liver IRI deteriorated liver pathology (more severe lobular edema, widespread hemorrhage, and congestion/hepatocellular necrosis), and enhanced hepatic ROS accumulation. On the other hand, compared with YAP-proficient ($YAP^{FL/FL}$) mice, Myeloid specific YAP deficiency exacerbated innate immune responses, as shown by amplified CD68+ macrophages and Ly6G+ neutrophils sequestration in liver IR-livers, and enhanced pro-inflammatory cytokine profile (TNF-α, IL-1β, IFN-β, and CXCL-10).
Conclusions: Our novel findings document the critical role of myeloid YAP signaling in hepatic homeostasis and cytoprotection in liver IRI. Because the enhancement of YAP signaling differentially regulates local innate inflammation and hepatocyte survival, these results provide the rationale for emerging approaches to manage liver IRI in transplant patients.

Abstract# 619

The Inflammatory Response in the Context of Tissue Injury: Roles of Tyro3, Axl, and Mer (TAM) Receptor Tyrosine Kinases in Liver Ischemia/reperfusion Injury

J. Zhang[1], H. Zhang[1], M. Ni[2], R. Busuttil[1], J. Kupiec-Weglinski[1], Y. Zhai[1], *[1]Dumont-UCLA Transplant Center, Los Angeles, CA, [2]Liver Suyrgery, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Purpose: Although the inflammatory response in liver ischemia reperfusion injury has been studied extensively, how the context of tissue injury (presence of necrotic/apoptotic cells) regulates the DAMP-initiated innate immune reaction remains an open question. As macrophages are the dominant innate immune cells in livers and they recognize apoptotic cells mainly by phosphatidylserine (PS)-binding Tyro3-Axl-Mer (TAM) receptor tyrosine kinases (RTKs), we analyze roles of TAM RTKs in liver ischemia/reperfusion injury at both the inflammation activation and resolution stages.
Methods: In a murine liver partial ischemia model (90m), we compared WT and myeloid-specific Axl/MerTK double or single deficient mice in their response to liver IRI (Tyro3 is not expressed in livers). Liver inflammation activation and resolution were evaluated at the peak of liver injury (6-24h) or during the course of tissue repair (3-7 days), respectively.
Results: IR downregulated MerTK, but induced Axl, expression in IR livers at the peak of injury (6-24h). The Axl level was declined, while the MerTK level increased at the resolution of liver IRI (day 3-7 post reperfusion). Compared with WT controls, myeloid Axl/MerTK double or single deficient mice developed significantly more severe liver IRI with enhanced pro-inflammatory activation, as evidenced by elevated sALT levels, worse damaged liver architecture (H/E staining) with higher Suzuki scores, and upregulated pro- but downregulated anti-inflammatory gene expressions in IR livers. Interestingly, liver recovery from IRI was significantly delayed only in Axl/MerTK double and MerTK single KO, but not Axl single KO mice, as documented by histological and molecular analysis of IR livers at day 7 post reperfusion. In vitro, although there were no differences in the response to simple TLR stimulation between WT and Axl/MerTK deficient macrophages (KCs and bone marrow-derived macrophages), the presence of apoptotic cells during inflammatory activation downregulated TNF-a and upregulated IL-10 productions in WT, but not Axl/MerTK deficient, macrophages. Indeed, these TAM RTK deficient macrophages were defective in their abilities of efferocytosis. Furthermore, The regulatory effect of TAM RTKs on inflammatory activation was specific for DAMP- (context of tissue damages), but not PAMP-initiated response, as no differences were found in the zymosan-induced peritoneal inflammatory activation. MerTK only regulated the resolution of zymosan-induced peritonitis

Conclusions: TAM RTKs play critical roles in both the activation and resolution of liver IRI. Both Axl and MerTK regulate the activation, but only MerTK regulates the resolution of liver inflammatory response in IRI. TAM RTKs dampen liver macrophage activation via efferocytosis.

Abstract# 620

Glycogen Synthase Kinase 3 Beta Regulates Distinctive Macrophage Subsets in the Activation and Resolution of Liver Ischemia Reperfusion Injury

H. Zhang[1], M. Ni[2], J. Zhang[1], H. Wang[2], R. Busuttil[1], J. Kupiec-Weglinski[1], Y. Zhai[1], *[1]Dumont-UCLA Transplant Center, Los Angeles, CA, [2]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Purpose: Glycogen synthase kinase 3β (Gsk3β) differentially regulates pro- and anti-inflammatory programs in macrophages upon TLR stimulations. We have documented in a murine liver partial warm ischemia model that both Gsk3 inhibition in WT mice and myeloid Gsk3β deficiency protected livers from IRI. As liver macrophages (MΦs) are heterogenous in their origin and function and the outcome of liver IRI is dependent on not only inflammation activation, but also its resolution, we determined how Gsk3β regulated liver IRI in MΦ-specific and disease stage-specific manner.

Methods: We compared both liver inflammation activation (6-24h) and resolution (3-7d) between WT and myeloid Gsk3β deficient mice. KCs or CD11b+ MΦs were selectively depleted by low-dose clodronate liposomes (CL, 1x 200ul, i.p.,-48h) or by diphtheria toxin (DT, 2x10μg/g, i.v.) in CD11b-DTR mice. WT or Gsk3β deficient KCs or bone marrow-derived MΦs (BMMs) were used to reconstitute CL- or DT-treated hosts.

Results: When KCs were depleted prior to the onset of liver ischemia, the protection of livers from IRI at 6h post reperfusion was abolished in Gsk3β deficient mice. However, livers still recovered from IRI significantly better in these mice, as compared with the WT counterparts. The hepatocellular damages were fully repaired, neutrophils were cleared and infiltrating MΦs were reprogrammed to F4/80+CD11b- KC-like cells in IR livers of the Gsk3β deficient mice at day 7 post reperfusion, while these resolution processes were significantly delayed in WT controls until day 14. To further establish that Gsk3β deficiency in KCs were sufficient to protect livers from IRI, we reconstituted KC-depleted WT hosts (by CLs) with either WT or Gsk3β deficient KCs. Indeed, Gsk3β deficient KCs were much more potent to protect livers: sALT levels were significantly lower with much better preserved liver architectures; liver pro-inflammatory activation was also inhibited more significantly, at 6h post reperfusion. Mechanistically, Gsk3β deficient KCs were protected from necroptotic depletion by IR that significantly higher numbers of Clec4F+ KCs (by immune histochemical staining) were detected in IR livers of Gsk3β deficient vs. WT mice. In vitro analysis of KCs and BMMs revealed that Gsk3β deficiency did not enhance KC efferocytosis, but rather promoted IL-10/inhibited TNF-a induction upon TLR stimulation in both types of MΦs. Importantly, Gsk3β deficiency facilitated the induction of Axl, MerTK and TIM-4 expressions in BMMs upon inflammatory stimulations, which were critical for their reparative functions.

Conclusions: Gsk3β regulates distinctive MΦ subsets at different stages of liver IRI. It promotes KC pro-inflammatory activation, while facilitates infiltrating MΦ reprogramming into reparative type in the resolution of liver IRI.

Abstract# 621

Normothermic-Hyperthermic Machine Perfusion Could Increase Response to Pharmacological Intervention in Mitigation of Liver Steatosis

F. Zhou, M. Xu, G. A. Upadhya, Y. Lin, W. C. Chapman, *Surgery, Washington University in St. Louis, St. Louis, MO*

Purpose: To study the feasibility of mitigating rat liver steatosis with ex-situ normothermic-hyperthermic machine perfusion using a multi-drug 'defatting' combination.

Methods: 16 male Zucker obese rats were randomized into 4 groups: Normothermic (NMP) control, NMP defatting, normothermic-hyperthermic (HMP) control and HMP defatting. Livers were procured and flushed with ice-cold HTK solution, placed in cold storage for less than 2 hours. Perfusate was prepared from rat full blood and buffered with bicarbonate solution under 95% O_2 and 5% CO_2 ventilation, additives include heparin, insulin, cefazolin, bile salt and epoprostenol. Machine perfusion was initiated and maintained at 37°C for 1 hour, after which defatting drugs (GW501516, GW7467, forskolin, hypericin, scoparone, and L-carnitine) were injected and temperature was increased to 40°C until a total course of 4 hours was reached. Perfusate samples were taken at 15min and hourly marks. Liver biopsies were taken before and after machine perfusion. Quantification of steatosis was done by calculating Nile Red relative fluorescence intensity from stained frozen section slides in ImageJ. Statistical analysis was done in GraphPad Prism.

Results: In either NMP or HMP, defatting resulted in significant reduction of Nile Red fluorescence signal (NMP: **p*=0.027, HMP: **p*=0.046). While HMP alone did not show improvement in reducing steatosis (control, HMP vs. NMP: *p*=0.46), defatting drugs yielded increased efficacy under higher perfusion temperature (***p*=0.007, Fig.1A). Nile Red staining images showed similar results (red: Nile Red, blue: DAPI, Fig.1C, scale bar 200μm): Red fluorescence decreased in defatting groups, with HMP being more pronounced, while control groups displayed no noticeable decrease. Additionally, perfusate triglycerides in NMP started increasing after 2 hours, while in HMP such trend was absent (Fig.1B).

Conclusions: This study showed increased efficacy of defatting drugs using normothermic-hyperthermic machine perfusion. While HMP alone increases lipid metabolism, defatting drugs are key to reducing steatosis. This technique might be further improved to optimize for the benefit of accelerated metabolism and lowering the amount of injury and potential drug toxicity under prolonged exposure to hyperthermia.

Abstract# LB 38

Identification and Comprehensive Validation of Prognostic Genes After Ischemic and Reperfusion Injury Across Different Donor Types in Renal Transplantation

D. Zhang, Y. Wang, Y. Wang, X. Hu, *Department of Urology, Beijing Chao-Yang Hospital, Capital Medical University, Beijing, China*

Purpose: Ischemic and reperfusion injury (IRI) remains an inevitable and major challenge for renal transplant patients. The current study aims to obtain overall insights into potential mechanisms and seek prognostic molecular as biomarkers and potential therapeutic targets of IRI for transplantation patients.

Methods: After systematically screened the database, we collected gene expression profiles of over 1000 samples after IRI from eight independent cohorts in the Gene Expression Omnibus (GEO) database. Differentially expressed genes (DEGs) of IRI across different donor types (living donor, cardiac death and brain death) were identified in the discovery cohort of renal transplantation and validated in six independent cohorts including renal, liver and lung transplantations. Additionally, protein-protein interaction (PPI) network and functional enrichment analyses were performed. Then, the above DEGs were further applied to graft survival analysis in a renal transplantation cohort to investigate their prognostic value. Finally, two novel genes of renal IRI were verified in mice renal IRI model using quantitative real-time polymerase chain reaction (qRT-PCR).

Results: Twenty DEGs upregulated after IRI across different donor types and multiple organs were successfully identified and validated. The PPI network showed that these DEGs were strongly connected and enriched in multiple biological processes about transcription and cell cycle. Among DEGs, upregulation of ten genes was found to be associated with poor long-term kidney allograft survival. Finally, two novel prognostic genes were successfully verified by qRT-PCR in the mice renal IRI model.

Conclusions: We successfully identified and validated twenty IRI-associated genes throughout different donor types and transplant organs. Besides, ten of them were significantly associated with renal graft survival, which offered promising and novel therapeutic targets for transplantation patients to treat IRI.

Abstract# 622

Donor-derived Cell-free DNA in Upper Extremity Vascular Composite Allograft Recipients

R. Kalsi[1], M. Abuzeineh[2], J. Littleton[1], J. T. Shores[1], D. S. Cooney[1], C. Cooney[1], R. J. Redett[1], G. Brandacher[1], D. C. Brennan[2], *[1]Plastic and Reconstructive Surgery, Johns Hopkins University, Baltimore, MD, [2]Nephrology, Johns Hopkins University, Baltimore, MD*

Purpose: Diagnosing rejection in VCA recipients relies on clinical exam and biopsy which are both easily confounded by common causes of skin irritation. dd-cfDNA in recipient plasma originating from injured or apoptotic donor allograft cells is a proven non-invasive indicator of allograft rejection in renal transplant recipients but has not been evaluated in VCA recipients.

Methods: VCA patients presenting for evaluation at the outpatient plastic surgery clinic during periods of graft stability without clinical or histologic evidence of rejection, and/or during episodes of suspected clinical and/or biopsy proven rejection were included in this study. dd-cfDNA levels were collected prospectively at each visit with two commercially available kits. Based on established values in renal transplant, a dd-cfDNA level > 1% was considered suggestive of a rejection event.

Results: 5 VCA recipients (3 bilateral and 1 unilateral upper limb, 1 lower abdominal wall, penis, and scrotum) were enrolled in this study. One patient had no clinical or biopsy evidence of rejection with dd-cfDNA level <1% and 1 patient had dd-cfDNA levels >4% at three time points surrounding an episode of biopsy proven BANFF CTA 2007 Grade III rejection. 1 patient with a stable graft and no clinical concern for rejection had a routine dd-cfDNA level >1%. A final patient with non-specific skin changes but biopsy evidence of severe acute cell mediated rejection had dd-cfDNA level <1%.

Conclusions: These data reflect the first attempt to characterize dd-cfDNA in human upper extremity VCA recipients. Although these early results are conflicting, larger cohorts with careful correlation with biopsy findings are needed to fully characterize dd-cfDNA level trends in extremity VCA recipients.

Abstract# 623

General Public Attitude Toward Vascularized Composite Allografts (VCA) Donation?

M. S. S Gharibdousti[1], M. T Khasawneh[1], A. L Friedman[2], *[1]System Science and Industrial Engineering, Binghamton University, Vestal, NY, [2]LiveOnNY, New York City, NY*

Purpose: To analyze factors associated with affirmative authorization for VCA donation from public opinion.

Methods: KnowledgePanel is the largest online panel that relies on probability-based sampling techniques for recruitment. This panel provides samples with the highest level of representativeness available in online research for the measurement of public opinions, attitudes, and behaviors. For the selection of general population samples from KnowledgePanel, a patented methodology has been developed that ensures all samples behave as the equal probability selection method (EPSEM) samples. This methodology starts by weighting the pool of active members to the geodemographic benchmarks. Using the resulting weights as measures of size, a probability-proportional-to-size (PPS) procedure is used to select study-specific samples. The geodemographic benchmarks used to weight the active panel members for computation of size measures include: gender, age, race, education, census region, household income, homeownership status, metropolitan area, and Hispanic origin.

Results: A total of (n = 260) responded to the survey that included eight sections; Demographics, Familiarity with Donation, Face and Hand Donation, Consent, Reasons, Medical Trust/Distrust and Funeral Plans. After answering these questions, the respondents were exposed to a stimulus that tells the story of a fire fighter who received a face transplant and his subsequent life. Respondents then answered stimulus questions (4 questions) to determine whether the stimulus affected their responses about face and hand donation. At the end, three In-Depth questions are asked. After data collection and analysis, we tested the significance among different groups of respondents. Our results show that after reading the stimulus, there is a significance difference in respondents' willingness to register and to consent for face and hand donation for themselves and their family members. In addition, there is a significant difference in the participants' willingness to register for face and hand donation. This significance is observed among different age groups, between both genders, among participants with income more than or less than 50k, and among different ethnic groups. Other influential factors are region, religious, spirituality, belief in God and military background.

Conclusions: This comprehensive survey provided profound insights into the factors associated with organ donation, and the likely authorization for VCA donation. The favorable response rate after reading the stimulus story emphasizes the importance of awareness and familiarity with the issue of face and hand donation. Touching the impact this transplant would make in one's quality of life is another contributing factor in increasing the registration and consent rate for donation. This study is funded by the Department of Defense (W81XWH-17-1-0646).

Abstract# LB 40

Determining Endpoint Criteria in Ex Vivo Normothermic Limb Perfusion (EVNLP)

S. K. Pandey[1], A. Meyers[1], P. Sadeghi[1], V. Kopparthy[1], T. Xia[1], H. Brunengraber[2], S. Dasarathy[3], A. Rampazzo[1], B. Bassiri Gharb[1], *[1]Plastic Surgery, Cleveland Clinic, Cleveland, OH, [2]Department of Nutrition, School of Medicine, Case Western Reserve University, Cleveland, OH, [3]Department of Gastroenterology, Cleveland Clinic, Cleveland, OH*

Purpose: There are no established criteria for discontinuing EVNLP before irreversible muscle and endothelial cell damage occur. This study aimed to evaluate weight gain as a real-time clinical indicator of injury during EVNLP

Methods: Sixteen forelimbs were procured from Yorkshire pigs and preserved using EVNLP (37°C) (n=8) or static cold storage (SCS 4°C) (n=8). An oxygenated perfusate containing oxygen carrier HBOC-201 was used. EVNLP continued for 24 hours or until systolic perfusate pressure was ≥115 mmHg, fullness of compartments or a reduction of tissue oxygen saturation by 20% were observed. Limb weight, contractility, hemodynamic parameters, perfusate electrolytes, metabolites and gases

were recorded and analysed. Biopsies of biceps muscles were collected 6 hourly, and muscle injury scores (MIS) calculated. Outcomes were compared at 2%, 5%, 10%, and 20% limb weight gain. Pearson's correlation between parameters, t-test or ANOVA followed by Tukey post hoc pairwise comparisons were performed.
Results: EVNLP lasted 20±3 hours. Weight gain was observed after 13±5 h (2%), 15±6 h (5%), 16±6 h (10%), and 19±4 h (20%). Weight gain correlated positively with MIS ($r=0.92$, $p<0.01$), perfusate potassium ($r=0.81$, $p<0.01$) and mean perfusate pressure ($r=0.63$, $p<0.01$). Weight correlated negatively with contractility ($r=-0.71$, $p<0.01$). At 5% weight gain, significantly higher MIS ($p<0.01$), perfusate potassium ($p=0.03$), and lactate ($p=0.02$) were recorded compared to the baseline. Mean MIS at 5% weight gain was not significantly different from SCS limbs at 6 hours ($p=0.07$). Arterial resistance increased over time ($r=0.55$, $p<0.05$) and at 20% weight gain was significantly higher ($p=0.02$) than at 5% weight gain, the latter being not significantly different from baseline ($p=0.28$). No significant difference was observed between glucose consumption ($p=0.48$), oxygen uptake rate ($p=0.94$) or creatine kinase ($p=0.30$) at the different weight levels. Median muscle contractility was 4 (1-5) at 5% weight gain, which decreased to 3 (0-4) and 2 (0-2) at 10% ($p=0.32$) and 20% ($p=0.24$), respectively.
Conclusions: Weight gain precedes increasing arterial resistance. Muscle injury in limbs at 5% weight gain is similar to that of limbs preserved at 4°C for 6 h (standard cold ischemia time) and therefore 5% weight increase may serve as a criterion for discontinuation of EVNLP.

Abstract# LB 41

Efficacy of Ex Vivo Normothermic Limb Perfusion in Maintaining Cellular Viability and Muscle Function

T. Xia[1], P. Sadeghi[2], V. Kopparthy[2], S. Pandey[2], A. Rampazzo[2], B. Bassiri Gharb[2], *[1]School of Medicine, Case Western Reserve University, Cleveland, OH, [2]Department of Plastic Surgery, Cleveland Clinic, Cleveland, OH*

Purpose: The purpose of this study was to evaluate cellular injury and myocyte function of amputated limbs following ex vivo normothermic limb perfusion (EVNLP) compared to traditional cold storage.
Methods: Twenty human upper extremities were procured from organ donors after brain death. Ten were perfused with an oxygenated colloid solution containing packed red blood cells at 38°C for 48 hours or until the termination criteria were met (maximum arterial pressure >115 mmHg, weight increase >20%, compartment pressure >30 mmHg, tissue oxygen saturation decrease >20%). Electrolyte derangements were managed with partial perfusate exchanges every 3 hours beginning at hour 6 of perfusion. Contralateral upper limbs (controls) were preserved at 4°C. Limb viability was assessed through contractility testing, tissue oxygen saturation, infrared thermography, and indocyanine green (ICG) angiography. H&E and caspase-3 staining were performed. Myocyte injury scores (MIS) and caspase-3 positivity were assessed using the Aperio ImageScope software by two investigators blinded to the experimental group and time. Myocytes were classified as damaged if there was nuclei extravasation, disrupted cell membrane, or distinct fissures within the cytoplasm. Statistical analysis was performed with Kruskal-Wallis and paired t-test.
Results: Limbs were perfused for 41.6 ± 9.4 hours. For the EVNLP limbs, contractility was observed for a median of 30.5 hours (range 16-40 hours), and maximum contractility was maintained for a median of 8 hours (range 1-15 hours). Control limbs had a contractility score of 0 after procurement. The final weight change was +0.4 ± 12.2% and 0 ± 0% in the EVNLP group and control group, respectively. One limb developed compartment syndrome after 6 hours. Thermography and ICG angiography demonstrated uniform peripheral perfusion of the experimental limbs throughout. Average MIS was 24.7 ± 13.0% and 44.3 ± 30.6% for the EVNLP and control groups, respectively. In the EVNLP group, MIS did not significantly differ among time-points 0, 12, 24, 36, and 48 hours ($p=0.46$). In the control group, MIS was significantly higher at end time-points (mean = 44.8 ± 4.8 hours) compared to time-point 0 ($p=0.009$).
Conclusions: In contrast to hypothermic preservation, EVNLP can halt the progression of myocyte injury for up to 48 hours and maintain normal muscle function beyond 24 hours.

Abstract# LB 42

Tissue Specific Antigen-presentation in VCA Transplantation

B. Kern[1], J. Mengwasser[1], A. Reutzel-Selke[1], M. I. Ashraf[1], D. Polenz[1], K. Fuehrer[1], S. Lippert[1], P. Tang[1], F. Martin[1], C. Witzel[1], I. M. Sauer[1], J. Pratschke[1], S. G. Tullius[2], *[1]Dept. of Surgery, Charité Campus CCM|CVK, Universitaetsmedizin Berlin, Germany, Berlin, Germany, [2]Division of Transplant Surgery and Transplant Surgery Research Laboratory, Brigham and Women's Hospital, Harvard Medical School, Boston, MA*

Purpose: Vascular Composite Tissue Allotransplantation (VCA) has become a clinical reality. High frequencies of acute rejections remain an unsolved problem. Here, we delineated components of VCA for their contribution to graft immunogenicity, antigen presentation and early immune responses.
Methods: Early immune responses following skin and orthotopic hind limb (HL) Tx in allogeneic mouse models dissected the role of antigen presenting cells (APC) with a focus on classical dendritic cells (DC). Using standard depletion protocols, grafts of zDC-DTR (diphteria toxin receptor) transgenic and C57BL/6 wild type (WT) mice, pretreated with DT or clodronate liposomes (CL) for APC/DC depletion, respectively (CL), were transplanted into DBA2 recipients. Grafts from untreated WT mice served as controls. Immune cell phenotyping was performed by flow cytometry in blood, spleen and lymph nodes (LN) of recipients. Intragraft gene expression of relevant cytokines was analyzed by qPCR, serum cytokine levels by Luminex assays. Rejections were assessed serially (POD 1,3,5) based on the BANFF criteria (hair loss, erythema, edema, desquamation, mummification, grading 0-4).
Results: Both, WT hindlimb and skin grafts showed increased signs of acute rejection by POD 5 (grade 3) compared to DC-depleted HL groups (grade 2). DC counts ($CD11c^+$, $CD11c^+MHCII^+/CD40^+$) were markedly increased in recipients of skin WT grafts compared to HL WT grafts (blood, spleen, LN, POD6, $p<0.0001$). Depletion of donor DC or APC significantly reduced DC counts in skin graft recipients ($p<0.05$ vs. WT), but had no impact on DC numbers following HL Tx. Recipients of HL grafts showed significantly higher cDC1 subset counts ($CD11b^-B220^-CD11c^+CD8^+$) compared to skin Tx (blood, spleen, LN, $p<0.05$); cDC2 subset counts ($CD11b^+CD11c^{high}MHCII^{high}$) were significantly increased in recipients of skin grafts ($p<0.01$). Numbers of $CD4^+IL17A^+$ T cells were augmented significantly following skin Tx ($p<0.0001$ vs. HL) while IL-6, TNF-α, IL-17, and TNF-β protein levels were elevated in WT recipients of HL grafts ($p<0.05$ vs. skin Tx).
Conclusions: Early immune responses including DC activation differed significantly between skin and hindlimb transplant recipients. Focusing on DC and Th17 immune responses may provide specific therapeutic targets in VCA transplantation.

Abstract# 624

Cardiac Outcomes in Isolated Heart and Simultaneous Kidney and Heart Transplants in the US

K. A. Agarwal[1], H. Patel[1], N. Agrawal[1], F. Cardarelli[1], N. Goyal[2], *[1]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA, [2]Nephrology, Tufts Medical Center, Boston, MA*

Purpose: Kidney dysfunction is not uncommon in patients with advanced heart failure. Simultaneous kidney and heart transplants (SKHT) have gained acceptance as treatment for patients with end-stage heart failure (ESHF) and severe kidney dysfunction. US saw a rise of 650% in SKHT from 2000 to 2019. Despite increasing number of SKHT, the selection criteria remain poorly defined and vary across transplant centers. We wanted to identify heart transplant candidates who may benefit from a simultaneous kidney-heart transplant.
Methods: In this retrospective cohort study, we examined the patient and cardiac allograft survival for SKHT and heart transplant alone (HTA) recipients between 1987 and 2019 using the United Network for Organ Sharing (UNOS) database. We then performed a subgroup analysis in recipients with post-transplant Acute Kidney Injury (AKI) requiring renal replacement therapy (RRT) and compared outcomes between SKHT and HTA recipients.

Results: A total of 61,410 HTA and 1,507 SKHT recipients were included in the final analysis. While patient survival was comparable between SKHT and HTA groups (12.4 vs. 11.3 years), pretransplant dialysis-dependent patients derived a significant survival benefit from SKHT (12.4 years vs. 9.9 years). Cardiac graft survival was better in SKHT (12.5 vs. 11.2 years). Age less than 30 years (OR 1.27), higher BMI (OR 1.02), reduced GFR (OR 9.46 for GFR<30, OR 2.68 for 30-44, OR 1.99 for GFR 45-59), mechanical cardiac support (OR 1.28), recipient diabetes (OR 1.15), inotropic support (OR 1.11) and prior sternotomy (OR 1.61) were significant risk factors for AKI requiring dialysis post-transplant. Among these patients, SKHT recipients had a significantly better survival as compared to HTA recipients (11.9 vs. 2.7 years).
Conclusions: Our data supports consideration of SKHT in dialysis-dependent heart transplant candidates and suggests that patients who are at increased risk of requiring RRT post heart transplant may also benefit from SKHT.

Abstract# 625

Nrf2 Assessment in Discarded Liver Allografts: A Role in Allograft Function and Salvage

O. Ahmed, M. Xu, F. Zhou, A. N. Wein, G. Upadhya, Y. Lin, W. Chapman,
Surgery, Washington University School of Medicine, Saint Louis, MO
Purpose: With mounting pressures to optimize organ availability for transplantation, there is a focus on reducing organ discard and attempting to resuscitate declined grafts for later use. The nuclear factor erythroid 2-related factor-2 (Nrf2) axis may be an important mediator in allograft function. This study aimed to determine the functional expression and clinical relevance of Nrf2 in discarded human livers.
Methods: Biopsies from 40 discarded liver allografts were studied. Nrf2 expression was quantified by immunoblotting and patients were stratified into a high Nrf2 and low Nrf2 group. Relevant donor clinical and biochemical data were compiled. The modified Suzuki scoring system and Banff criteria were used for histological grading of hepatic injury. Inflammatory infiltration was quantified by immunofluorescence for CD3-positive cells. Allografts (n = 8) were exposed to 6 hours of normothermic machine perfusion (NMP). Liver function (LFT) and lactate clearance were recorded pre- and post NMP to determine viability. Advanced CellSens and GraphPad software were used for biostatistical analysis.
Results: Livers with greater Nrf2 levels demonstrated lower ALT (mean 53 IU/L vs 152 IU/L, p = 0.049) and AST (58 IU/L vs 220 IU/L, p =0.045) prior to organ procurement (Figure 1A). Serum glucose (mean 171 mg/dL vs 126 mg/dL, p = 0.046) (Figure 1B) and hepatic glycogen content were both higher in the low Nrf2 group. Greater vascular endothelial inflammation (Figure 1C) around the hepatic artery (p = 0.01) and portal vein (p = 0.003) was observed in livers with lower Nrf2 expression and these organs also demonstrated increased periportal CD3 infiltration (p < 0.01) (Figure 1D). Following 6 hours of NMP, livers with higher Nrf2 expression demonstrated lower LFT derangements (ALT 5919 IU/L vs 12000 IU/L; AST 7817 vs 33405 IU/L) and healthier lactate clearance (0.5 mmol/L vs 2.98mmol/L) compared to allografts with lower Nrf2 expression (p < 0.05) (Figure 1E).
Conclusions: This study highlighted the association of a rich Nrf2 environment with more favourable clinical parameters and its potential impact on the functionality of discarded liver allografts. Nrf2 expression may act as a useful marker to differentiate between salvageable discarded allografts and targeting the Nrf2 axis could have a rationale in future studies.

Abstract# 626

Biomarkers of Kidney Injury and Repair in Expanded-Criteria Deceased Donor Kidney Transplant Recipients: A Prospective Study

A. Al Jurdi[1], O. Efe[1], B. Aoyama[2], M. Lima[2], H. Silva[2], I. Schmidt[3], S. Waikar[3], V. Sabbisetti[4], L. V. Riella[1], *[1]Center for Transplantation Sciences, Massachusetts General Hospital, Charlestown, MA, [2]Escola Paulista de Medicina, UNIFESP, São Paulo, Brazil, [3]Boston Medical Center, Boston, MA, [4]Brigham and Women's Hospital, Boston, MA*
Purpose: Expanded-criteria donor (ECD) kidney transplants are at higher risk of kidney injury. Biomarkers that better predict short and long-term outcomes in ECD kidney transplant recipients are needed.
Methods: In this prospective study, we evaluated the prognostic value of seven biomarkers of kidney injury (KIM-1, SuPAR), repair (MCP-1, YKL-40) and inflammation (MCP-1, TNFR1, TNFR2 and CXCL9) in 50 ECD kidney transplant recipients at a single center. Blood samples were collected on days 0, 7, 30, 90, 180 and 360 after transplantation (Fig. 1A). Plasma biomarker levels were measured using a Meso Scale Discovery platform. Biomarker tertiles and mean estimated glomerular filtration rate (eGFR) of different groups were compared using one-way analysis of variance (ANOVA). Linear and logistic regression analyses of biomarkers were performed to assess their predictivity of allograft outcomes.
Results: The median age of recipients was 51 years, 74% were male, and the most common etiology of end-stage kidney disease was diabetic nephropathy. One-year patient and allograft survival were both 100%. Five patients developed biopsy-proven acute rejection. Higher day 7 tertiles of KIM-1, SuPAR, TNFR1 and TNFR2 were associated with lower eGFR at days 7 and 30 but not at day 360 (Fig. 1B). Combining day 30 eGFR and change in biomarker levels from day 7-30, we developed a multivariate logistic regression model that was able to predict stability vs. decline in eGFR from day 30-360 with an area under the receiver operating characteristic (ROC) curve of 0.85 (Fig. 1C).
Conclusions: Single biomarker values provide a cross-sectional view of allograft status but have limited predictive value for allograft outcomes. Changes in biomarker levels over time can give a more dynamic picture of allograft status and better predict one-year outcomes.

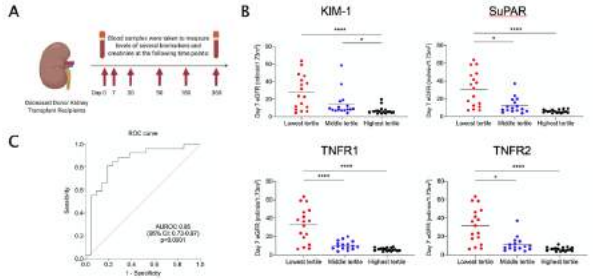

Figure 1. Longitudinal kidney biomarker levels post-transplantation. (A) Study design. (B) Analyses of biomarker levels at day 7 according to tertiles and eGFR for 50 ECD kidney transplant recipients. Differences assessed by one-way ANOVA followed by Bonferroni correction. (C) ROC curve for logistic regression model using changes in biomarker levels from day 7-30 to predict stable vs. decline in eGFR from day 30-360.

Abstract# 627

Remote Monitoring Using Mobile Phlebotomy and Donor-derived Cell-free DNA in Kidney Transplant Recipients During the Covid-19 Pandemic

N. Ali[1], J. Miles[2], V. Tatapudi[1], R. Montgomery[1], *[1]NYU Langone, New York, NY, [2]Medical Science Liason, CareDx, Brisbane, CA*
Purpose: The rapid shift to telemedicine and remote monitoring of kidney transplant recipients (KTRs) during COVID-19 aimed to mitigate exposure risk for this vulnerable population. dd-cfDNA (AlloSure, CareDx Brisbane) is a well-established biomarker for surveillance of KTRs and is associated with allograft tissue injury, including immunological events such as acute rejection. Here we describe an innovative approach to remote surveillance for KTRs using mobile home phlebotomy during the pandemic.
Methods: Pilot program of KTRs enrolled into the mobile home phlebotomy (RemoTraC) from March - November 2020. AlloSure dd-cfDNA was concomitantly performed with routine post-transplant laboratory studies at regular time intervals as per standard of care.
Results: 159 KTRs were enrolled in the mobile phlebotomy program with 1421 draws completed during the surveillance period. Patient demographics are sum-

marized in Table 1. The median AlloSure dd-cfDNA level was 0.21% (IQR 0.12 - 0.42%). 25 for-cause biopsies were performed in patients monitored with mobile phlebotomy. 12 patients had biopsy proven rejections paired with AlloSure dd-cfDNA (1 borderline, 2 TCMR1A, 4 TCMR2A, 2 TCMR1B, 2 chronic active TCMR and 1 mixed AMR/TCMR). The median AlloSure dd-cfDNA was 0.5% (IQR 0.2-3.26%) in patients with active rejection compared to 0.14% (IQR 0.12-0.56%) in patients with no rejection (p=0.03). There was no difference in serum creatinine between the two groups (p=0.3). The median AlloSure dd-cfDNA levels in TCMR2A/1B and mixed AMR/TCR were 0.72 and 7.7% respectively.

Conclusions: AlloSure dd-cfDNA can optimize post-transplant care by identifying patients at risk of allograft injury and rejection. This analysis demonstrates the feasibility of mobile phlebotomy for routine surveillance in combination with telehealth strategies during the unprecedented COVID-19 pandemic. In addition, utilization of dd-cfDNA helped clinicians direct limited resources during the pandemic for allograft biopsies when paired with standard clinical markers such as creatinine.

Table 1: Patient demographics.

Abstract# 628

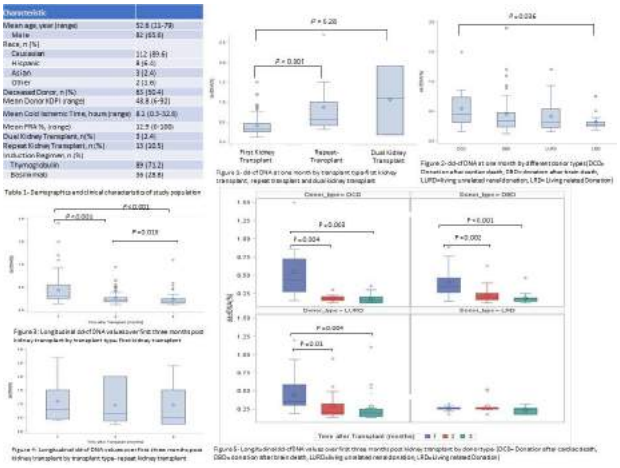
Longitudinal Variance of Donor Derived Cell Free DNA (dd-cf DNA) in Stable Kidney Transplant (Tx) Patients are Influenced by Donor/ Recipient Variables

S. Anand, F. Lopez-Verdugo, J. Sanchez-Garcia, L. Dong, M. Fife, J. Krong, D. Morris, T. Srinivas, *Intermountain Medical Center, Murray, UT*

Purpose: The limits and cut offs of dd-cfDNA as an injury biomarker in kidney transplant (KTx) are based on coupled single event (biopsy) measurements. It represents an oversimplification that extrapolates from a single measurement to prospective repeat measures. Meaningful interpretation of repeat measures of dd-cfDNA demands : 1) factors determining biologic variability; 2) time variance of dd-cfDNA levels post-Tx; and 3) relationship to donor and recipient characteristics. We hypothesized that incorporating knowledge of the above factors would refine the clinical utility of the use of dd-cfDNA as an injury biomarker by better selection of patients for further intervention.

Methods: After excluding patients with biopsy proven acute rejection, a total of 125 patients who underwent kidney transplantation between 1st June 2016 to 31st December 2019 had serial dd-cfDNA samples obtained at months 1, 2, 3, 4, 6, 9 and 12 post-transplant as part of their standard of care.

Results: 82 (65.6%) participants were male, with a mean age of 52.6 (Table 1). Median dd-cfDNA at 1 month post-Tx was higher in repeat KTx (0.57%, $p < 0.001$), and dual KTx (1.10%, $p = 0.28$) versus a single KTx (0.31%) (Fig 1). A decreasing and significant trend was observed in median dd-cfDNA at 1 month post-Tx for patients receiving a kidney from donor after cardiac death (DCD [0.45%]), donor after brain death (DBD [0.37%]), living unrelated (LURD [0.34%]) or living related (LRD [0.27%]) donors (p=0.036)(Fig 2). Longitudinal, repeated dd-cfDNA measurements showed a significant decrease over time during the first three months after transplantation for first KTx (p<0.001) (Fig 3). For re-Tx (n=7), there was a non-significant downtrend of dd-cfDNA over time (Fig 4). Sub-group analysis, by donor-type, showed a significant downtrend in dd-cfDNA values recipients with DCD, DBD, LUKT showed from one month to three months (p<0.05) (Fig 5). Panel-reactive antibodies (PRA) were positively correlated with dd-cfDNA ($R2 = 0.113$, $p < 0.001$).



Conclusions: Repeat Tx, Dual Tx and higher PRA are associated with a higher dd-cfDNA likely a function of the size of the dd-DNA source. Values of dd-cf DNA at one month are likely higher at baseline, attributable to initial ischemia reperfusion injury. dd-cfDNA should be interpreted with caution in certain donor types (DCD, DBD, LUKT). Incorporation of donor/recipient variables and time down dependent evolution post transplant is material for rational interpretation of ddcfDNA cutoffs in clinical decision making.

Abstract# 629

Longitudinal Surveillance, Relative Change Value (RCV) Improve Diagnostic Test Accuracy (DTA) of Donor-Derived Cell Free DNA (dd-cfDNA)

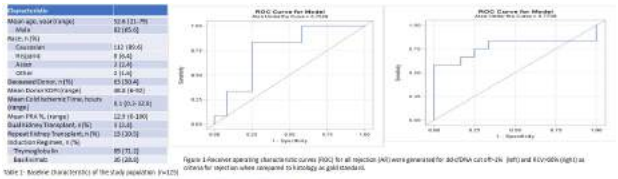
S. Anand, F. Lopez-Verdugo, J. Sanchez-Garcia, L. Dong, M. Fife, J. Krong, D. Morris, T. Srinivas, *Intermountain Medical Center, Murray, UT*

Purpose: dd-cfDNA, an injury biomarker in kidney transplant (KTx), is emerging as a trigger for biopsy (Bx) and superior to the traditional trigger of change in renal function. This is based on single event/Bx bracketing measurement of dd-cfDNA.

Rational interpretation of serial dd-cfDNA, as an injury biomarker demands assessment of variability (intra- and Interindividual) and RCV of dd-cfDNA. We hypothesized that incorporating RCV vs. single cutoff value improves DTA of dd-cfDNA for rejection.

Methods: After excluding patients with biopsy proven acute rejection and CMV/BK viremia, patients with serial dd-cfDNA at 1,2,3,4, 6, 9, 12-months post Tx were included. We computed the intra-individual change value(CVI), inter-individual or group change value (CVG), from dd-cfDNA values with more than or equal to 3 sequential results within the first 12 months of renal transplant. We also calculated index of individuality (II) as the CVI/CVG ratio and the relative change value (RCV). RCV is defined as the difference that must be exceeded between 2 sequential results for a significant change to occur. In a subset analysis of 24 patients with rejection, receiver operating characteristic curves (ROC) for all rejection (AR) were generated for dd-cfDNA cut off>1% and RCV>66% as criteria for rejection when compared to histology as gold standard.

Results: Of 125 patients, 82 (65.6%) participants were male, with a mean age of 52.6 (Table 1).CVI was 34.7%, CVG was 93.2%., II was calculated at 0.37, and RCV was 98% (Table 2). After excluding one month values, due to largely higher values at one month in part of ischemia reperfusion injury, RCV changed to 66%. For dd-cfDNA>1%, discrimination for all rejection (AR), AUC was 0.7569 versus 0.7708 when compared to RCV >66% as criteria (Fig 1). Utilizing RCV as a criteria resulted in increase of 28% and 21% for positive predictive value (PPV) and negative predictive value (NPV) respectively (Table 3).



Conclusions: 1) Our study reports performance of RCV in 'real world' stable KTx population outside of a clinical trial. 2) An RCV of 66% in 'real world' Ktx population is similar to clinical trial results of 61%. We propose:1) Longitudinal surveillance of dd-cfDNA and RCV should supplant a single cutoff value for dd-cfDNA at biopsy 2) Clinical decision making using dd-cfDNA should be personalized at the patient level, taking into account both baseline values and longitudinal intra-individual trends.

Abstract# 630

Evaluation of Meningococcal Vaccine Response Among Solid Organ Transplant Recipients Receiving Eculizumab

R. Arora[1], C. Kane[1], K. Cunningham[1], M. Ison[2], *[1]Pharmacy, Northwestern Memorial Hospital, Chicago, IL, [2]Divisions of Infectious Diseases and Organ Transplantation, Northwestern Memorial Hospital, Chicago, IL*

Purpose: Patients receiving eculizumab are at a 1,000-2,000-fold increased risk of invasive meningococcal infections. Therefore, the Advisory Committee for Immunization Practices recommends that these patients receive meningococcal vaccination at least 2 weeks prior to the start of therapy. However, despite adequate vaccination, multiple reports of breakthrough meningococcal disease have been reported. Solid organ transplant (SOT) recipients are a unique population with notoriously diminished vaccine response due to chronic immunosuppression, potentially placing them at increased risk for breakthrough meningococcal disease while receiving eculizumab. Therefore, the purpose of this study is to evaluate meningococcal vaccine response in this patient population.

Methods: This is a single-center, retrospective evaluation of all solid organ transplant recipients 18 years of age or older that underwent eculizumab therapy between January 1, 2014 and June 1, 2020. All patients that received both doses of the meningococcal vaccines and had subsequent N. *meningitidis* IgG concentrations available within 6 months of vaccination were included. The primary outcome was the meningococcal vaccine response rate, which was measured using N. *meningitidis* IgG concentrations against serogroups A, C, Y, and W-135.

Results: A total of 17 patients met the pre-specified inclusion criteria and was primarily composed of lung transplant recipients. Preliminary results indicated that N. *meningitidis* IgG serologic response occurred in only 41.2% of patients against serogroup A, 58.8% against serogroup C, 47.0% against group Y, and 70.6% to serogroup W-135 following vaccination. Further results to follow.

Conclusions: Meningococcal IgG vaccine response varied against the different meningococcal serogroups. Consideration should be given towards repeat vaccination and prolonged antimicrobial prophylaxis in vaccine non-responders undergoing eculizumab therapy.

Abstract# 631

Single Center Experience Comparing Two Clinically Available Donor Derived Cell Free DNA Tests

S. Bunnapradist[1], S. Lee[2], P. Homkrailas[3], G. Danovitch[3], *[1]UCLA, Los Angeles, CA, [2]Pharmacy, David Geffen School of Medicine at UCLA, Los Angeles, CA, [3]David Geffen School of Medicine at UCLA, Los Angeles, CA*

Purpose: Donor derived cell-free DNA (dd cf-DNA), this new technology allows for non-invasive monitoring of graft function. Two most commonly used assays are Prospera (Natera®, San Carlos, California) and AlloSure (CareDx®, Brisbane, California). We report our experience in comparing simultaneous use of these tests.

Methods: A series of 15 paired-samples from individual kidney transplant recipients using Prospera and AlloSure test were included. We used the company cut off of >1% to indicate active rejection for Prospera, and 0.5% or 1% for Allosure. Acute rejections were all defined by kidney histology.

Results: The paired-results are shown in Table 1. There were concordant results for all 15 paired-samples when using Allosure cut off level of 0.5%. A single discordant result was observed when using Allosure cut off level of 1%. Kidney biopsies were performed in seven of the cases where dd cf-DNA was elevated. Rejection was found in six of biopsy results (see in table 2). When cut off level of 1% was used, Prospera identified 80% (4/5) of T-cell mediated rejections (TCMR) compared to 60% for Allosure (3/5). Both assays recognized the single case of antibody mediated rejection. When using cut off level of 0.5% for Allosure, all 6/6 rejections were identified.

Conclusions: There were concordant results between the two using cut off of 1% for Prospera and 0.5% for Allosure. The accuracy of the result was confirmed by the kidney biopsy (5 active rejection diagnosis + 1 non-rejection). Prospective, head-to-head trials are needed to compare the accuracy and predictive values of these two clinically available dd-cfDNA assays.

Table 1 Comparing between 2 donor derived cell free DNA test results

Patients	Prospera results	Allosure results
1	0.08%	0.15%
2	0.26%	0.22%
3	0.25%	0.23%
4	0.65%	0.57%
5	0.90%	0.62%
6	2.06%	0.98%
7	2.55%	2.10%
8	4.72%	3.60%
9	4.40%	3.70%
10	4.47%	3.80%
11	7.56%	4.80%
12	<0.08%	0.16%
13	<0.08%	<0.12%
14	<0.08%	<0.12%
15	0.28%	<0.26%

Table 2 Donor derived cell free DNA levels and kidney biopsy results

Prospera results		Allosure results			Kidney biopsy results
Levels	Cut off level 1%	Levels	Cut off level 1%	Cut off level 0.5%	
0.90%	Negative	0.62%	Negative	Positive	TCMR IA
2.06%	Positive	0.98%	Negative	Positive	TCMR IA
2.55%	Positive	2.10%	Positive	Positive	ABMR
4.72%	Positive	3.60%	Positive	Positive	TCMR IIB
4.40%	Positive	3.70%	Positive	Positive	Suspicious for TCMR
4.47%	Positive	3.80%	Positive	Positive	TCMR IB

Abstract# 632

Comparative Proteomics Analysis Identifies the Biomarker of Ischemia-Reperfusion Injury During Liver Transplantation

M. Chen[1], L. Xiaohong[2], H. Xitao[1], J. Weiqiang[1], *[1]Transplant Center, Sun Yat-sen University, Guangzhou, China, [2]Sun Yat-sen University, Guangzhou, China*

Purpose: To a large extent the success of liver transplantation depends on quality of allografts. The molecular basis of the susceptibility of different liver allografts to transplant injury remains undefined. We investigated the proteomic alterations in liver grafts of different qualities by isobaric Tags for Relative and Absolute Quantification (iTRAQ).

Methods: Transplanted liver samples were collected and divided into three groups: the optimal graft (OG) group, early allograft dysfunction (EAD) group, and primary nonfunction (PNF) group. Comparative quantitative proteomic analysis and multiple reaction monitoring (MRM) verification was performed. Samples from human IRI model were collected for further investigation at three different time points during liver transplantation.

Results: A total of 6505 proteins were preliminarily identified in human liver. Specific proteins associated with IRI were identified by comparing the 3 groups at three different time points. In the IRI phase, more than 160 expressed differentially proteins were detected in the PNF group, compared to 54 and 36 proteins in the EAD and OG groups respectively. However, they are 56:52:22 at the cold preservation stage. There are 22 and 17 commonly differentially expressed proteins at IRI phase and cold preservation stage respectively in 3 groups. Among them Liver-type fatty acid-binding protein (L-FABP) and F10A1 are differentially expressed during two liver injury time points. The tissue expression of L-FABP is negatively correlated and the serum levels of L-FABP is positively correlated with the degree of IRI.

Conclusions: The molecular basis of the susceptibility of different liver allografts to transplant injury is very complicated and we have made preliminary explorations and proved the biomarkers related to IRI.

Abstract# 633

Association of Immune Cell Markers with Adverse Outcomes in the First 6 Months Post-pediatric Heart Transplantation

J. Chen[1], D. Salerno[2], H. Corbo[1], S. Shah[3], A. Rothkopf[4], I. D. Lytrivi[4], *[1]Department of Pharmacy, Columbia University Irving Medical Center, New York, NY, [2]Department of Pharmacy, Weill Cornell Medical Center, New York, NY, [3]College of Pharmacy and Health Sciences, St. John's University, Queens, NY, [4]Pediatric Cardiology, Columbia University Irving Medical Center, New York, NY*

Purpose: Immunosuppression titration post-orthotopic heart transplant (OHT) is limited to trough level monitoring and does not provide data pertaining to overall state of immunosuppression. Additional tests of immune cell function assay (ICFA; ImmuKnow®) and CD3 count may be useful in discerning intensity of immunosuppression to avoid adverse outcomes.

Methods: Retrospective analysis identified OHT recipients 0-21 years of age transplanted at a large pediatric heart transplant center from 1/2018 to 12/2019. The co-primary outcome was difference in the median CD3 and ICFA within 30 days of either acute rejection or infection (defined as CMV/EBV DNAemia > 100 copies) within the first 6 months post-OHT. Patients received rabbit antithymocyte globulin (rATG) induction and maintenance immunosuppression with tacrolimus, mycophenolate mofetil, and rapid steroid withdrawal.

Results: A total of 57 patients were included comprising a combined 550 ICFA and CD3 values within the follow-up period. Age at transplant was 8.4 (IQR, 3-14.9) years, 59.7% were male, and median dosing of induction rATG used was 7.4 (IQR, 5.6-7.7) mg/kg total. There were 26 episodes of rejection and 17 episodes of infection, with the majority being in the first 2 months post-OHT. ICFA values preceding rejection were 282 (IQR, 152-419) ng/mL versus rejection-free periods of 174 (IQR, 71-356) ng/mL (p=0.014). CD3 counts preceding rejection were 169 (IQR, 32-418) cells/uL whereas rejection-free periods were 117.5 (IQR, 28-313) cells/uL (p=0.185). ICFA values were 184.5 (IQR, 46-280) ng/mL in those with infection and 191.5 (IQR, 88-366) ng/mL without infection (p=0.347). CD3 counts preceding infection were 186 (IQR, 73-321) cells/uL and 119 (28-327) cells/uL in those without infection (p=0.151) [Figure 1].

Conclusions: ICFA values preceding episodes of rejection were higher than in rejection-free periods. This association needs further investigation in clinical trials. CD3 values were neither associated with infection or rejection within the first 6 months post-OHT.

Abstract# 634

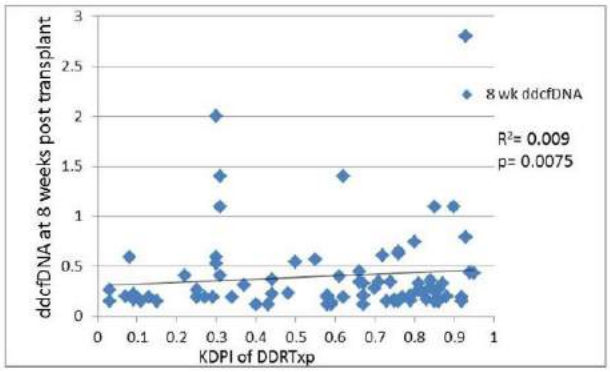
Impact of Deceased Donor Mode of Death and Kidney Donor Profile Index on Baseline Donor Derived Cell Free DNA in Kidney Transplant Recipients

B. Chopra, A. Grazier, K. K. Sureshkumar, *Allegheny Health Network, Pittsburgh, PA*

Purpose: Donor derived-cell free DNA (dd-cfDNA) is a novel serum biomarker available for earlier prediction of acute rejection in renal allograft. Baseline dd-cfDNA values are <1% in 96% of kidney transplant recipients (KTRs). We aimed to explore any differences in baseline dd-cfDNA levels among deceased donor KTRs stratified by the mode of donor death: donation after brain death (DBD) vs. donation after cardiac death (DCD). We also aimed to stratify baseline dd-cfDNA values according to different levels of kidney donor profile index (KDPI).

Methods: Our center has been checking dd-cfDNA levels (AlloSure, CareDx, Brisbane, CA) as for-cause and as surveillance in high immunological risk KTRs since 2018. We identified deceased donor KTRs at our center between April 2018 and June 2020 who had dd-cfDNA measured between 4 and 12 weeks post-transplant. A dd-cfDNA value ≥1.0% prompted allograft biopsy. Patient with biopsy evidence of rejection were excluded from the analysis since our aim was to compare baseline values. The average dd-cfDNA levels for each patient between 4 and 12 weeks post-transplant were compared between DBD and DCD KTRs and among the following KDPI groups: 0-20%, 21-50%, 51-84% and ≥85% using t test. A linear regression was constructed comparing dd-cfDNA levels with increasing KDPI.

Results: We identified 80 deceased donor KTRs with 189 dd-cfDNAA levels during the study period. There was no significant difference between average values of dd-cfDNA levels between DBD (n=59) and DCD (n=21) KTRs (0.45±0.39 vs.0.47±0.26, p=0.84). The average dd-cfDNA levels stratified by KDPI categories were as follows: 0-20% (n=11): 0.30±0.15; 21-50% (n=21): 0.49±0.30; 51-84% (n=34): 0.38±0.23 and ≥85% (n=14): 0.72±0.61. There was significant linear correlation between dd-cfDNA levels and increasing KDPI as shown in figure 1.



Conclusions: Mode of donor death did not impact baseline dd-cfDNA levels despite increased risk for ischemia-reperfusion injury and delayed graft function with DCD kidney transplantation. Significant linear correlation between baseline dd-cfDNA levels and increasing KDPI could be reflective of higher levels of ongoing intra-graft inflammation with increasing KDPI. Our study indicates that baseline dd-cfDNA could be influenced by different donor characteristics that define KDPI.

Abstract# 635

Gene Expression Profiles Assessed by the Nanostring nCounter® Platform May Differentiate Different Types of Rejection, and Importantly, T-Cell Mediated Rejection from BK Virus Nephropathy

K. R. Degner[1], K. J. Swanson[1], S. Parajuli[1], D. Mandelbrot[1], N. Garg[1], F. Aziz[1], M. Mohamed[1], W. Zhong[1], L. Ptak[1], N. A. Wilson[1], R. Woodward[2], A. Djamali[1], *[1]University of Wisconsin, Madison, WI, [2]CareDx, Inc., San Francisco, CA*

Purpose: Allograft biopsies are considered the gold standard for diagnosis and therapeutic guidance in kidney transplant recipients. Expanding current biopsy assessments to include gene expression signatures may further improve post-transplant monitoring and diagnosis; however, identification and validation of gene subsets for clinical use is required.

Methods: In this retrospective study, formalin-fixed paraffin embedded kidney allograft tissues from patients with confirmed antibody mediated rejection (ABMR, n=12), T-cell mediated rejection (TCMR, n=8) or BK virus nephropathy (BKVN, n=9) were analyzed using the Nanostring nCounter® platform (Nanostring Technologies, Inc., Seattle, WA). A panel of 758 immune related genes was assessed. Differentially expressed genes were rank-ordered using the Student's T-test and key genes identified as those with the greatest fold change (FC) and biological significance.

Results: Patients (n=28) were mostly white men (67%) with a mean age of 51 ± 14 years. Allograft biopsies were primarily for-cause biopsies (80%) performed due to de novo DSA or allograft dysfunction. Preliminary analysis revealed 60 genes differentially expressed between ABMR and BKVN (12 genes), TCMR and BKVN (32 genes) and ABMR and TCMR (16 genes). The strongest up- (FC≥2) or down (FC<0.5) regulated genes of the 60 genes that were identified are shown in Table 1. Upregulated genes helped characterize TCMR vs ABMR (15 genes, mean FC=6.8, range=5.2-13.9), and importantly TCMR vs BKVN (7 genes, mean FC= 2.6, range 2.4-3.7). Notably, *AIM2* and *BTLA* showed upregulation in TCMR compared to both ABMR (FC 5.2 and 6.1, respectively) and BKVN, although the change was more moderate in BK nephropathy (FC 2.5 and 3.4, respectively).

Table 1: Genes with Strongest Differential Expression

	TCMR vs ABMR	TCMR vs BKVN	BKVN vs. ABMR
Strongly upregulated (FC ≥ 2.0)	*AIM2, SELL, GBP5, LILRB4, ICOS, ANKRD22, FCGR1A, BTLA, C3, CALHM6, CD72, CTLA4, FPR1, LAG3, CCL18*	*PSTPIP1, CD48, NFAM1, CIITA, TNFSF8, CD86, STAT4*	None
Strongly downregulated (FC < 0.5)	*UMOD*	None	*HSD11B1, CXCL13*

Conclusions: Gene expression profiles assessed by Nanostring nCounter® platform may help differentiate ABMR from TCMR, and importantly, TCMR from BKVN. Additional studies are required to validate and confirm these findings

Abstract# 636

Combined Donor Derived Cell Free DNA (AlloSure) and Peripheral Immune Cell Gene Expression (AlloMap) Testing for the Diagnosis of Rejection in Kidney Transplant Recipients with De Novo Donor Specific Antibodies

K. R. Degner, S. Parajuli, F. Aziz, N. Garg, D. Mandelbrot, M. Mohamed, K. Van Hyfte, S. R. Reese, N. A. Wilson, A. Djamali, *University of Wisconsin, Madison, WI*

Purpose: Combined donor-derived cell-free DNA (dd-cfDNA, AlloSure) and peripheral immune cell gene expression (AlloMap) may increase the predictive value of de novo DSA (dnDSA) for the diagnosis of rejection in kidney transplant recipients.

Methods: Kidney transplant recipients undergoing an indication biopsy for dnDSA were eligible to participate. AlloSure and AlloMap testing was performed at the time of biopsy. Relationships between AlloSure, AlloMap, kidney function (serum creatinine, blood urea nitrogen, estimated glomerular filtration rate, urine protein creatinine ratio) and histopathology were assessed using Pearson correlation and logistic regression analyses.

Results: Participants (n=12) presented at a mean transplant to biopsy interval of 8.1±5.2 years with a mean DSA MFI of 15,356±16,076 (Class I-1,883±1,129 Class II-16,238±15,753). The majority of dnDSA were Class II DSA (75%), but Class I (8%) and combined Class I + Class II (17%) dnDSA were also observed. Rejection was diagnosed in 50% of patients. Of those, 67% were diagnosed with antibody mediated rejection (ABMR) and 33% with T-cell mediated rejection (TCMR). AlloSure results (threshold 1%) correlated with glomerulitis (r= 0.72, p=0.008), sum microvascular inflammation (r= 0.68, p=0.02), C4d (r= 0.72, p=0.01), vascular intimal thickening (r=0.58, p=0.05), basement membrane double contours (r=0.79, p=0.003), and mesangial matrix expansion (r=0.83, p=0.001) scores. There were no correlations between AlloSure and kidney function. AlloMap did not correlate with kidney function or histopathology. The negative predictive value (NPV) of AlloSure for rejection was 80% and the positive predictive value (PPV) was 71% [AUC = 0.75, 95% CI: 0.5-1.0, p=0.1]. The NPV of AlloMap (threshold set at population median score = 12.8) for rejection in patients with dnDSA was 67% and the PPV was 67% [AUC= 0.67, 95% CI: 0.3-1.0, p=0.3]. There were two patients with both AlloSure and AlloMap greater than the predefined thresholds who were diagnosed with rejection.

Table 1: Performance of AlloSure and AlloMap for Prediction of Rejection

	AlloSure (1%)	AlloMap (12.8)	AlloSure (1%) + AlloMap (12.8)
Sensitivity	67%	67%	33%
Specificity	83%	67%	100%
PPV	71%	67%	100%
NPV	80%	67%	60%

Conclusions: When combined with dnDSA, AlloSure correlated with disease activity and showed a relatively high NPV**.** The addition of AlloMap might improve the clinical value of dnDSA and AlloSure but additional studies are needed.

Abstract# 637

Renal Tubular-cell-specific Urinary Extracellular Vesicles: A Novel Biomarker for Diabetic Nephropathy After Kidney Transplantation

N. Eguchi[1], H. Lau[1], F. Zaldivar[2], U. G. Reddy[3], E. Tantisattamo[3], A. Ferrey[3], D. Dafoe[1], H. Ichii[1], *[1]Surgery, University of California Irvine, Orange, CA, [2]Pediatric Execise and Genomics Research Center, University of California Irvine, Irvine, CA, [3]Medicine, University of California Irvine, Orange, CA*

Purpose: Diabetes(DM) is a leading cause of ESRD among renal transplant recipients(RTRs). However, the kinetics of diabetic nephropathy recurrence after renal transplantation(RT) remains unclear. Currently, diabetic nephropathy, which involves damages to renal tubular cells, is diagnosed by allograft biopsy. Non-invasive methods that can detect renal tubular cell injury post RT may provide early diagnosis and guide prompt management to enhance graft survival. Urinary extracellular vesicles (UEVs) secreted by various types of renal cells contain cell-specific molecular cargos that may serve as an attractive source of diagnostic biomarkers for kidney diseases. This study aims to measure the level of renal tubular-cell-specific UEVs in RTRs with DM to determine whether renal tubular cell damage could be detected before clinical presentation.

Methods: UEVs from urine samples of healthy control RTRs (CTL, n=4), RTRs with DM without insulin dependency (NI-DM, n=4), RTRs with DM with insulin dependency (I-DM, n=4) were isolated within 24 hours. All patient's serum creatinine was in their baseline range. Insulin dependency was defined as the need for exogenous insulin therapy within 1 month of urine collection date. Isolated UEVs were stained with Annexin V, CD63, and Megalin antibody, and then analyzed by flow cytometry.

Results: The number of Annexin V- and CD63- positive UEVs was higher for I-DM ($1.4\pm0.43x10^5$UEVs) compared to CTL ($1.0\pm0.62 \times 10^4$UEVs, $p<0.5$) and NI-DM ($2.2\pm0.61 \times 10^4$UEVs, $p<0.5$). The number of renal-tubular-cell-specific UEVs were also significantly elevated in the I-DM group ($2.6 \pm1 \times 10^4$UEVs) compared to the CTL ($1.1\pm0.6 \times 10^3$UEVs, $p<0.5$) and NI-DM ($1.5\pm0.2 \times 10^3$UEVs, $p<0.5$) groups.

Conclusions: There is significantly higher numbers of renal-tubular-cell-specific UEVs present in I-DM group compared to CTL and NI-DM groups, suggesting that cell-specific UEVs may serve as a novel biomarker for renal tubular cell damage in RTRs with potential progression towards diabetic nephropathy.

Abstract# 638

Should We Worry About Covid-19 Infection in Pediatric SOT?

U. Ekong[1], S. Paul[1], S. Royal[2], J. Chahine[3], N. Yazigi[1], S. Kaufman[1], K. Khan[1], C. Matsumoto[1], A. Kroemer[1], T. Fishbein[1], *[1]Surgery, Medstar Georgetown Transplant Institute, Washington, DC, [2]Pediatrics, Medstar Georgetown University Hospital, Washington, DC, [3]Pathology and Laboratory Medicine, Medstar Georgetown University Hospital, Washington, DC*

Purpose: We describe the clinical presentation & immune response to COVID-19 infection in pediatric SOT.

Methods: Medical records of COVID-19 PCR+ or seropositive patients were reviewed for details of their disease course. Blood was obtained during PCR or seropositivity for immunophenotyping & PlexCOVID-19 test. PlexCOVID-19 measures frequencies of spike Ag reactive T cells that express CD154. A pre-established algorithm predicts likelihood of COVID-19 severity. Controls were peds SOT patients with negative COVID-19 status. RNA isolated from liver tissue for PCR using the Lyra SARS CoV-2 Assay. As induction of immunological memory is central to anti-pathogen adaptive immunity induced by infection, IHC of liver tissue for tissue resident memory cells (T_{RM}) (defined as $CD69^+$ expressing CD4 or CD8 T cells) was performed.

Results: 4 patients had COVID-19 & 5 patients were seropositive between March & Nov 2020 (Table 1). The 2 symptomatic PCR+ patients were hospitalized for 24-48-hours & the symptomatic seropositive patient had a prolonged PICU stay. Steroid was discontinued in 1 symptomatic PCR+ patient; & target CNI goal & steroid dose decreased in the symptomatic seropositive patient due to concurrent BK viremia. 8 patients remain well at home. Histology on 1 symptomatic PCR+ patient with elevated LFT's revealed lymphocytic portal inflammation & *SARS CoV-2* PCR on the liver was negative; histology on 1 asymptomatic seropositive patient was normal. Infrequent T_{RM} were seen on liver biopsies but were increased in PCR+ & seropositive biopsies vs. biopsies from same patients that pre-date a COVID-19+ status. $CD4^+$ T cells in PCR+ & seropositive patients had a phenotype consistent with activation, including expression of HLA-DR ($p = 0.008$); Further, BST2 was constitutively expressed on a subset of CD4+ T cells in PCR+ patients reflecting a history of IFN-alpha induced signals ($p=0.01$). The frequencies of spike Ag-reactive CD3 (0.95 ± 0.35 vs 2.73 ± 0.35, $p= 0.037$) and CD8 cells (1.10 ± 0.70 vs 5.03 ± 0.80, $p= 0.034$) were lower in symptomatic PCR+ patients compared with asymptomatic seropositive subjects.

Conclusions: A small number of our SOT patients had mild or asymptomatic CO-VID-19 infection, with notable activation of $CD4^+$ T cells, & constitutive expression of BST2 reflecting IFN-alpha induced signals. Spike-antigen-reactive T-cells was lower during symptomatic vs. asymptomatic infection.

Table 1. Patient demographics.

Subject ID	COVID-19 Status	Transplant Type	Duration from TX at diagnosis (years) Median (range)	Tacrolimus level (ng/ml) at diagnosis Median (range)	Absolute lymphocyte count at diagnosis Median (range)	Past corona (not COVID-19) virus infection
001	NP- PCR positive: asymptomatic	MVTx	2.1 (0.6 – 5.7)	7.5 (4.2 – 13.1)	3135 (1220 – 5039)	Type OC43
002	NP- PCR positive: asymptomatic	SLK Tx				None
003	NP- PCR positive: symptomatic	Isolated LT				Type HKU1

Abstract# 639

Urinary Exosome Mrna Signature for the Diagnosis of Human Kidney Transplant Rejection

R. El Fekih[1], J. Hurley[2], V. Tadigotla[2], A. Alghamdi[3], A. Srivastava[4], C. Coticchia[2], J. Choi[1], H. Allos[5], k. yatim[5], J. Alhaddad[5], S. Eskandari[5], P. Chu[5], A. Mihali[5], I. Lape[5], M. Lima Filho[5], B. Ayoma[5], A. Chandraker[5], K. Safa[6], J. Markmann[6], L. Riella[6], R. Formica[7], J. Skog[2], J. Azzi[5], *[1]Medecine, Brigham and Women Hospital, Boston, MA, [2]Exosome Diagnostics, Boston, MA, [3]Boston Children Hospital, Boston, MA, [4]Center for Translational Metabolism and Health, Chicago, IL, [5]Transplantation Research Center, Boston, MA, [6]Massachusetts General Hospital, Boston, MA, [7]Yale School of Medicine, New Haven, CT*

Purpose: Traditional biomarkers currently used to monitor the kidney allograft, such as creatinine and proteinuria, are late markers of injury and lack sensitivity, specificity and predictive abilities. The stability of urinary exosomes makes them a potentially powerful tool for liquid-biopsy and an ideal non-invasive diagnostic biomarker for kidney-transplant rejection

Methods: We collected 220 urine samples from 175 patients who underwent a clinically indicated kidney-transplant biopsy. Urinary exosomal mRNA were isolated using Exosome Diagnostics' EXOPRO Urine Clinical Sample Concentrator Kit and a differential gene-expression was used to develop rejection signatures. An initial panel of 586 TaqMan assays *(TaqMan® OpenArray® Human Inflammation)* for genes that have been studied as targets for a range of inflammatory diseases, and a subset 112 TaqMan assays were used to analyze the urine samples. The Boruta algorithm was used for feature selection. We used a repeated K-fold cross-validation (K=10, repeats=10) to generate the rejection probabilities. This allowed us to identify a 15-gene signature that distinguished biopsy with any cause rejection from no rejection. Furthermore, using the same approach, we have identified a 5-genes signature that distinguished TCMR from ABMR

Results: We have identified a 15-gene signature that discriminated biopsies with any-cause rejection from no-rejection. The area under the curve (AUC) was 0.90 (95% CI 0.85 - 0.96). Negative predictive value (NPV) for active rejection was 93.3% (95% CI 87.7% - 96.4%) and the sensitivity was 84.7% (95% CI 73.5% - 91.8%). The AUC for delta eGFR, was 0.57 (95% CI 0.49 - 0.65), which was significantly inferior ($p < 0.001$) to the performance of the multi-gene signature. A 5-gene signature that could distinguish TCMR from ABMR, was subsequently identified. The AUC for this signature was 0.87 (95% CI 0.76 - 0.97). If the second signature is negative, the patient has TCMR, and ABMR is ruled out with an NPV of 90.6% (95% CI 75.8% - 96.8%) and a sensitivity of 87.5% (95% CI 69.0% - 95.7%).

Conclusions: We show here that mRNA signatures derived from urinary exosomes represent a powerful and non-invasive tool to screen for kidney allograft rejection. This finding has the potential to assist clinicians in therapeutic decision-making

Abstract# 640

Intraoperative Fluid Management and Kidney Transplantation Outcomes: A Retrospective Review

M. W. Harbell[1], M. B. Kraus[1], S. A. Buckner Petty[2], J. W. Harbell[3], *[1]Anesthesiology and Perioperative Medicine, Mayo Clinic, Phoenix, AZ, [2]Biostatistics, Mayo Clinic, Phoenix, AZ, [3]Transplant Surgery, Mayo Clinic, Phoenix, AZ*

Purpose: Patients undergoing kidney transplantation have traditionally received liberal amounts of fluid during surgery to ensure adequate fluid volume and flow to the transplanted kidney. However, excessive fluids can lead to postoperative complications such as fluid overload, ileus, or pulmonary edema. Restrictive fluid strategies in other operations have been shown to be advantageous in shorter length of stays and faster return of bowel function. In this retrospective review, we compared the effect of restrictive versus liberal fluid therapy on kidney transplantation outcomes.

Methods: All patients who underwent deceased donor kidney transplantation at the Mayo Clinic Arizona between January 2014 and March 2019 were included in the study. Those who received less than 3 liters total intravenous fluids were considered "restrictive," whereas those who received 3 liters and greater were considered as receiving "liberal fluid therapy." The primary outcome was incidence of delayed graft function (DGF), which was defined as the need for dialysis within 7 days of transplant. Secondary outcomes included hospital length of stay, readmission within 30 days, return to the operating room, need for postoperative ventilation, need for intensive care unit level of care, time to return of bowel function, incidence of postoperative complications (myocardial infarction, arrhythmia, pulmonary edema, and pneumonia).

Results: 1171 patients were included in this study; 557 in the restrictive group and 614 in the liberal group. There were no differences in demographic or baseline characteristics between the two groups. The mean fluid intake in the restrictive group was 2.12 ± 0.55 L and was 3.56 ± 0.65 L in the liberal group. There was no difference in DGF (61.9% vs. 60.3%, p=0.557), length of stay (p = 0.342), readmission (p= 0.795), return of bowel function (p=0.707), or other postoperative complications in the restrictive and liberal fluid therapy groups.

Conclusions: Restrictive fluid therapy in deceased donor kidney transplantation was not associated with delayed graft function or worse outcomes compared to liberal fluid therapy. Restrictive fluid administration could be considered as part of enhanced recovery protocols for kidney transplantation without compromising kidney graft function.

Abstract# 641

Real-time Donor-derived Cell-free Dna Kinetics Indicate Decreased "Molecular Injury" During Treatment of Acute Renal Allograft Rejection

R. Hinojosa[1], K. M. Hitchman[2], D. J. Ross[3], R. C. Hall[1], J. E. Nelson[1], E. L. Kincaide[1], K. Klein[1], A. M. Bell[3], *[1]Pharmacotherapy Education and Research Center | Long School of Medicine, UT Health San Antonio | University Transplant Center, University Health, San Antonio, TX, [2]Long School of Medicine, UT Health San Antonio | University Transplant Center, University Health, San Antonio, TX, [3]CareDx, Inc., Brisbane, CA*

Purpose: Dd-cfDNA is a validated plasma analyte ($t_{½}$~30 min) for surveillance of renal transplant (KT) rejection with limited reports characterizing response to acute allograft rejection treatment.

Methods: Prospective, serial dd-cfDNA plasma levels (AlloSure®) were collected at renal allograft biopsy & prior to each treatment throughout the course of therapy for KTs with biopsy-proven acute rejection (BPAR). Kinetics during treatment for Δdd-cfDNA(%) & ΔSCr(mg/dL) were analyzed from time of biopsy (T_0) to treatment completion (T_1) by *Wilcoxon matched pairs signed rank* (p<0.05). *Simple linear regression* (p<0.05) was performed for Δdd-cfDNA *vs* ΔSCr. Individual treatment responses were determined 4 - 12 weeks later & deemed "successful" if ΔSCr<20%.

Results: Twelve KTs were analyzed median age 32 years (range 3-54). BPAR diagnoses included mixed [TCMR(1B-2B) + AbMR] (n=7), mixed [TCMR 1B+TMA] (n=1), AbMR (n=2), and TCMR 1B (n=2). Treatment included TPE (n=6), rATG(n=8), IVIG(n=6), rituximab(n=1), eculizumab(n=1), and steroids(n=12). A median of 6 (4 to 15) "treatment" dd-cfDNA levels were obtained per patient. Dd-cfDNA T_0-T_1 median of difference was 0.580% [p=0.007, median IQR 1.20% (0.245-3.575) το (T_1) 0.665% (0.175-1.075)]. SCr T_0-T_1 median of difference was 0.075 mg/dL [p=0.11, median IQR (T_0) 1.72 mg/dL (1.260-2.038) το (T_1) 1.56 (0.965-1.78)]. ΔSCr *vs* Δdd-cfDNA revealed no statistical correlation (R2=0.165; p=0.17). Of subjects with f/u: 7/9 (77.8%) had *"*successful*"* ΔSCr responses at a median of 4 weeks (2 - 12); and although no correlation was determined, 8/9 (88.9%) treatment-related Δdd-cfDNA achieved T_1 dd-cfDNA <1.0%, and 1/9 (11.1%) retained elevated SCr and dd-cfDNA. Four patients with stable SCr demonstrated worsening dd-cfDNA kinetics post-treatment of their initial rejection and revealed BPAR upon repeat biopsy. Early intervention in these patients did not allow progression to HLA-DSA formation or AbMR months after repeat treatment.

Conclusions: This novel analysis of dd-cfDNA kinetics links decreasing dd-cfDNA levels with resolving "molecular injury" during effective immunomodulatory treatment of BPAR, despite a lack of significant ΔSCr improvement. The T_1 dd-cfDNA levels had fallen to <1.0% for most subjects. Continued study is needed to investigate whether dd-cfDNA "treatment" kinetics can predict clinical outcomes of HLA-DSA escalation and/or chronic allograft loss. Dynamic kinetics of dd-cfDNA may present opportunity for patient-specific approaches to rejection treatment and earlier intervention that appears meaningful in preventing alloimmune response maturation to AbMR.

Abstract# 642

The Impact of Maintenance Immunosuppression Withdrawal on Sensitization Status After Renal Graft Failure

R. Hod Dvorai, A. Almonte, C. Hubbell, M. Laftavi, R. Shahbazov, R. Saidi, O. Pankewycz, J. Leggat, M. Hanlon, B. Gallay, *SUNY Upstate Medical University, Syracuse, NY*

Purpose: Maintaining immunosuppression (IS) following failed renal transplant may lead to increased risk for infections and malignancies; on the other hand, withdrawal can lead to sensitization and decreased chances for re-transplant. Our goal in this study was to assess the impact of immunosuppression withdrawal on sensitization status following renal graft failure.

Methods: We performed a retrospective analysis of patients who lost their renal graft between 1/1/2015 and 6/30/2020. Patients with no calculated Panel Reactive Antibody (cPRA) data prior and/or post graft loss (GL) and HLA-identical donor-recipients pairs were excluded from analysis. Demographic, HLA and biopsy data were extracted from patients' medical record. cPRA was calculated by assigning unacceptable antigens based on the Single Antigen Bead assay using a cut-off of 1000 MFI.

Results: Of the 29 patients who lost their graft during the study period, 9 (31%) were maintained on IS (IS group) and 20 (69%) were withdrawn (W/D group). Baseline

characteristics (Age at transplant, sex, donor source and HLA mismatch) were similar between the two groups. An increase in cPRA was noted in only 4 of the 9 patients in the IS group while cPRA rose in all 20 W/D group patients (p=0.001, Figure 1A and 1B). Interestingly, delta cPRA (calculated as the increase in cPRA from pre- to post-GL) was significantly higher in the W/D group than in the IS group (a median of 53.5% increase in cPRA vs 0%, p=0.003, Figure 1C). 8 of 11 patients in the W/D group with cPRA <10% prior to GL increased to cPRA >90% post-GL. 6 (30%) patients in the W/D group underwent nephrectomy (all 6 experienced an increase of >20% in cPRA following nephrectomy) versus no patients in the IS group, and 30% of the patients in the W/D group were re-transplanted versus 55.6% in the IS group, although, due to the small numbers this did not reach statistical significance (p=0.23).
Conclusions: Immunosuppression withdrawal after renal graft failure is associated with a significant increase in cPRA, potentially hindering the chance for a second transplant in these patients. Therefore, patients with a potential living donor or patients who are likely to be re-transplanted from a deceased donor may benefit from maintenance IS following graft loss.

Abstract# 643

Outcomes of Novel Coronavirus 2019 in Solid Organ Transplant Recipients: Yet Again, Race and Payor Status Matters

C. Huang[1], M. Hemmersbach-Miller[1], M. Goss[2], N. Moreno[3], A. Rana[1], J. Goss[1], N. Galvan[1], *[1]General Surgery, Baylor College of Medicine, Houston, TX, [2]General Surgery, University of Texas Health Science Center at Houston, Houston, TX, [3]General Surgery, McGovern Medical School, Houston, TX*

Purpose: By the early spring of 2020, the United States has become the global epicenter of the coronavirus 2019 (COVID-19) pandemic. Little is known if immunocompromised hosts such as solid organ transplant recipients are affected differently by COVID-19 - in terms of their presentation, their laboratory values, the management of their immunosuppression, and their outcomes. We describe a cohort of 25 solid organ transplant patients who were symptomatic and infected with COVID- 19 at a single institution at Baylor St. Luke's in Houston, Texas.
Methods: Using the electronic medical record, 25 solid organ transplant recipients (18 kidney, 2 liver/kidney, 2 liver, 2 heart, and 1 lung transplant) were identified with SARS-CoV2 infection from March 19th, 2020 until July 14th, 2020 at Baylor St Luke's Medical Center in Houston, Texas. We then cataloged their hospitalization course to include changes in immunosuppression therapy, need for intensive care, ventilator support, as well as COVID-19 directed therapy and report their outcomes.
Results: These patients have many comorbidities (96% with hypertension, 60% with heart failure or ischemic heart disease, and 60% with diabetes) alongside their immunocompromised status. Immunosuppression therapy was weaned in all but 2 stable liver transplant patients on minimal maintenance immunosuppression. Kidney SOTR patients often had atypical symptoms such as diarrhea (39%). Overall SOTR patients frequently presented with AKI (44%), frequently required ICU stay (52%), and frequently required intubation (36%). Notably, we discovered a large racial/ethnic disparity in COVID-19 infection as all our patients are minorities and 24 of 25 patients are of Hispanic ethnicity or African American race. In addition, 72% of our infected patients had Medicare or Medicaid as their primary health insurance - compared to our baseline of 46%.
Conclusions: We have found solid organ transplant patients had more atypical symptoms such as diarrhea and CT imaging can be more accurate and timely in diagnosis. In regards to clinical management, a stepwise reduction/discontinuation of immunosuppression based on disease severity appears to be a safe and pragmatic model of care. Furthermore, we too have found that a significant racial and ethnic disparity exists for African-American and Hispanic transplant recipients becoming infected with COVID-19. Yet again, minorities and those more socioeconomically disadvantaged continue to bear the brunt of chronic disease, even after they receive their transplantation.

Abstract# 644

A Reliable Non Invasive Alternative to Surveillance Renal Allograft Biopsy

R. Jain, S. Thaduri, V. Kumar, C. Kew, B. Julian, G. Towns, S. Ong, F. Ahmed, S. Mehta, G. Agarwal, *Transplant Nephrology, University of Alabama Birmingham, Birmingham, AL*

Purpose: Surveillance Renal Allograft Biopsy (SAVB) is the standard of care to identify subclinical immunological injury(SCI). However fewer than 25% of transplant centers in the US perform SVAB, as it has a low rate of positive results, involves procedure risks, and has logistical issues. Donor derived cell free DNA (dd-cfDNA) is gaining acceptance as a non-invasive biomarker of immunological injury in renal allografts with a negative predictive value (NPV) exceeding 84%. We propose using a combination of dd-cfDNA and DSA to enhance the NPV as an alternative to SVAB .
Methods: Retrospective, single center chart review of 174 consecutive patients undergoing SVAB between 02/02/2019 to 09/20/2020 with paired results of dd-cfDNA and DSA.Data regarding patient demographics, induction agents, etiology of ESRD and CPRA status was collected.

Criteria for Positive Test Results	
dd-cf DNA	>1%
DSA	>1500 Mfi
Biopsy	Cellular Rejection(Banff Borderline or higher) and/or Antibody Mediated Rejection

Results: Patient characteristics were comparable to most Renal Transplant centres in the US.Using dd-cf DNA for diagnoses has a higher specificity of 93% at the expense of missing 2.29% patients who could have SCI on SVAB.

Comparing SVAB to dd- cf DNA alone		
	SVAB Positive	SVAB Negative
dd-cf DNA Positive	4 TP	11 FP
dd-cf DNA Negative	7 FN(2%)	152 TN(87%)

Combination of dd-cf DNA with DSA has NPV of 98% and could safely avoid SVAB in up to 77% of the population with a chance of missing SCI in only 1.72% of patients

Comparing SVAB to dd-cf DNA and DSA		
	SVAB Positive	SVAB Negative
dd-cf DNA or DSA Positive	8 TP	29 FP
dd-cf DNA and DSA Negative	3 FN(1.72%)	134 TN(77%)

Identification of SCI					
	Sensitivity	Specificity	PPV	NPV	Accuracy
dd-cf DNA	36%	93%	27%	96%	90%
dd-cf DNA + DSA	73%	82%	22%	98%	82%

Conclusions: Use of dd-cfDNA is a useful screen for SCI after transplant with a high NPV. Adding DSA to dd-cfDNA further improves the NPV to 98%. Thus, a combination of negative dd-cfDNA & DSA can be used as a safe non invasive alternative to SVAB.

Abstract# 645

Characteristics, Risk Factors, and Outcomes of Neutropenia for the First Year After Liver or Kidney Transplantation in Children

C. Jarasvaraparn[1], S. Choudhury[2], C. Rusch[2], K. Liss[1], J. Stoll[1], S. Hmiel[3], S. Kulkarni[1], *[1]Pediatric Gastroenterology, Washington University School in St Louis, Saint Louis, MO, [2]Pediatric, Washington University School in St Louis, Saint Louis, MO, [3]Pediatric Nephrology, Washington University School in St Louis, Saint Louis, MO*

Purpose: Prior studies in adults have shown that approximately 20-38 % of subjects undergoing solid organ transplant develop neutropenia. In the current study, we characterized the incidence, risk factors and morbidity of neutropenia in pediatric (≤ 18 years at transplant) recipient of liver (LT) and kidney (KT) allografts.

Methods: We conducted a retrospective chart review of LT and KT recipients at our center during the period 2008-18. All of the KT and none of the LT subjects during this time period had induction with either ATG or basiliximab at time of transplant. Neutropenia was defined as absolute neutrophil count (ANC) value ≤ 1,000/mm^3.

Results: Ninety-eight subjects with LT and 82 subjects with KT were included. Despite the mean ANC being significantly lower in neutropenic LT (3±2.5) subjects compared to neutropenic KT subjects (4.2±2.5) at the time of transplant (p=0.04), the incidence of neutropenia within the first year of transplant in KT (57.3%) was higher compared to LT (38.8%) (p=0.01).The mean number of hospitalizations (p=0.001) and infectious complications (p=0.03) were significantly higher only in the KT subjects who developed neutropenia (compared to those who did not), but not in LT subjects. Binary logistic regression analysis revealed that prior upper gastrointestinal bleed (p=0.03), weight deficit before transplant (p=0.01), CMV infection (p=0.04) and ANC before transplantation (p=0.02) predicted neutropenia in LT subjects, while female gender (p=0.04) and BK virus infection (p=0.04) predicted neutropenia in KT subjects. Surprisingly, the doses of valgancyclovir, mycophenolate and TMP/SMX were not associated with neutropenia in either LT or KT subjects.

Conclusions: The incidence of, and morbidity associated with neutropenia within 1 year post transplant is higher in KT subjects compared to LT subjects. Factors which indicate more severe liver disease at transplantation and CMV infection after transplantation were associated with neutropenia. Similar to our finding, BK virus infection has been shown by a prior study to be associated with neutropenia.

Table Patient demographics and baseline characteristics

Characteristics	Liver Transplantation			Kidney Transplantation			Neutropenia group in LT and KT
	Non-Neutropenia N = 60	Neutropenia N = 38	P value	Non-Neutropenia N = 35	Neutropenia N = 47	P value	P value

Abstract# 646

Leukopenia in the Renal Transplant Population

A. Johnson[1], G. Karadkhele[2], C. Larsen[1], *[1]Emory University, Atlanta, GA, [2]Surgery, Emory University, Atlanta, GA*

Purpose: Leukopenia is a common complication for transplant patients on immunosuppression, but etiologies, timing, and outcomes are only superficially understood.

Methods: All patients undergoing kidney transplant at Emory University Hospital between the years 2009 and 2019 were included. Using CTCAE definitions, moderate leukopenia was defined as lowest white blood cell (wbc) value between 1 and 2, and severe leukopenia was defined as lowest wbc <1. We explored longitudinal measures of leukopenia to determine the relevance of patterns of wbc levels. Longitudinal leukopenia was measured by the integral of 2-wbc over the first year post transplant, representing the amount of time the patient spent with a white blood cell count of less than 2. This AUC (area under the curve) was adjusted for length of follow-up, multiplying by a factor of 365/days of follow-up. Survival and graft loss at 3 years post transplant was analyzed in the context of these two different measures.

Results: Of 2059 patients, 61% were on belatacept and 39% on tacrolimus immunosuppression. 104 patients had severe and 367 had significant leukopenia. Age, sex, race, and etiology of renal disease were equally balanced between groups. Patients with significant or severe leukopenia were more likely to have received a kidney from a deceased donor, to be CMV high risk, and to be on immunosuppression with tacrolimus or azathioprine. On multivariate regression controlling for donor type, azathioprine use, and cmv risk status, immunosuppression with tacrolimus was no longer associated with leukopenia. 62% of patients with severe leukopenia experienced CMV viremia, while 48% had undergone treatment with thymoglobulin. Thirty patients had severe leukopenia not explained by CMV viremia or prior thymoglobulin treatment. When quantified using CTCAE definitions, 24% of patients with severe leukopenia versus 19% of patients with significant leukopenia, and 8% of patients without leukopenia experienced graft loss or death at 3 years. Surprisingly, for significant and severe patients, AUC was not significantly associated with graft loss or death.

Conclusions: While there are significant differences in protective immunity for patients on belatacept and tacrolimus, the incidence of leukopenia in these populations does not appear to be different. In our patients, leukopenia in the first year transplant was associated with increased rates of graft loss and death, underscoring the need to develop management pathways for these at-risk patients. Further study is warranted to understand this population.

Abstract# 648

Incidence of Pancreatic Exocrine Insufficiency in Patients Undergoing Liver Transplantation

J. Klein[1], M. Rangel[1], I. Ifearulundu[1], Y. Gely[1], Z. Spigel[2], S. Janardhan[3], M. Hertl[1], E. Chan[1], *[1]Surgery, Rush University Medical Center, Chicago, IL, [2]Surgery, Allegheny Health Network, Pittsburgh, PA, [3]Hepatology, Rush University Medical Center, Chicago, IL*

Purpose: The purpose of this study was to determine the incidence of Pancreatic Exocrine Insufficiency (PEI) in patients undergoing liver transplantation. Furthermore, patient-specific risk factors were identified, allowing for early recognition of PEI and treatment in order to improve malnutrition and post-transplant outcomes.

Methods: A retrospective chart review of 296 consecutive patients undergoing liver transplantation at a single institution over 5 years was performed. After inclusion and exclusion criteria were applied, 33 patients were used for data analysis (Figure 1). Data collected included age, etiology, presence of diabetes, nutritional status prior to transplantation, and result of fecal elastase test. Survival data were compared to a control group (n=263) not receiving pancreatic enzymes.

Results: 33 charts were reviewed after having met inclusion criteria. The etiology of cirrhosis for transplant included NASH (5/33, 15.2%), alcoholic cirrhosis (17/33, 51.5%), hepatitis C (7/33, 21.2%) and cryptogenic (4/33, 12.1%). 18 patients (54.5%) were noted to have PEI, defined as fecal elastase <200 ug/g. There was a difference in rate of PEI (p=0.0059) when comparing different etiologies of cirrhosis. Rate of PEI in included patients with Hepatitis C (7/7, 100%) was highest, followed by cryptogenic (3/4, 75%), NASH (3/5, 60%) and alcohol (5/17, 29.4%). There was a significant difference in 1-year mortality among patients tested for PEI and those who weren't (p=0.009). For comparison by etiology see Figure 2.

Conclusions: Symptomatic patients who were screened for PEI had a positivity rate of 54.5% (18/33). The cause of their cirrhosis played a significant role in the develop-

ment of PEI, with Hepatitis C as the etiology most frequently associated with PEI and alcohol the least. Survival in general was significantly better for patients tested for PEI, suggesting a survival benefit of patient screening before transplantation. Further investigation into additional risk factors, as well as differences in outcomes with early supplementation, seems warranted.

Abstract# 649

De Novo Donor Specific Antibodies After Heart Transplantation in Fontan Patients with Protein Losing Enteropathy

D. A. Magnetta[1], V. Hoch[2], D. Pinelli[3], M. Monge[4], E. Pahl[1], P. T. Thrush[1], *[1]Pediatric Cardiology, Lurie Children's Hospital, Chicago, IL, [2]Northwestern School of Medicine, Chicago, IL, [3]Department of Surgery, Northwestern University Feinberg School of Medicine, Chicago, IL, [4]Pediatric Cardiothoracic Surgery, Lurie Children's Hospital, Chicago, IL*

Purpose: Protein Losing Enteropathy (PLE) complicates Fontan physiology and can be an indication for heart transplantation (HT). PLE is accompanied by immune dysregulation, potentially impacting antibody production; the impact of PLE on the development of donor specific antibodies (DSAs) is unclear. De novo DSAs (dnDSAs) incur graft damage, increasing risk for rejection and coronary artery vasculopathy. We investigated the development of dnDSAs in the first year after HT in Fontan patients with and without PLE.

Methods: A retrospective chart review was conducted of Fontan patients who underwent HT at our institution. Diagnosis of PLE was based on clinical features and/or laboratory data. Patients were excluded if they lacked pre-transplant or post-transplant DSA data. Characteristics between the two groups were compared using Wilcoxon Rank Sum and Fisher's Exact Test as appropriate. Freedom from dnDSAs and 1 year graft survival were assessed using Kaplan Meier curves and compared using the Log Rank Test.

Results: Over the 12 years, 51 Fontan patients underwent HT and had sufficient antibody data. Twenty-eight (55%) had PLE and 23 (45%) did not. Baseline demographics were similar between those with and without PLE. Peak panel of reactive antibodies (PRA) prior to HT was similar for both Class 1 (no PLE: 4[0-41%] vs PLE: 6[0-48%], p=0.61) and Class 2 (no PLE: 0[0-19%] vs PLE: 0[0-25%], p=0.55) antibodies. Freedom from class 1 dnDSA post-HT was the same between two groups (Figure 1A). Though not statistically different, there was a trend towards lower freedom from class 2 dnDSA in the PLE group (Figure 1B). Graft survival was similar between the two groups.

Conclusions: Despite similar pre-HT PRA, Fontan patients with PLE trended towards earlier class 2 dnDSAs, however this study may have been underpowered to detect true differences. Early graft survival did not differ between the groups. A larger scale analysis would offer insight into the risk of dnDSA production and long term graft failure in Fontan patients transplanted for PLE.

Abstract# 650

Brain Natriuretic Peptide and Pedometer Activity are Most Predictive of Poor Kidney Transplant Waitlist Outcomes

P. Manay[1], P. TenEyck[2], R. Kalil[3], M. Sanders[4], M. Swee[4], G. Binns[5], J. Hornikel[5], D. Katz[1], *[1]Department of Surgery, University of Iowa, Iowa City, IA, [2]Institute for Clinical and Translational Science, University of Iowa, Iowa City, IA, [3]Department of Medicine, University of Maryland Medical Center, Baltimore, MD, [4]Department of Medicine, University of Iowa, Iowa City, IA, [5]Iowa City VAMC, Iowa City, IA*

Purpose: Tools for indicating which patients are most at risk for complications and death after transplant listing would allow for a rational approach to targeted waitlist management.

Methods: Following IRB approval, demographics, frailty metrics, pedometer, treadmill ability (METS), troponin, and BNP were collected on 314 patients listed for kidney transplant between July 2015 and March 2020 and three subsequent listing update visits. Frailty metrics included handgrip, chair sit/stand, 8 foot up-and-go, sit/reach, and exhaustion questions. Calibrated pedometer activity was recorded over several days and measured as steps/time. After patients with missing data were eliminated, univariate and multivariate logistic regression models were fit to assess the association of measures with delisting for death or medical complications in 283 remaining patients. Model fits of the predictor subsets for each outcome were compared using the Akaike information criterion (AIC). Additional logistic modeling was conducted on 84 patients with multiple visits and included change in metrics over time to test if progression and time between visits was predictive of waitlist outcomes. AIC was used to identify optimal covariate sets considered in our modeling. We assessed the significance of individual predictors at the alpha = 0.05 level.

Results: Mean age was 59.9 years, 95% male, 57% White, 30% Black, 9.5% Hispanic. Mean BMI was 29.6. Diabetes was the primary cause of ESRD (45%), followed by HTN (15%), FSGS (9%), and ADPKD (7.6%). Reasons for delisting were medical (DLM, n=43), death on list (DOL, n=20) and other (n=9). The mean (SD) time between first and last follow-up was 2.09 (0.84) years. BNP was the most consistent univariate predictor of DLM and DOL (both $p<0.0001$). Factors at initial listing significantly associated with DOL on multivariate analysis included higher BNP ($p<0.0001$) and lower steps/time ($p=0.015$). Lower METS and steps/time, and high BNP were associated with delisting for medical reasons on multivariate analysis ($p<0.05$). Considering change in metrics over time, declining steps/time was associated with DLM ($p<0.0001$) and DOL ($p=0.0127$). Worse performance on treadmill (METS) and chair sit/stand were associated with DLM ($p=0.0086$) and DOL ($p=0.048$), respectively. Increase in BNP values consistently predicted DLM ($p<0.0001$) and death at any time after listing ($p<0.0001$).

Conclusions: BNP and pedometer activity at time of listing and changes in BNP over time were significantly associated with kidney transplant waitlist outcomes. Functional metrics and BNP screening can identify patients in need of more intense waitlist management.

Abstract# 651

The Assesment of Pre-transplant Donor-reactive IL-21 Producing T Cells as a Tool to Identify Patients at Risk for Acute Rejection

A. Mendoza Rojas[1], T. van Gelder[2], R. de Kuiper[1], D. Reijerkerk[1], M. C. Clahsen-van Groningen[3], D. A. Hesselink[1], C. C. Baan[1], N. M. van Besouw[1], *[1]Internal Medicine, Neprology & Transplantation, Erasmus Medical Center, Rotterdam, Netherlands, [2]Department of Clinical Pharmacy & Toxicology, Leiden University Medical Center, Leiden, Netherlands, [3]Internal Medicine, Pathology, Erasmus Medical Center, Rotterdam, Netherlands*

Purpose: The measurement of panel-reactive antibodies (PRA) has proven valuable in the transplant setting but it does not account for the presence of donor-reactive memory T cells. Previous studies have shown that these cells are associated with the development of acute rejection. The aim of this study, was to assess whether pre-transplant memory T and B cell alloreactivity are associated with increased rejection risk of kidney transplant recipients.

Methods: Peripheral blood mononuclear cell (PBMC) samples from 114 kidney transplant recipients (transplanted between 2010-2013) were obtained pre-transplantation. The number of donor-reactive IL-21 (cytokine known to provide help to B cells) producing T cells was analyzed by enzyme-linked immunospot assay (Elispot). Patient cells were stimulated with irradiated donor cells. Historical PRA and/or the presence of serum anti-HLA antibodies were used to determine the presence of B cell alloreactivity before transplantation.

Results: A total of 30 patients developed acute rejection within 6 months after transplantation. Pre-transplant B cell alloreactivity was present in 16/30 (53%) patients with rejection and 33/84 (39%) patients with no rejection. The number of donor-reactive IL-21 producing T cells was significantly higher in patients with rejection (p=0.03). A ROC curve to assess the reliability of donor-reactive IL-21 producing T cells in predicting rejection, resulted in an AUC of 0.638 with a sensitivity of 0.63 and specificity of 0.60 (PPV: 21.5% and NPV: 90.1%). Multivariate binary logistic regression showed that donor age (OR: 1.057, 95% CI 1.017- 1.098) and number of donor-reactive IL-21 producing T cells (OR 1.015, 95% CI 1.003- 1.026) were indicators of an increased risk for the development of rejection (p=0.008).

Conclusions: The number of pre-transplant donor-reactive IL-21 producing T-cells is an independent predictor for the development of acute rejection within the first 6 months after kidney transplantation. In contrast, pre-transplant B cell alloreactivity was not significantly related to incidence of rejection. Our data form a good starting point for research into the added value of monitoring pre-transplant donor-reactive IL-21 producing T-cells for assessment of immunological risk.

Abstract# 652

Immunosuppression is Not Associated with High-risk Immunologic Parameters in Transplant Recipients with the Sars-cov2 Virus

S. Merl, R. Jones, B. Shonts, D. Rust, M. Sykes, J. Weiner, *Medicine/Surgery, Columbia University Medical Center, New York, NY*

Purpose: The factors associated with severe COVID-19 disease in transplant patients are poorly understood. Despite concern that patients with weakened immune responses have increased risk of infectious complications, we hypothesized that immunosuppression might attenuate the inflammatory cascade that characterizes severe disease. We therefore evaluated whether disease severity is associated with various immune parameters.

Methods: We characterized lymphocyte phenotypes using flow cytometry and measured cytokines by Luminex in 5 transplant recipients with the SARS-CoV2 virus. The ImmuKnow assay, which measures ATP in stimulated CD4 cells, was utilized to assess cell-mediated immunocompetence.

Results: Higher ImmuKnow levels correlated with more severe clinical course. We found a significant linear correlation between ImmuKnow level and percentage of activated effector (CCR7-/CD69+) CD4 (p=0.042) and CD8 (p=0.003) cells in the blood as well as the CD4:CD8 ratio (p=0.001) (Table 1). In two lung secretion samples, higher ImmuKnow level correlated with a higher percentage of resident memory (CCR7-/CD69+/CD103+) CD8 T cells. Concentrations of G-CSF, IL-10, IL-6, TNF-a and MCP1 were elevated in at least 50% of our cohort and highest in the patient with the highest ImmuKnow level.

Conclusions: Higher ImmuKnow levels correlated with more severe clinical course, higher percentages of activated effector CD4 and CD8 cells and CD4:CD8 ratio in the blood, higher percent of resident memory CD8 cells in the lung secretions, and higher levels of inflammatory cytokines. These are all factors described in patients with more severe disease, suggesting that increased immunosuppression does not increase the risk of severe COVID-19 outcomes in transplant patients.

Table 1

	Clinical Course	ImmuKnow	% CCR7-/69+ of Blood CD4+	% CCR7-/69+ of Blood CD8+	Blood CD4:CD8 Ratio	% CCR7-/69+/103+ of Lung Secretion CD8+
Patient 1	Severe disease, discharged to facility with trach	341	15.2	63.6	0.7	36.6

Abstract# 653

Endothelial Glycocalyx Shedding is Associated with Graft Quality During Ex Vivo Lung Perfusion

K. Noda, B. J. Philips, T. Harano, J. D. Luketich, P. G. Sanchez, *Department of Cardiothoracic Surgery, University of Pittsburgh, Pittsburgh, PA*

Purpose: Endothelial glycocalyx is the surface protective layer of the endothelial cells and its damage is known to be strongly associated with organ dysfunction. However, the impact of endothelial glycocalyx integrity and donor lung quality are unknown. In this study, we investigated the association between glycocalyx integrity and graft quality using an *ex vivo* lung perfusion (EVLP) platform.

Methods: We analyzed perfusate obtained from clinical EVLP using marginal lungs from brain death (BD) donor and donor after circulatory determination of death (DCD). Heparan sulfate and syndecan-1 levels were defined as markers of endothelial glycocalyx degradation. Graft transplantability was comprehensively defined based on graft function, physiology, radiographic, bronchoscopic and surgical assessments. Data were compared between graft quality (transplanted or declined) and/or donor type.

Results: Of 39 total EVLP cases analyzed (24 BD and 15 DCD), seventeen BD lungs and nine DCD lungs were transplanted after EVLP. Declined for transplant lungs showed radiographic, bronchoscopic and surgical assessments signs of edema/bogginess. In addition, declined lungs displayed increased EVLP perfusate levels of syndecan-1 (Figure 1A). Overall, no significant physiologic EVLP parameter differences were observed between transplanted and declined lungs. While no association was found between EVLP perfusate heparan sulfate concentrations and graft transplantability in BD lungs, perfusate heparan sulfate levels were significantly higher in declined DCD lungs compared to transplanted DCD lungs (Figure 1B).

Conclusions: Our data demonstrate that endothelial glycocalyx shedding during EVLP is associated with the decision to transplant or not transplant. In particular, increased fragility of the glycocalyx was observed in DCD lungs. These findings suggest that strategies for preserving and repairing the vascular endothelial glycocalyx may improve graft quality. Further investigation is required to demonstrate a clear association between glycocalyx shedding and posttransplant outcomes.

Abstract# 654

Hla-dq Epitope Mismatch Predicts De Novo Donor-Specific Antibody Formation and Acute Cellular Rejection After Living Donor Liver Transplantation

K. Ono, K. Ide, Y. Tanaka, M. Ohira, H. Tahara, N. Tanimine, S. Akimoto, Y. Imaoka, K. Sato, H. Yamane, N. Tsukiyama, R. Ide, T. Mochizuki, H. Ohdan, *Department of Gastroenterological and Transplant Surgery, Graduate School of Biomedical and Health S, Hiroshima University, Hiroshima City, Japan*

Purpose: Epitope mismatch (MM) effect on living donor liver transplantation (LDLT) has not been studied in detail. This study aimed to investigate the role of epitope MM in predicting de novo donor-specific antibody (dn-DSA) formation and the relationship between epitope MM and T cell immune response in LDLT.

Methods: Forty-five recipients (39 ABO-blood-type compatible, 6 ABO incompatible) were enrolled. Epitope MM levels for HLA class I (A, B, C) and class II (DRB1, DQB1) were determined by HLAMatchmaker. For all recipients, anti-HLA antibodies were analyzed before and annually after transplantation. Mean fluorescence intensity (MFI) above 1,000 for DSAs against HLA-A, -B, -C, -DRB1, and -DQB1 was considered positive. Recipient T-cell responses to allostimulation were evaluated by MLR assay before LDLT. $CD4^+$ and $CD8^+$ T-cell stimulation index (SI) and CD25 expression in proliferating $CD8^+$ T-cells were quantified using multiparameter FCM analysis.

Results: Nine patients (20%) developed dn-DSAs; almost all dn-DSAs were against HLA class II antigens. Total HLA allele MM and HLA-A, -B, -C, -DRB1 and -DQB1 allele MM were not associated with dn-DSAs. Patients with dn-DSAs had a significantly higher number of HLA-DQ epitope MMs (7.8 ± 3.0 vs. 4.6 ± 5.4, $P<0.05$). The probability of dn-HLA-DQB1 DSA formation was higher for the patients with >9 HLA-DQ epitope MMs. A receiver operating characteristic (ROC) analysis showed that the number of HLA-DQB1 epitope MMs was strongly predictive of dn-HLA-DQ DSA (area under the curve [AUC], 0.771; $P<0.01$). Patients with ACR in the first month had a higher number of HLA-DQ epitope MMs (8.7 ± 6.7 vs. 4.6 ± 4.6; $P<0.05$). The probability of ACR was higher for HLA-DQB1 epitope MMs >7. ROC analysis for ACR showed strong predictive values of HLA-DQB1 epitope MMs (AUC, 0.728; $P<0.05$). There was no significant difference in the SI for the $CD4^+$ and $CD8^+$ T-cell responses in patients with low-(<7) and high-load (≥7) of HLA-DQB1 epitope MM. However, the CD25 expression in proliferating $CD8^+$ T-cells was higher in the high-load patients.

Conclusions: HLA-DQB1 epitope MM is associated with dn-DSA formation and ACR after LDLT. Further studies are required to evaluate the clinical utility of epitope matching.

Abstract# 655

Dietary Intake and Mycophenolate Mofetil-related Diarrhea Following Kidney Transplantation

G. Onyeaghala[1], L. Teigen[2], B. Guo[2], Y. Doronin[1], M. Al-Kofahi[2], B. Wu[2], W. Guan[2], C. Staley[2], S. Riad[2], A. Matas[2], R. Remmel[2], W. Oetting[2], C. Dorr[1], P. Jacobson[2], A. Israni[1], *[1]Nephrology, Hennepin Healthcare Research Institute, Minneapolis, MN, [2]University of Minnesota, Minneapolis, MN*

Purpose: The treatment of Mycophenolate mofetil (MMF) related diarrhea in kidney transplants recipients involves providing lower MMF doses more frequently to maintain the same daily dose. However, this fractionated dosing regimen is associated with reduced adherence to immunosuppression and poor outcomes. We hypothesized that dietary fiber or polyols intake post-transplantation would be associated with MMF-related diarrhea.

Methods: The Microbiome and Immunosuppression in Kidney Transplantation (MISSION) study used Mosio, Inc (Seattle, WA) to implement a HIPPA compliant text-based survey. The survey was sent for up to 6 months post-transplant on a bi-weekly basis, to collect diarrhea information from 8 participants receiving MMF and Tacrolimus. Diarrhea events were defined using the V 5.0 definition of the National Cancer Institute's Common Terminology Criteria for Adverse Events (CTCAE). The cohort was dichotomized based on development of diarrhea events of CTCAE grade 2 (increase of 4-6 stools per day compared to the previous week). Baseline 48-hour food recalls were collected one-week post-transplant for 7 of the 8 participants using the Nutrition Data System for Research.

Results: Over 4 months of follow up, 242 diarrhea surveys were completed and 15 diarrhea events were reported (**Figure 1**). The median time to the first reported diarrhea event was 17.5 days post-transplant (range: 2-79 days). We did not observe a difference in dietary fiber intake based on diarrhea outcomes. However, participants who developed diarrhea appeared to have higher intake of the polyols mannitol (median: 0.45g, range: 0.43-0.47g) and sorbitol (median: 0.03g, range: 0.02-0.1g), compared to participants who did not (median: 0.04g, range:0.02-0.24g and median 0g, range: 0-0.01g for mannitol and sorbitol, respectively) (**Table 1**).

Conclusions: These preliminary findings suggest an increased dietary intake of polyols may contribute to the development of MMF related diarrhea. Mannitol and sorbitol have an osmotic action in the small intestine and are readily fermented by colonic bacteria, leading to altered bowel habits. The prospective collection of diarrhea, nutrition and microbiome data will contribute to future interventions to reduce incidence of MMF-related diarrhea in kidney transplantation.

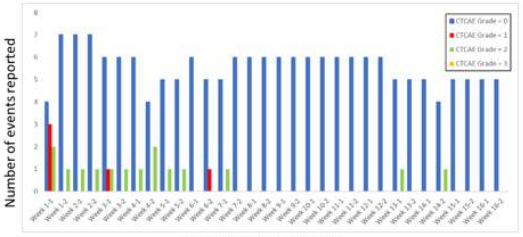

Figure 1. Frequency of MMF-related diarrhea during the first 4 months of follow up

Table 1: Dietary intake between patients with and without diarrhea

	No diarrhea (n=4) Median (Min, Max)	Developed diarrhea (n=3) Median (Min, Max)
Fiber	13.5 (3.8, 55.6)	20.8 (18.1, 22)
Soluble Fiber	5.2 (0.9, 14.4)	6.5 (5.2, 7.0)
Mannitol	0.04 (0.02, 0.24)	0.45 (0.43, 0.47)
Sorbitol	0 (0, 0.01)	0.03 (0.02, 0.1)

Abstract# 656

Comparison of Donor-derived Cell Free Dna Between Recipients with First Solitary Allograft and Regrafts

S. Paluri[1], S. Muthusamy[1], M. Shinbashi[1], G. Gupta[1], B. Dale[2], Z. Kashi[3], P. Halloran[4], D. Kumar[1], *[1]Virginia Commonwealth University, Richmond, VA, [2]CareDx, Brisbane, CA, [3]Kashi Clinical Laboratories, Portland, OR, [4]ATAGC, Edmonton, AB, Canada*

Purpose: Donor derived-cell free DNA (dd-cfDNA) is a biomarker of immunological injury. Multiple studies have validated its utility in recipients of first solitary kidney transplants (s-KT) while its utility in regrafts with previous in-situ failed kidney transplants (r-KT) who conceivable have a second source of dd-cfDNA is not yet fully defined. Here we present our findings and comparison of values in patients with no rejection, any rejection or ABMR by both histology and molecular microscope.

Methods: In our center all KT biopsies in addition to histological assessment also undergo dd-cfDNA (Allosure, CareDx) and molecular microscope (MMDx; ATAGC; Canada) analysis. We evaluated eighty-seven KT biopsies with no rejection, by histology and MMDx. Seventy-eight KT biopsies with evidence of any rejection by histology and MMDx. Finally, we evaluated fifty-three KT biopsies with evidence of only ABMR by both histology and MMDx.

Results: KT biopsies with no rejection, seventy (70/87; 80%) biopsies were performed on s-KT and seventeen (17/87; 20%) were on r-KT. The main indication for biopsy in each group was surveillance (s-KT 30/70; 42% vs r-KT 12/17; 70%) followed by AKI (s-KT 22/70; 31% vs r-KT 4/17; 24%) The median dd-cfDNA in the r-KT group was 0.30% (IQR: 0.21-0.54) which was not different than 0.35% (IQR: 0.18-0.54) in the s-KT group ($p=0.78$). KT biopsies with any rejection on both platforms, fifty-one (51/78; 65%) of the biopsies were performed on s-KT and twenty-seven (27/78; 35%) were performed on r-KT. The major indication for biopsy in each group was surveillance (s-KT 30/51; 59% vs r-KT 22/27; 81%). The median dd-cfDNA in the r-KT group was 1.5% (IQR: 0.91-2.0) which was not different than 2.1% (IQR: 0.86-3.3) in the s-KT group ($p=0.27$). KT biopsies with only ABMR by

both histology and MMDx, thirty-four (34/53; 64%) of the biopsies were performed on s-KT and nineteen (19/53; 36%) were on r-KT. The main indication for biopsy in each group was surveillance (s-KT 25/34; 74% vs r-KT 16/19; 84%) The median dd-cfDNA in the r-KT group was 1.5% (IQR: 0.86-2.0) which was not different than 2.0% (IQR: 0.86-3.6) in the s-KT group (p=0.57).

Conclusions: Here we report that there is no difference in dd-cfDNA in recipients s-KT versus r-KT in the setting of no rejection, any rejection or isolated ABMR confirmed by both by histology and molecular signature. We were able to increase the precision of the diagnosis with addition of the molecular microscope analysis. We hypothesize that despite presence of a second source of dd-cfDNA, the lack of nephron mass in the failed allograft prevents it from being a clinically significant source of dd-cfDNA. Further studies will allow this noninvasive biomarker of allograft injury to be used in the ever growing regraft patient population that are commonly sensitized and hence subjected to invasive surveillance biopsies.

Abstract# 657

Dysregulation of Immune Cell Glycolysis and Oxidative Phosphorylation Correlates with Development of Pre-liver Transplant Immune Dysfunction and Post-transplant Mortality

G. Panayotova[1], L. Jin[1], A. Lemenze[1], S. Simonishvili[1], Y. Qin[1], L. Minze[2], G. Dikdan[1], F. Paterno[1], X. C. Li[2], M. Ghobrial[2], J. V. Guarrera[1], K. E. Lunsford[1], *[1]Transplant Surgery, Rutgers NJMS, Newark, NJ, [2]Transplant Surgery, Houston Methodist Hospital, Houston, TX*

Purpose: Cirrhosis-related immune dysfunction contributes to early morbidity and mortality following liver transplant (LT). We have previously identified a pre-LT biomarker panel, the immune frailty index (IFI), which accurately stratifies patients at high risk for post-transplant morbidity and mortality due to immune dysfunction. Prior work shows that impaired immune cell differentiation is central to this process. Here, we evaluate the genetic mechanisms responsible for these immunophenotypic alterations.

Methods: IFI was calculated from pre-transplant HCV viremia, Eotaxin, MMP3, and Fractalkine. Pts with low IFI (Score 0-2) have a 95.5% 1yr survival compared with 46.2% for high IFI (Score 3-4). IFI-high were matched 1:2 with IFI-low based on age, sex, and cause of liver disease and were compared to healthy controls (NHC). RNA-seq was performed on PBMCs (d-1) and gene expression was used for principal component analysis (PCA) and clustering.

Results: Gene expression analysis was performed on 22 LT recipients (n=7 IFI-high, n=15 IFI-low) and 8 NHCs. Donor and recipient characteristics were similar between groups. IFI-high had more positive cultures within 1yr post-op (4 vs 1, p<0.01) and lower 2yr survival (56% vs 100%, p<0.01). PCA analysis demonstrated 4 patterns of gene expression (clusters 1, 2, 3, and 4) with IFI-high predominantly in cluster 3; NHCs grouped together (cluster 5), **Figure 1.** Four patients died during median follow up of two years, all within the IFI-high cohort. Among these, 3/4 (75%) died secondary to infection-related complications (i.e. immune dysfunction), all in cluster 3. Gene analysis revealed mitochondrial function and oxidative phosphorylation genes were comparatively upregulated and glycolysis was comparatively down-regulated in this patient group.

Conclusions: Pre-transplant immune dysfunction in LT recipients is associated with significant alterations in immune cell metabolic pathways, including oxidative phosphorylation and glycolysis. Such metabolic dysregulation is known to abrogate immune cell differentiation into functional effectors. These alteration may direct immune frailty and increase LT recipients' susceptibility to complications and death. Further evaluation of these pathways may offer a potential novel target to interrupt pre-transplant immune dysfunction and improve LT outcomes.

Abstract# 658

Kidney Graft Biopsy for Indication Proteinuria: Finding, and Outcomes

S. Parajuli, K. Swanson, J. Alstott, F. Aziz, N. Garg, W. Zhong, A. Djamali, D. Mandelbrot, *University of Wisconsin, Madison, WI*

Purpose: Proteinuria is common in kidney transplant recipients (KTRs), and is associated with an increased risk of graft failure. A rise in serum creatinine (SCr) is the most common indication for kidney graft biopsies. But there is limited information about biopsy findings and outcomes when the indication for biopsy is isolated proteinuria with stable Scr in KTRs.

Methods: We analyzed all KTRs who underwent biopsy for isolated proteinuria with stable SCr between 01/2016 and 06/2020. Protocol biopsies and biopsy for other indications (research, guided by DSA etc) were excluded. Patients were divided into two groups based on the biopsy findings, Active Rejection (AR) and Other. We defined new proteinuria as urine protein to SCr ratio (UPC) > 0.5 gm/gm and worsening proteinuria as UPC doubled and more than 1. Risk factors for the AR and graft survival were outcomes of interest.

Results: A total of 130 KTRs fulfilled our selection criteria;38 (29%) were in the AR group and 92 in the Other group. Most baseline characteristics were similar between the groups, including indication for biopsy as worsening or new proteinuria. The mean interval from transplant to biopsy in the AR group was 9.1±6. compared to 7.4±6.3 years (p=0.17) in the Other group. SCr, eGFR, and UPC at the time of biopsy were also similar between the groups. Not surprisingly, microvascular inflammation, tubulitis, and sum chronicity scores were higher in the AR group. In multivariate analysis (MV) model 1, only higher HLA mismatch (HR: 1.30; 95% CI: 1.06-1.59; p=0.01) was associated with AR and in model 2, male gender (HR: 0.45; 95% CI 0.23-0.89; p=0.02) was associated with a lower risk for AR. The degree of proteinuria was not associated with AR in either model. At last follow-up, 18% of grafts failed in the AR group (11% death censored), and 17% in the Other group (9% death censored) without significant difference. This was further confirmed by the K-M analysis.

Conclusions: 29% of the patients were diagnosed with AR exclusively based on the proteinuria. Likely due to the early diagnosis without a significant rise in SCr, outcomes were similar in the rejection group compared to the Other group. Routine monitoring for proteinuria in KTRs followed by a biopsy for worsening or new proteinuria may help to identify early rejection.

Abstract# 659

Initial Experience with Trugraf™ Gene Expression Profile and Trac™ Dd-cfdna Testing in Kidney Transplant Recipients Suggests Synergy and Enhanced Management within the First Year Post-transplant and Beyond

V. Paramasivam, B. Greco, M. Germain, *Nephrology, Baystate Medical Center, Springfield, MA*

Purpose: Non-invasive validated rejection biomarkers are now available to monitor kidney transplant patients (KTRs). Two such biomarkers are; TruGraf™ (TG) gene expression profile validated to rule out subclinical acute rejection(subAR) and TRAC™ (donor derived cell free DNA) as a marker of allograft injury in KTRs. The purpose of this study is to describe the initial single center experience of TruGraf GEP and TRAC dd-cfDNA surveillance for KTR within the first year post-txp and greater than one year post-txp. Our program has done 3 and 12 month protocol biopsies for many years. We have now replaced biopsies with biomarker surveillance.

Methods: TG and TRAC was done in all KTRs at 3 and 12 months post-txp. Additionally, all patients being followed by this nephrology group (total n=170) are to be tested once post-txp to determine baseline status (immune quiescence). A positive TG and/or TRAC prompted further evaluation including focused lab review. Biopsies were done only in cases where there was equipoise. Donor specific antibodies (DSA) were done in all patients.

Results: To date, 55 KTRs have been surveilled with TG and/or TRAC; total of 72 TG and 47 TRAC. 9 of 10 new transplants were spared 3 month biopsies, the one biopsy was for DGF; was normal and had a negative TG. An additional 14 were tested one year post tx and 11 of them avoided one year protocol biopsy. A total of 31 patients were tested at > one year post tx. Overall, a total of 2 episodes of subAR were identified. Table 1 and Table 2 showsresults of TG and TRAC testing in lieu of 3 month and 1 year protocol biopsy. Table 3 shows testing concordance. 49% (23/47) confirmed in immune quiescence (rule out subAR) with no allograft injury (GEP negative, dd-cfDNA negative). 5% had positive GEP and dd-cfDNA prompting biopsy and diagnosis (DX) and/or treatment of subAR. The remaining 46% had either GEP or dd-cfDNA positive, prompting further clinical evaluation and correlation with other findings such as DSA, proteinuria, and renal function.

Conclusions: Non-invasive TruGraf GEP surveillance with synergy from TRAC dd-cfDNA ruling out allograft injury spared unnecessary protocol biopsies in KTR at 3 months and provided enhanced surveillance at 12 months and further post-txp, assuring adequacy of immunosuppression and ruling out subAR. Combined TruGraf GEP and TRAC dd-cfDNA is promising, warranting larger studies to determine the optimal synergy with serial testing, especially beyond the first year post-txp where KTR continue to be at risk for subAR

Concordance between TG and TRAC in all tests		
KTRs with both GEP/dd-cfDNA (n=47)	TruGraf GEP negative (TX)	TruGraf GEP positive (not-TX)
TRAC dd-cfDNA negative	23	11
TRAC dd-cfDNA positive	11	2

Abstract# 660

Blood Gene Expression and Donor-derived Cell Free DNA for Diagnosing Subclinical Acute Rejection in Stable Kidney Transplant Recipients

S. Park[1], K. Guo[2], H. Raymond[3], E. Poggio[4], D. Taber[5], C. Marsh[6], S. Kurian[7], S. Kleiboeker[8], J. Weems[8], J. Holman[9], L. Zhao[2], R. Sinha[8], S. Brietigam[2], C. Rebello[2], M. Abecassis[10], J. Friedewald[1], *[1]Transplant Nephrology, Northwestern University, Chicago, IL, [2]Feinberg School of Medicine, Northwestern University, Chicago, IL, [3]Mayo Clinic College of Medicine and Science, Phoenix, AZ, [4]Department of Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH, [5]Division of Transplant Surgery, Medical University of South Carolina, Charleston, SC, [6]Department of Medicine and Surgery, Scripps Clinic and Green Hospital, La Jolla, CA, [7]Scripps Health, La Jolla, CA, [8]Eurofins US Clinical Diagnostics, Lee's Summit, MO, [9]Transplant Genomics, Inc, Mansfield, MA, [10]University of Arizona College of Medicine, Tucson, AZ*

Purpose: A blood gene expression profile (GEP) has been established as a non-invasive screen for subclinical acute rejection (subAR). For patients with allograft dysfunction, donor-derived cell-free DNA (dd-cfDNA) has been used for acute rejection detection but not been studied extensively in patients with stable renal function. We hypothesized that we could improve diagnostic performance for subAR by combining a dd-cfDNA assay with a GEP assay.

Methods: The study cohort consisted of 208 subjects with stable kidney function from a previously reported prospective, multicenter study. 429 blood samples were paired with surveillance biopsies. A GEP assay was performed using a DNA microarray-based gene expression. The dd-cfDNA results were reported as a proportion of the dd-cfDNA over a total cfDNA. We evaluated the diagnostic performance using the area under the receiver operating characteristic (AUC) on GEP and dd-cfDNA alone, and logistic regression with combination of the two tests.

Results: Of 429 samples, 346 (80.7%) and 83 (19.3%) were diagnosed by histologic phenotype as no-rejection and subAR, respectively. The 83 subAR samples consisted of borderline 61.4% (n=51), Banff 1A 6% (n=5), and antibody-mediated rejection (AMR) 32.5% (n=27). The AUC of GEP and dd-cfDNA alone were 0.81 and 0.67, respectively. When two tests were combined, the AUC was increased to 0.83 with prevalence-adjusted negative predictive value (NPV) of 0.86 and prevalence-adjusted positive predictive value (PPV) of 0.62 in the training set (Figure 1A). In the testing set, the AUC was similar as 0.83 with prevalence adjusted NPV and PPV, 0.84 and 0.67, respectively (Figure 1B).

Conclusions: A combination of blood-based biomarkers can improve detection for and provide less invasive monitoring of subclinical acute rejection.

Abstract# 661

Immunosuppression Impacts Panel Reactive Antibody Status in Second Solid Organ Transplant Recipients - A Single Center Experience

J. Patel[1], S. Ali[2], M. L. Sanders[1], C. P. Thomas[1], D. Axelrod[1], M. Bilal[3], E. H. Field[3], S. Kuppachi[1], *[1]University of Iowa Hospitals & Clinics, Iowa city, IA, [2]Louis A. Johnson VA Medical Center, Clarksburg, WV, [3]Iowa City VA Health Care System, Iowa city, IA*

Purpose: Patients who require a second solid organ transplantation are significantly disadvantaged due to the event of sensitization due to the first transplant. We hypothesized that patients who remained on immunosuppression (IS) would have lower levels of calculated panel reactive antibodies (cPRA) prior to a second solid organ (kidney or pancreas) transplantation.

Methods: We retrospectively analyzed cPRA levels in kidney transplant (KT) recipients at our center from January 2009 to December 2019 who had previously undergone a non-liver solid organ transplant (SOT). Patients with three or more transplants were excluded. We compared sensitization between those who remained on IS, and those who did not, based on cPRA, using odds ratio (OR) and Chi-square or Fisher's exact test for statistical significance.

Results: A total of 108 patients met the inclusion criteria. 88 had a prior KT, 12 simultaneous kidney-pancreas, 1 pancreas, 2 lung, and 5 heart before receiving their second solid organ transplant. In 44 out of 108 patients (40.7%), IS was continued before a kidney transplant. In 21 out of 44 patients (47.7%), cPRA was less than 20%, compared to 6 out of 64 patients (9.4%) in whom IS was discontinued. Even the percentage of highly sensitized patients (cPRA >80%) was significantly higher in patients who were not on IS (56.2%) compared to those who remained on IS (13.64%). The OR of having cPRA more than 20% was 8.8 (confidence interval 3.15-24.67) in patients who were not on IS. (Chi-square and Fisher exact p-value < .0001).
Conclusions: In our single center analysis, patients who were not on any IS prior to a second solid organ transplant (kidney or pancreas) had a much higher risk of being sensitized compared to patients who were on IS. The number of highly sensitized patients (cPRA >80) was also significantly higher in those who were not on any IS. Additional prospective studies on a large scale are needed to confirm the benefit of the continuation of IS as well as the associated risk with an extended immunocompromised state.

Comparison of cPRA at second transplant in cases continuing verses stopping IS					
cPRA at Second Transplant	**<20 %**	**20-49 %**	**50-80 %**	**>80 %**	Total
IS continued	21	8	9	6	44
IS stopped	6	9	13	36	64
	27	17	22	42	108

Abstract# 662

Continuation of Immunosuppression After the First Renal Allograft Failure Impacts Panel Reactive Antibody Status During Subsequent Renal Transplantation

J. Patel[1], S. Ali[2], M. L. Sanders[3], C. P. Thomas[3], D. Axelrod[3], M. Bilal[4], E. H. Field[4], S. Kuppachi[3], *[1]University of Iowa Hospitals & Clinics, Iowa CIty, IA, [2]Louis A. Johnson VA Medical Center, Clarksburg, WV, [3]University of Iowa Hospitals & Clinics, Iowa City, IA, [4]Iowa City VA Health Care System, Iowa City, IA*

Purpose: The standard of care following renal allograft failure is to discontinue immunosuppression (IS) to limit risks from further IS. We hypothesized that continuation of IS after kidney transplant (KT) allograft failure would prevent worsening of sensitization status as reflected by calculated panel reactive antibodies (cPRA) before second KT.
Methods: We retrospectively analyzed cPRA of KT recipients at our center from January 2009 to December 2019 who had previously undergone KT or simultaneous kidney-pancreas transplantation (KPT). Patients with more than two KT were excluded. We compared sensitization status based on cPRA analysis at the time of first and second KT, between those who remained on IS, and those who did not, using odds risk ratio (OR) and Fisher's exact test for statistical significance.
Results: Out of 47 patients who met the inclusion criteria, 42 had received a prior KT, while 5 patients had prior KPT. In 17 out of 47 patients (36.1%), IS was continued after allograft failure. In 9 out of 17 patients (52.9%), cPRA remained unchanged between the first and second KT. IS was discontinued in 30 out of 47 patients (63.8%). Among these patients, 27 (90%) experienced an increase in their cPRA. The odds of having an increased cPRA at the time of second KT in patients after stopping IS compared to continuing IS was 10.1 (confidence interval 2.2-46.59, Fisher exact p-value = 0.002).
Conclusions: In our single center analysis, the discontinuation of IS after renal allograft failure significantly increased the OR for increased cPRA at the time of a second KT. Prospective, multicenter studies on a larger scale are necessary to confirm these findings as well as study the risks of infection and malignancy with continued IS.

cPRA status at the time of second kidney transplant in cases continuing verses stopping IS			
cPRA at time of second transplant	**Unchanged**	**Increased**	**Total**
IS continued	9	8	17
IS stopped	3	27	30
	12	35	47

Abstract# 663

Donor-Derived Cell-Free DNA Performance Characteristics are Similar for Repeat and Primary Kidney Transplant Recipients

V. R. Peddi[1], S. Akkina[2], S. C. Jordan[3], W. Tian[4], Y. Qazi[5], *[1]California Pacific Medical Center, San Francisco, CA, [2]Loyola University Medical Center, Maywood, IL, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]CareDx, Brisbane, CA, [5]University of Southern California, Los Angeles, CA*

Purpose: Repeat kidney transplants (RKT) represent 12.4% of kidney transplants (KT) (10.9% of all living donor and 13.6% of all deceased donor). Most RKT are performed >5 years following the primary kidney transplant (PKT). Inferior RKT outcomes are identified among patients having experienced graft loss after less than 5 years and are also considered higher immunological risk. Donor-derived cell-free DNA (dd-cfDNA) has established utility in diagnosing the probability of active rejection in PKTs, however utility in RKTs published in two small series - Mehta, *et al.* (N=12 RKT) from the Diagnosing Acute Rejection in Kidney Transplant Recipients (DART study; ClinicalTrials.gov Identifier: NCT02424227) that demonstrated higher dd-cfDNA baseline than PKT; and Sureshkumar, *et al.* (N=12 RKT) whereupon no statistical difference in baseline was reported.
Methods: 753 patients with PKT were compared with 260 RKT recipients, all having surveillance with dd-cfDNA (AlloSure®; CareDx) as part of the KOAR study. The lowest - referred to as baseline - dd-cfDNA levels within the first year of transplant were examined. The cohort included patients from both surveillance and clinical for cause testing as well as biopsy schedules.
Results: The median baseline AlloSure dd-cfDNA for PKT was 0.20% (mean: 0.27%, variance:0.05), for RKT median was 0.19% (mean:0.35%, variance:0.24) with no significant difference (p = 0.66 with balanced sampling between groups) [**FIGURE 1**]. For the subset of patients who had an allograft rejection - PKT (n=80) and RKT (n=14) - a shift was observed in the mean baseline levels. For PKT and RKT it was 0.34% (variance:0.18) and 0.72% (variance:1.19), respectively (p = 0.35). In this cohort, elevated dd-cfDNA levels were observed at the time of the event. A median of 0.5% (mean: 1.06%, variance:3.05) was observed in PKT compared to median of 0.8% (mean:1.47%, variance:2.58) in RKT [**FIGURE 2**]. The observed differential trend was not statistically significant (p=0.503).

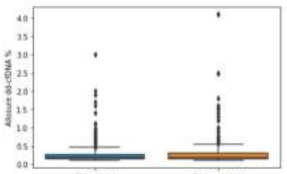

Figure 1: Baseline AlloSure dd-cfDNA levels

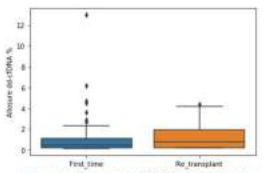

Figure 2: Elevation of dd-cfDNA in Rejection

Conclusions: RKT have equivalent baseline and dd-cfDNA elevations during allograft injury and rejection events as those observed with PKT. The similar performance characteristics of dd-cfDNA in RKT should support utility of this surveillance tool in the repeat kidney transplant population.

Abstract# 664

The Role of the B2 Microglobulin Trend in Patients with Delayed Graft Function After Kidney Transplant

A. Perez-Gutierrez, P. J. Bachul, B. Juengel, P. Witkowski, D. DiSabato, R. Barth, J. Fung, Y. Becker, *Surgery, University of Chicago, Chicago, IL*

Purpose: Delayed graft function (DGF) is associated with worse short and long-term outcomes after kidney transplantation. There is a lack of biomarkers to predict outcomes in patients with DGF. Serum β2 microglobulin is a low-molecular-weight protein. It strongly correlates with serum cystatin C and creatinine; with the advantage of measuring residual renal in dialysis patients. In kidney transplant patients predicts cardiovascular events, overall mortality and graft failure. The role of the β2 microglobulin trend in patients with DGF has not been explored.

Methods: This is a retrospective study of all kidney transplants from deceased donors at our institution from 2014 to 2017. Pediatric and multiple organ transplants were excluded. Only patients with serum levels of β2 microglobulin (postoperative day 1 to 5) were included. β2 microglobulin trend was defined as the difference between β2 on postoperative day four and β2 on postoperative day one. We used univariate and multivariate logistic regression models with level of significance of α=0.05.
Results: A total of 150 kidney recipients were reviewed, 68 (45%) had delayed graft function (median 7.5 days, 1 - 51); 50% of the patients with DGF received dialysis for one week only. Three patients had primary non function. The demographic and clinical characteristics of the patients with and without DGF are shown in tables 1 and 2. β2 microglobulin strongly correlated with the presence of DGF ($p<0.001$) and significantly correlated with eGFR at 1, 6 and 12 months in all patients ($p<0.05$). In DGF group, β2 microglobulin trend correlated with the duration of DGF with p=0.05 (95% CI 0.004 - 6.66). This was independent of donors after circulatory death and type of kidney storage. In our cohort, β2 microglobulin was not associated with mortality or rejection.
Conclusions: The β2 microglobulin trend is a marker of kidney function useful particularly in patients with DGF, because measures the residual kidney function in the setting of dialysis. Following the trend of β2 microglobulin in patients with DGF is informative about the duration of the DGF and may help to make clinical decisions. Validation of this marker in a larger population of patients with DGF is needed.

Table 1. Patients characteristics

	Without DGF, N=82	With DGF, N=68
Age (median)	52.7	53.1
Male	61%	68%
African American	72%	74%
BMI (median)	27.5	27.6

Abstract# 665

Does the Timing of Subclinical Acute Rejection After Kidney Transplant Matter?

P. Portocarrero[1], S. Park[2], K. Guo[3], L. Zhao[3], J. Friedewald[2], *[1]Nephrology, Northwestern University, Chicago, IL, [2]Transplant Nephrology, Northwestern University, Chicago, IL, [3]Feinberg School of Medicine, Northwestern University, Chicago, IL*

Purpose: We hypothesized that the timing of subclinical acute rejection (subAR) diagnosed with biopsy, gene expression profile or donor-derived cell-free DNA is associated with poor graft outcomes.
Methods: The surveillance biopsy samples from a previously selected cohort were paired with a gene expression profile (GEP) and a donor-derived cell-free DNA (dd-cfDNA) results. 2- year composite endpoints (2Y-CCE) were defined as 1) any evidence of ≥ Banff grade II IFTA at 24-month biopsy, 2) biopsy-proven rejection on "for-cause biopsy," 3) a decrease in estimated glomerular infiltration rate (eGFR) by >10 m/min/1.3m^2. We used logistic regression to analyze the timing of subAR (histology, GEP, dd-cfDNA) and 2Y-CCE.
Results: 349 samples were studied (histology, GEP, dd-cfDNA), derived from 161 subjects. Of 161 subjects, 70 reached the 2Y-CCE. SubAR within 6 months post-transplant by histology was significantly associated with more 2Y-CCE than the no rejection group (odds ratio [OR] 4.25, 95% CI 1.04-17.36, p=0.04). Patients with biopsy-proven subAR within 12 months did not associate with 2Y- CCE (OR 2.08, 95% CI 1-4.35, p=0.052). SubAR by GEP at 12 months (OR 2.81, 95% CI 1.11 - 7.09, p=0.03) was associated with 2 Y-CCE. We found that subAR diagnosed with dd-cfDNA within 6 months and 12 months was not associated with 2Y-CCE. However, any positive GEP (OR 2.23, 95% confidence interval [CI] 1.16-4.29, p=0.02) or dd-cfDNA (OR 2.25, 95% CI 1.04 - 4.84, p=0.04) for subAR within the first 12 months were significantly associated with 2Y-CCE as the sample size increased (Table 1).
Conclusions: We found that subAR diagnosed by GEP and dd-cfDNA at different times post kidney transplant was associated with poor graft outcomes. Further protocols using early genetic and serologic markers of subAR need to be established in post-transplant follow-up.

Table 1) Association of SubAR within 6 months, at 12 months, or within 12-months post-transplant by a GEP, dd-cfDNA, and histology with 2Y-CCE

Time of SubAR post-transplant	Histology OR (95% CI, p value)	GEP OR (95% CI, p value)	dd-cfDNA OR (95% CI, p value)
Within 6 M	4.25 (1.04 -17.36, p=0.04*)	1.80 (0.71 - 4.57, p=0.22)	2.33 (0.80 - 6.76, p=0.12)
At 12M	1.60 (0.63 - 4.05, p=0.32)	2.81(1.11 - 7.09, p=0.03*)	2.17 (0.72 - 6.57, p=0.17)
6 M or 12 M	2.08 (1 - 4.35, p= 0.052)	2.23 (1.16 - 4.29, p= 0.02*)	2.25 (1.04 - 4.84, p=0.04*)

Abstract# 666

GENiE in a Bottle - Renasight Testing in the Kidney Transplant Setting - A Single Center Experience

Y. A. Qazi[1], W. Mon[1], N. Ioannou[2], M. Smogorzewski[1], *[1]Keck Medical Center at USC, Los Angeles, CA, [2]Natera, San Carlos, CA*

Purpose: Renasight™(Natera), a recently available genetic test provides analysis on 382 genes associated with adult-onset kidney disease, covering clinical categories (cystic, tubular, glomerular, complement-related, congenital disorders,and nephrolithiasis).The purpose of our study was to perform genetic testing on ESRD patients in the transplant setting- to diagnose, confirm or reclassify the etiology of ESRD and to determine if the testing impacted management.
Methods: Renasight testing has been used at our center in the pre and post-transplant settings since spring 2020. Following were the criteria used to test individuals for Renasight: Family history of ESRD, atypical presentations of ESRD, young individuals with ESRD of unclear etiology.
Results: 50 patients have been tested, 32 resulted and 18 still pending. 17/32 (53%) had some genes identified during testing while 15/32(46 %) had none. 8/17 were identified as positive ; 1 Alport's syndrome with ADMATS 13 mutation, 2 Alport's,1 PKD with Jouberts, Bardet BIedel, Meckel, Senior Loken syndrome, 1 with HNF 4A with Fanconi's syndrome, MODY Type1, Apol1, 1 renal agenesis/RET, 1 with 2 with ApoL 1. 9/18 patients had variants of unknown significance genes (VUS) including NPHS2 Nephrotic Syndrome, Type 2 /Short-Rib Thoracic Dysplasia Complement Factor I Deficiency, Familial Mediterranean Fever, PRODH Hyperprolinemia Type 1, Cystinosis. Genetic testing altered management as follows; 3 with Col4 A gene abnormalities were referred to other specialists, testing of anti GBM ab and informing family members who had donated in the past. 1 patient is being observed for complement activation conditions, 1 patient is being worked up for hylerprolinenia 1 for cystinosis. 1with RET gene abnormality is being worked up for MEN2 syndrome, 1 for amyloid, 1 with pre transplant MODY type 1 variant for Diabetes.
Conclusions: Renasight testing in the kidney transplant setting can confirm or identify the pre transplant diagnosis of ESRD when etiology is unclear or biopsies are unavailable, initiate appropriate referrals and facilitate appropriate therapeutic interventions . It can also facilitates early diagnosis of familial conditions,allowing families to intervene early and be better educated on organ donation. Renasight testing influenced diagnosis and management in our study Prospective data is being collected.

Abstract# 667

Role of Trugraf Testing in Kidney Allografts Previously Biopsied for Dysfunction

Y. A. Qazi[1], W. Mon[1], C. Choi[1], S. Qazi[2], M. Smogorzewski[1], *[1]Keck Medical Center at USC, Los Angeles, CA, [2]Keck Medical Center at USC, La Canada Flt, CA*

Purpose: TruGraf®, can be used as an alternative to surveillance biopsies for ruling out "silent" subclinical acute rejections in transplant patients with stable graft function. However, its role in patients with graft dysfunction is unclear. The purpose of our study was to analyze the significance of Trugraf testing in kidney transplant previously biopsied for allograft dysfunction.

Methods: Serum creatinines of kidney transplant recipients who had previously undergone a for cause allograft biopsy and subsequent Trugraf were analyzed. The patient's were divided into four groups based on BPAR and Trugraf result: 1.BPAR+/NotTx, 2.BPAR-/NonTx , 3.BPAR-/Tx, 4. BPAR-/Tx-

Results: 23 patients who had undergone a kidney transplant biopsy for allograft dysfunction followed by a subsequent Trugraf test were analyzed. Donor type: 4 LTx and 19 DDTx, Avg. Mismatches; 5.03(1-6mm), Induction I/S; rATG 21, Simulect 2, mean duration between the biopsy and trugraf testing; 9.21 months (1-43 months). The number of BPAR+=15, BPAR- = 7, Not Tx = 12 and Tx were 11. The mean serum Cr for BPAR+/NotTx, BPAR-/NonTx , BPAR-/Tx, BPAR-/Tx- were 2.25 mg/dl(1.8-2.7 mg/dl), 1.90 mg/dl(1.2-3.34 mg/dl), 1.36 mg/dl(0.65mg/dl-2.43 mg/dl), 1.14 mg/dl(0.92-1.29mg/dl).

Conclusions: In this small observational study of allografts previously biopsied for dysfunction, the renal function was worse for allografts with previous BPAR and a subsequent NonTx Trugraf results and best in allografts with no BPAR and a Tx Trugraf. Trugraf surveillance of allografts with previous history of dysfunction may help to identify and stratify ones at a higher risk of deteriorating renal function. More data is being collected prospectively.

Abstract# 668

Tru and Sure -A Tale of Two Cities! Can Allosure Predict and Enhance Trugraf Results?

Y. A. Qazi[1], W. Mon[1], S. Qazi[2], C. Choi[1], M. Smogorzewski[1], *[1]Keck Medical Center at USC, Los Angeles, CA, [2]Keck Medical Center at USC, La Canada Flt, CA*

Purpose: With the introduction of Cell free DNA(cfDNA) technology in transplantation a few years ago, and a more recent addition of genomic testing with TruGraf -surveillance of the renal allograft is moving beyond the serum creatinine. The purpose of our study were two fold- 1. To see if previously performed serial cfDNA levels could predict TruGraf results. 2. To see if collective interpretation of the two tests could help in predicting the overall trend in renal function.

Methods: Kidney transplant recipients who had undergone serial cell-free DNA testing (Allosure) and at least one TruGraf test were enrolled in the study. An Allosure test had to be have been performed within 5 days of the TruGraf. The following were collected ; mean of serial Allosure levels tested prior to Trugraf (cfDbaseln), Allosure on the day of Trugraf testing (cfDTruG), cfDNA change (Chng) [(cFDbaseln)- (cfDTruG)], Trugraf results as NotTX and Tx and the overall trend of renal function(CrTrnd) based on serum creatinines was classified as ;stable(s) , worsening(w) or improving(i).

Results: 10 patients met the inclusion criteria. TruGraft results; 10 Not-Tx and 6 TX. The mean number of cfDNA testing done prior to the TruGraf test was Not-Tx 4 (1-6) and 4.6 for the Tx (2-9). The mean **cfDbaseln** ; Not-Tx :0.54% (0.13%-1.5%) vs TX: 1.39%(0.37%-3%), the mean **cfDTruG** ; Not-Tx :0.68% (0.12% to 2.7%) vs Tx 1.25% (0.26%-4.8%) , mean **Chng;** Not-Tx : -0.142% (-2.12% to 0.68%) vs Tx 0.14%(-1.8% to 1.93%), **CrTrnd ; Not-Tx:** 1 **s,** 7 **w**, 2 **i** vs Tx: **s 4**, **w 0** ,**i** 2.

Conclusions: In our small observational study, it appears that serial cell-free DNA may not predict the outcome of TruGraf results, and that when used together provide complimentary insights into grafts at higher risk of deteriorating renal function. Our study suggests that cfDNA is likely most meaningful when interpreted in the context of change from a baseline. A rise of cfDNA from baseline accompanied with a Non-tx TruGraf result was associated with graft instability. Current ongoing prospective registry studies may confirm our observations. Whether the mechanistic differences in injury account for these observations and can be validated by molecular microscopy remains undetermined.

Abstract# 669

Core Signature of Rejection-Specific Cytokines and Chemokines in Heart Biopsies After Transplantation

L. M. Radomsky[1], Y. Scheibner[2], J. F. Kuehne[1], J. Keil[1], K. Beushausen[1], K. Ludmilla[2], A. Schick[2], F. Ius[2], G. Warnecke[3], C. Bara[2], C. S. Falk[1], *[1]Institute of Transplant Immunology, Hannover Medical School, Hannover, Germany, [2]Department of Cardiothoracic, Transplantation and Vascular Surgery, Hannover Medical School, Hannover, Germany, [3]Clinic for Cardiac Surgery, University of Heidelberg, Heidelberg, Germany*

Purpose: Allograft rejection remains one of the limiting factors for survival after HTX. The aim of this project was to characterize the cytokine/chemokine network in heart biopsies and peripheral blood plasma after TX. The quantified cytokine/chemokine concentrations could reflect the ischemia/reperfusion response as well as rejection status of the allograft. Therefore we hypothesize that in heart biopsies with histopathological proven rejection the microenvironment is significantly altered and potentially specific cytokine/chemokine patterns could predict allograft rejection.

Methods: Heart biopsies (N=181 biopsies; 52 patients) and peripheral blood samples (N=35 patients) were obtained at different time points after HTX. Using luminex-based multiplex assays 50 cytokines/chemokines in tissue lysates and peripheral blood plasma were quantified. Concentrations of samples with rejection and no-rejection were compared in lysates and plasma. Moreover correlation of tissue and plasma levels and comparison of cold static versus normothermic machine preservation were performed.

Results: With regard to the rejection status we identified significant differences in lysate concentrations. Especially CXCL9/MIG, CXCL4/MIP-1β and CXCL10/IP-10 showed significantly elevated concentrations in biopsies with proven rejection ($p<0.001$). In addition, we identified individual long-term changes of single patients after transplantation and significant differences comparing tissue lysates with plasma concentrations. Interestingly, we found no strong correlation between plasma and lysate concentrations. Moreover significantly elevated concentrations of MIF, M-CSF, FGF basic and ICAM-1 ($p<0.05$) in the first biopsies after HTX were found by comparing cold static preservation and normothermic machine perfusion.

Conclusions: We could detect a core signature for biopsies with pathologically secured rejection consisting of increased concentrations of the chemokines CXCL9/MIG, CXCL3/ MIP-1α, CXCL4/MIP-1β and CXCL10/IP-10. This signature is clearly distinguished from the pattern of the ischemia/reperfusion response (i.e. elevated levels of IL-6, CXCL8, IL-10) suggesting differences in the underlying inflammatory mechanisms. Importantly, since there was no correlation between the measured protein concentrations in plasma and tissue lysates, biopsies remain indispensable for the diagnosis of heart rejection.

Abstract# 670

Analysis of Single Cell RNA Sequencing Data to Define Biomarkers of Human Liver Immune Tolerance

B. Rocque[1], A. Barbetta[1], P. Singh[1], C. Goldbeck[1], D. G. Helou[2], E. Loh[3], N. Ung[4], J. S. Lee[4], O. Akbari[2], J. Emamaullee[1], *[1]Surgery, University of Southern California Keck School of Medicine, Los Angeles, CA, [2]Molecular Microbiology and Immunology, University of Southern California, Los Angeles, CA, [3]Norris Medical Library, University of Southern California Keck School of Medicine, Los Angeles, CA, [4]Ellison Institute, University of Southern California, Los Angeles, CA*

Purpose: The liver is unique in its ability to maintain immune homeostasis and promote operational tolerance following solid organ transplantation. Single-cell RNA sequencing (scRNA seq) is a powerful approach to generate highly dimensional transcriptome data to understand cellular phenotypes. However, when scRNA data is produced by different groups, with different data models, different standards, and samples processed in different ways, it can be extremely challenging to draw meaningful conclusions from the aggregated data. The goal of this study was to establish a method to combine 'human liver' scRNA seq datasets by 1. characterizing the heterogeneity between studies and 2. using the meta-dataset to define the immunotolerant phenotypes across immune cell subpopulations in healthy human liver.

Methods: Publicly available scRNA seq data generated from liver samples obtained from a combined total of 17 patients were analyzed. Liver-specific immune cells (CD45+) were extracted from each dataset, and immune cell subpopulations (myeloid cells, NK and T cells, plasma cells, and B cells) were examined using dimensionality reduction (UMAP), differential gene expression, and ingenuity pathway analysis.

Results: All datasets co-clustered, but cell proportions differed across studies. Gene expression correlation demonstrated similarity across all studies, and canonical pathways that differed between datasets were related to cell stress and oxidative phosphorylation rather than immune-related function. Detailed analysis of differential gene expression identified concordant gene signatures for each hepatic immune

subpopulation (Fig 1). Expression levels across all immune cellular functions including immune response, activation, phagocytosis and adhesion were globally low indicating a tolerogenic state.

Conclusions: This method for meta-analysis of scRNA sequencing datasets provides a novel approach to define the features of immune homeostasis in human liver. Pathways and cellular phenotypes involved in liver immune cell tolerance provide a critical reference point as clinical tolerance strategies are explored in liver transplant recipients.

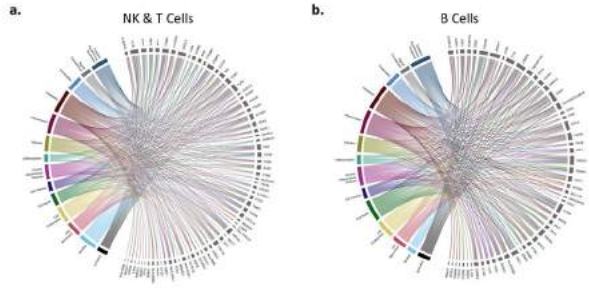

Figure 1. Chord diagrams demonstrating the overlap between differentially expressed genes for each cellular function across NK and T (A) and B-cell (B) phenotypes in healthy human liver.

Abstract# 671

Kidney Injury in Hematopoietic Cell Transplant (HCT) Recipients: Urinary Biomarkers to the Rescue

T. Salinas[1], C. Snopkowski[1], C. Li[1], K. Chen[1], M. Lubetzky[1], S. Salvatore[1], K. Van Besien[1], E. Jaimes[2], S. Hingorani[3], S. Seshan[1], T. Muthukumar[1], *[1]NY Presbyterian- Weill Cornell Medical College, New York, NY, [2]Memorial Sloan Kettering Cancer Center, New York, NY, [3]University of Washington School of Medicine, Seattle, WA*

Purpose: Kidney injury is common in HCT recipients and can be the result of graft versus host/kidney disease. However, this has not been well characterized, mainly due to limitations in performing kidney biopsies in these patients. Alloimmune injury in solid organ transplants is a host versus graft disease whereas in HCT is a graft versus host disease. Urinary cell mRNA has been validated as a noninvasive biomarker for the diagnosis of acute rejection in kidney transplant recipients. In an analogous fashion, urinary biomarkers may help in the noninvasive diagnosis of native kidney injury in HCT recipients.

Methods: We obtained urine samples from 9 HCT recipients: 3 with acute kidney injury (AKI) and native kidney biopsy showing tubulitis and interstitial inflammation (Figure 1), 2 with AKI that resolved spontaneously, and 4 with normal kidney function. We also obtained urine samples from 40 kidney allograft recipients: (i) 20 with biopsy diagnosis of acute cellular rejection (ACR) and (ii) 20 with stable graft function and normal/no rejection biopsies. We isolated total RNA from urinary cells, reverse transcribed to cDNA, and measured the absolute quantity of mRNA level of CXCL10 (chemokine) and CD3e (T cell marker), and 18S rRNA by qRT-PCR assay. We calculated the CTOT-04 urinary cell mRNA signature score for each recipient (Suthanthiran et al, N Engl J Med 2013).

Results: Of the 3 HCT recipients with AKI who had a kidney biopsy, 2 had significant inflammation that stained positive for CD3 and/or Granzyme B in the interstitium and tubules (Figure 1). The urinary cell CTOT-04 signature score was higher in HCT recipients with AKI/tubulitis and interstitial inflammation in the native kidney and resembled ACR of kidney allograft recipients (Figure 2).

Conclusions: We herein confirm our hypothesis and demonstrate the feasibility and utility of urinary cell molecular profiling as a noninvasive tool for the diagnosis of kidney injury in recipients of HCT.

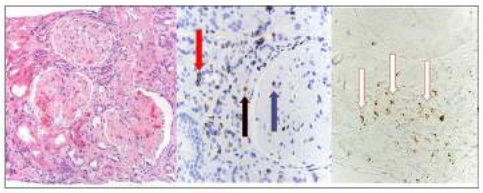

Figure 1. Kidney biopsy of a HCT recipient with systemic graft versus host disease and acute kidney injury showing inflammation and tubulitis (left panel). The inflammatory infiltrate was predominantly comprised of CD3+ T cells (middle panel) causing tubulitis (red arrow), interstitial inflammation (black arrow), and glomerulitis (blue arrow). Granzyme B+ cytotoxic T cells were abundant (right panel, white arrows). Alloimmune injury in solid organ transplants is a host versus graft disease whereas in HCT is a graft versus host disease. Histology of this native kidney biopsy in an HCT recipient resembles acute rejection in kidney transplant recipients, providing a strong rationale for testing the hypothesis that urinary biomarkers may similarly help in the noninvasive differential diagnosis of native kidney injury in HCT recipients.

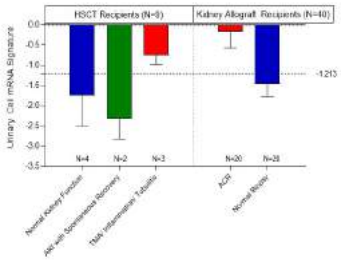

Figure 2. Urinary cell mRNA signature score (mean±SE) in HCT recipients and kidney transplant recipients. CTOT-04 urinary cell mRNA signature score (Suthanthiran et al., N Engl J Med 2013) was calculated by measuring the absolute quantity of mRNA level of CXCL10 (chemokine) and CD3e (T cell marker), and 18S rRNA by qRT-PCR assay. Urine samples were obtained from HCT recipients (N=9) and kidney transplant recipients (N=40). The dotted line represents the cut point value (-1.213) for the diagnosis of ACR in kidney transplant recipients.

Abstract# 672

Nonadherence Post-kidney Transplant is Associated with Increased Immune Activation Detected by Peripheral Blood Gene Expression Assay

N. Singh[1], A. Palermini[1], M. S. Naseer[1], T. Le[1], S. Tandukar[1], D. Aultman[2], H. Shokouh-Amiri[2], G. Zibari[2], *[1]Transplant, John C. McDonald Regional Transplant Center - Willis Knighton Health System, Shreveport, LA, [2]Advanced Surgery, John C. McDonald Regional Transplant Center - Willis Knighton Health System, Shreveport, LA*

Purpose: Nonadherence to immunosuppression medications is common post-transplantation. We hypothesize that nonadherence results in a heightened alloimmune response in kidney transplant recipients (KTRs) which in turn may lead to adverse graft outcomes post-transplant. AlloMap (CareDx®) is a non-invasive peripheral blood gene expression assay associated with genes involved in immune response. Our center has been using cell-free DNA (Allosure; CareDx®) and gene expression assay (AlloMap; CareDx®) for immune monitoring in KTRs enrolled in OKRA registry since Nov 2019.

Methods: We assessed the stable KTRs in the outpatient transplant clinic for self-reported adherence using the Morisky Medication Adherence Scale (MMAS-8), a structured eight-question survey from Sep 15 to Nov 15, 2020. The baseline demographics, number of medications, eGFR, BK viremia, medication side effects, graft rejection, cell-free DNA (Allosure; CareDx®), and gene expression assay (AlloMap; CareDx®) were compared between the non-adherent and adherent patients.

Results: There were no statistically significant differences in baseline demographics (age, gender, and race), BK viremia, time post-transplant, medication side effects, and eGFR at 1-year post-transplant in adherent and non-adherent patients. The non-adherent patients, as compared with adherent patients, were on a lower number of medications (9.26 ± 2.70 vs 11.39 ± 3.79, p = 0.02), had more graft rejection (17.39% vs 15.25%, p = 0.01), and depicted higher AlloMap values on immunosurveillance post-transplant (10.85 ± 2.03 vs 8.05 ± 3.49, p = 0.01) [Table 1].

Table 1: Results			
	Non-adherent (MMAS-8 score ≤6), [n=23]	Adherent (MMAS-8 score ≥7), [n=59]	P-Value
MMAS-8 Score, mean ± SD	5.43 ± 0.79	7.51 ± 0.50	<0.01
Time Post-Transplant (Years), mean ± SD	4.01 ± 4.75	4.12 ± 7.34	0.95
Number of Medications, mean ± SD	9.26 ± 2.70	11.39 ± 3.79	0.02
eGFR (ml/min/1.73m2) at 1-Year Post-Transplant, mean ± SD	53.63 ± 14.25	61.12 ± 21.35	0.19
Graft Rejection, % [n]	17.39 [4]	15.25 [9]	0.01
AlloSure, mean ± SD	0.87 ± 1.18	0.46 ± 0.87	0.07
AlloMap, mean ± SD	10.85 ± 2.03	8.05 ± 3.49	0.01

Conclusions: Nonadherence as measured by MMAS-8 is associated with increased immune activation and a higher risk of graft rejection in KTRs.

Abstract# 673

Trugraf Gene Expression Testing Can Discriminate Rejection in the Setting of Acute Kidney Injury

N. Singh[1], M. S. Naseer[1], D. Aultman[2], H. Shokouh-Amiri[2], G. Zibari[2], *[1]Nephrology, John C. McDonald Regional Transplant Center - Willis Knighton Medical Center, Shreveport, LA, [2]Advanced Surgery, John C. McDonald Regional Transplant Center - Willis Knighton Medical Center, Shreveport, LA*

Purpose: The TruGraf kidney blood gene expression test is a well-validated non-invasive biomarker to detect immune quiescence thus ruling out silent subclinical rejection in stable kidney transplant recipients, eliminating the need for a surveillance biopsy. The TruGraf test is a microarray-based assay that analyzes the peripheral blood gene expression profile (GEP) and provides a binary result of either TX (Transplant eXcellence) or not-TX (not Transplant eXcellence). A TruGraf TX result correlates with a high degree of confidence (NPV 89%) to a surveillance biopsy result showing no evidence of rejection. Given this intended context of use, TruGraf validation was performed exclusively in cohorts of patients that have a stable renal function defined as SCr <2.3 or <20% increase as compared to the average of previous 3 SCr results. The intent of this study was to evaluate performance in the setting of unstable kidney function (AKI) and for-cause biopsies.

Methods: This is a retrospective evaluation of serial TruGraf gene expression testing done on 10 patients with evidence of AKI (SCr >2.3 or >20% increase over the average of previous 3 SCr values). From Dec 2019 to Jun 2020, a total of 23 tests were drawn on these patients as an adjunct to clinical and laboratory assessment.

Results: Of the 23 TruGraf tests done, 13 (56%) were a TX result while 10 (43%) were a not-TX result. There was a total of 11 biopsies done on 9 patients with the majority of biopsies (n=9) being done within 2 weeks of the TruGraf test date. One patient with a TX result did not have a biopsy done during this observation period. The GEP result of TX or Not-TX correlated with biopsy results in 10 of the 11 samples. Of these 10 biopsy results, a TX result was consistent with no rejection on biopsy (n=4). The Not-TX result (n=6) correlated with positive biopsies with histology for borderline rejection (n=1), mixed TCRM/AMR (n=2), AMR (n=2), and TCMR (n=1). In the single sample with a false negative TX result, the patient's biopsy was positive for AMR with C4d2, PTC-. The performance metrics in this patient population were: sensitivity 85.71%, specificity 100%, and accuracy 90.91%.

Conclusions: As expected, the TruGraf GEP analysis is consistent along the continuum of rejection and is inclusive of both subclinical and clinical acute rejection. While limited by a small sample size, the TruGraf test has a high degree of accuracy in the setting of AKI and appears to have stronger performance as compared to the context of stable kidney function.

Abstract# 675

Analysis of the Difference of the Monitoring Results of Tcr High Variable Area in Renal Transplant Recipients After Treatment with Different Immune Induction Schemes

P. Tian, F. Han, M. Dou, B. Zheng, G. Deng, X. Ding, W. Xue, *The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*

Purpose: To observe and summarize the effect of different induction schemes on the highly variable region of T-lymphocyte receptor (TCR) in living relative renal transplant recipients.

Methods: According to the early use of immune-induced antibody, 12 living relative kidney transplant recipients were divided into three groups: baliximab group (BLX group, 4 cases), Rabbit anti human thymus immunoglobulin group (rATG group, 4 cases) and methylprednisolone group (MP group, 4 cases). The immune group library was established to analyze the three days before operation (before administration) and one week, two weeks and one month after operation Blood TCR-CDR3 Clone Diversity, clone frequency, clone change mode and other differences, and through the correlation with the expression of immune related markers, analyze the differences of results in each group and the possible clinical significance.

Results: There were no acute rejection and 2 cases of mild infection in rATG group. The clonal diversity, clonal frequency, clonal change mode and some immune markers of TCR-CDR3 were changed in all groups and groups, especially in rATG group.

Conclusions: The expression profile of TCR-CDR3 in the peripheral blood of recipients showed different expression characteristics after the application of different immune induction schemes, which was related to the change of immune status to a certain extent. It may become a detection method with predictive value for infection or rejection in living relative kidney transplant recipients.

Abstract# 676

Donor Derived Cell-free-dna (dd-cfdna) as a Surrogate Marker for Kidney Biopsy- Indiana University Transplant Nephrology Experience

S. Valavoor[1], A. Sharfuddin[2], G. William[3], M. Yaqub[1], D. Mishler[1], O. Adebiyi[2], *[1]Nephrology, Indiana University, Indianapolis, IN, [2]Transplant Nephrology, Indiana University, Indianapolis, IN, [3]Transplant Surgery, Indiana University, Indianapolis, IN*

Purpose: Patient monitoring after kidney transplantation (KT) for early detection of allograft rejection remains key in preventing allograft loss. Donor-derived cell-free DNA (dd-cfDNA), a noninvasive surrogate for kidney biopsy is now widely used in several kidney transplant in USA in view of the reported ease of early diagnosis of acute rejection as well as avoidance of potential complications associated with kidney biopsy. More importantly, many transplant practitioners now use dd-cfDNA as a noninvasive monitor of immunological status of kidney allografts. Since January 2019, Indiana University transplant program has adopted the use of dd-cfDNA as part of diagnostic tool to evaluate kidney rejection and hereby report our experience.

Methods: Study was a retrospective chart review of patients who received a kidney biopsy and dd-cfDNA as part of diagnostic work up for suspect acute rejection. Adult patients (>18 y/o) who underwent dd-cfDNA and Allogaft biopsy within a time a frame of 2 weeks or less between tests were included. Acute rejection was determined either by pathology has confirmed in report of kidney biopsy or by report of >1 % dd-cfDNA screen. Results were analyzed to correlate the findings on the kidney biopsy with the reports on dd-cfDNA screen.

Results: 29 Patients with suspected rejection who underwent both donor-derived cell-free DNA (dd-cfDNA) met the inclusion criteria. 23 out of 29 patients underwent dd-cfDNA and Allograft biopsy within a time frame of 1 week. Results of our findings are presented in Table 1.

Overall, findings on kidney biopsy and dd-cfDNA report correlated in only 7 out of 29 patients (24%) included in the study. The limitation to our study includes the small sample size and the use of single point dd-cfDNA in acute rejection diagnosis.

Conclusions: Our findings suggest negative dd-cfDNA alone should not be considered to have "rule out" rejection when pre-test probability for rejection is high especially in cases where the pretest probability for rejection is very high. Likewise, serial screen of dd-cfDNA at specific intervals may be a of a better tool either for acute rejection diagnosis or monitoring tool compared to single point screens.

Table 1: Correlation between Kidney Transplant Biopsy and dd-cfDNA report

Groups	Biopsy Rejection	dd-cfDNA Rejection	Number of Patients	Acute Cellular Rejection	Acute Antibody Mediated Rejection
Group 1	Yes	Yes	6	Yes (6 Patients)	Yes (1 patient)
Group 2	Yes	No	17	Yes (17 Patients)	Yes (1 Patient)
Group 3	No	Yes	5	NA	NA
Group 4	No	No	1	NA	NA

REDINREN, Malaga, Spain*

Purpose: Klotho expression is lowered in patients with chronic kidney disease (CKD). After kidney transplant (KT), serum Klotho levels could be significantly increased compared to the level recorded in uremic patients. However, some factors related to KT might reduce serum Klotho levels leading to an early ageing of the organ.The aim of our study was to evaluate serum Klotho levels in early kidney post-trasplantation patients and its relationship to delayed graft function (DGF) and the histologic data at third month post-KT.

Methods: We determined Klotho levels in 15 KT patients at baseline and third month after KT and we performed a protocol biopsy (PB) at third month post-transplant. For the determination of soluble Klotho, peripheral blood was extracted pre-TX and 3 months after KT and serum levels were analyzed by ELISA, using soluble human α-Klotho. PB were assessed following the Banff 2017 Classification and inflammation was defined as the sum of interstitial inflammation (i), tubulitis (t), glomerulitis (g) and arteritis (v) scores.

Results: The recipients were 55.2±14.7 years old on average; 46.7% were men; 93.3% received induction therapy; cold ischemia time was 13.9±2.9 hours and 46.7% had DGF. All the patients were on standard therapy with Tacrolimus, MMF and Prednisone.Soluble Klotho levels decreased significantly from pre-KT to third month post-KT (575.7±263.0 vs 429.1±171.5 pg/ml; p=0,001). 7 patients developed DGF and Klotho levels were considerably lower to those with DGF (575.6±291.5 vs 438.8±189 pg/ml; p=0,06). Soluble Klotho levels at third month after-KT showed a non-significant decrease in patients who had inflammatory graft lesions (i+t+g+v>0) compared to those who did not have inflammatory data (i+t+g+v=0) in PB (355.3±114.7 vs 518±206.2 pg/ml; p=0.078).

Conclusions: Klotho levels decrease significantly at third month post-KT. DGF and subclinical inflammation could contribute to a lower production of klotho by the graft. This could accelerate the senescence of KT in the future term. Long-term follow-up longitudinal studies will clarify these hypotheses

Abstract# 678

Is Subclinical Allograft Rejection by 2019 Banff Criteria Associated with Worse Kidney Allograft Outcomes? Comparison Between 2007 and 2019 Banff Criteria

M. T. Victor[1], S. Park[2], K. Guo[1], L. Zhao[1], J. Friedewald[3], *[1]Feinberg School of Medicine, Northwestern University, Chicago, IL, [2]Transplant Nephrology, Northwestern Univeristy, Chicago, IL, [3]Transplant Nephrology, Northwestern University, Chicago, IL*

Purpose: We hypothesize that Subclinical Acute Rejection (SubAR) under the new Banff 2019 criteria will be more strongly associated with a 2-year composite endpoint (2Y-CCE) than previous criteria.

Methods: SubAR and 2Y-CCE were assessed in a previously studied patient cohort. SubAR was defined as histology on a surveillance biopsy consistent with acute rejection (≥Banff borderline changes and/or antibody-mediated rejection). Transplant excellent (TX) was defined as negative histology for acute rejection. 2Y-CCE was defined as any of the following: evidence of ≥ Banff grade II IFTA at 2-year biopsy, biopsy-proven rejection on "for-cause biopsy," or a decrease in eGFR by >10 m/min/1.73m^2. For logistic regression analysis, subjects were divided into three groups (because subjects had more than one biopsy in the trial) based on biopsy sample classification under 2019 and 2007 criteria: 1) subAR-only, 2) TX-only, 3) subAR and TX (mixed).

Results: 253 unique subjects with 551 biopsy samples were assessed. Of these, 192 subjects with 444 samples had 2Y-CCE results and were eligible for analysis, 1) subAR only (2019 Banff: n=13; 2007 Banff: n=21), 2) TX only (n=141; n=106), 3) mixed (episodes of both subAR and TX) (n=38; n=65) (Figure 1). A total of 82 subjects reached 2Y-CCE under either set of criteria (n=82). 65 borderline samples were reclassified to TX by the 2019 Banff criteria (Table1). The subAR-only group was found to have a significantly higher odds ratio (OR) for developing 2Y-CCE than the TX-only group under both 2007 (OR = 19.27 (95% CI [4.25, 87.42], p =0.001)) and 2019 (OR = 19.33 (CI [2.44, 152.92], p =0.01) Banff criteria. The SubAR only group by 2019 Banff criteria had a slightly stronger association with 2Y-CCE than by 2007 criteria. There was no significant association with developing 2Y-CCE between the TX-only group and the mixed group under 2007 and 2019 Banff criteria.

Conclusions: The subAR only group classified by 2019 Banff criteria, which brought an increase in the diagnostic threshold for borderline changes, showed slightly stronger association with developing 2Y-CCE than by 2007 Banff criteria. The subAR group classified with either criteria are significantly associated with 2Y-CCE compared to the Tx only group. Further investigation is warranted with a larger cohort and longer follow-up to evaluate the impact of the prognostic ability of the new 2019 Banff criteria.

Figure 1) Distribution of patients amongst groups based on biopsy results, for both 2007 and 2019 Banff criteria.

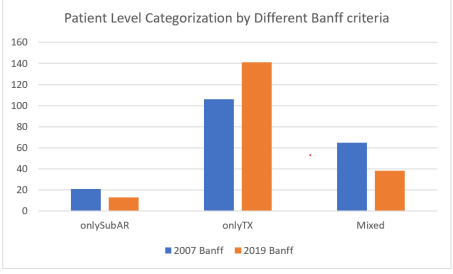

Table 1) Sample level distribution between Banff 2007 and 2019 criteria

	Banff 2007 (n=136)	Banff 2019 (n=71)
Borderline	99 (72.8%)	34 (47.9%)
≥ 1A	7(1A=6, 1B=1) (5.1%)	11 (1A=9, 1B=2) (15.5%)
AMR	30 (22.1%)	26 (36.6%)

Abstract# 679

Long-term Outcomes of Early Steroid Withdrawal (SW) After Kidney Transplant

D. Vock[1], A. Matas[2], [1]*University of Minnesota School of Public Health, Minneapolis, MN,* [2]*University of Minnesota Medical School, Minneapolis, MN*

Purpose: Early SW (<7 days posttransplant) has been associated with minimization of steroid-related side effects and improved cardiovascular risk profile. Yet, in the U.S., only ~30% new kidney tx recipients are treated with early SW due to concern about increased acute rejection rates and long-term outcomes.

Methods: To assess long-term outcomes, 1123 kidney recipients (762 LD; 361 DD) undergoing early SW between 1999 and 2009 at a single center were matched (see Table) using sparse, optimal matching with refined covariate balance constraints - using SRTR data - to recipients at large volume centers receiving maintenance prednisone at hospital discharge (5:1 matching ratio). Graft (GS) and patient (PS) survival were estimated by donor type and steroid group using Kaplan-Meier (KM) estimators, and compared between groups using log-rank tests. Due to small residual imbalances among covariates after matching, we estimated the hazard ratio (HR) of maintenance prednisone vs SW using proportional hazards models adjusting for common recipient, donor, and surgical characteristics.

Results: Median (IQR) followup was 10.3 (5.4 - 13.4) and 7.6 (3.8 - 11.6) years for LD and DD, respectively. By KM, compared to maintenance prednisone, DD receiving SW had significantly better PS throughout 20-yr f/u (adjusted HR, 1.46; 95% CI, 1.18-1.80) (Figure). There was no difference in DD GS, or in LD PS or GS; and no evidence of increased long-term (>10 years) graft failure associated with early SW.

Conclusions: We conclude that early SW has similar or better long-term outcomes than maintenance prednisone.

Table – Groups were matched on:

Recipient	
Age	Race
Gender	Transplant #
Primary disease	Preemptive
Diabetes	BMI
PRA	Cold ischemia time
HLA mm	Transplant year
Donor	
Age	Race
Gender	Hypertension
Creatinine	Cause of death
Donation after circulatory death	
Immunosuppression	
Induction	Maintenance

Figure – Patient and graft survival: Maintenance prednisone vs discontinuation

Identification and Validation of a Prognostic Index for Renal Allograft Survival Based on the Geo Database

X. Zhang, Z. Wang, Z. Han, J. Tao, X. Ju, R. Tan, M. Gu, *The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Purpose: Chronic allograft injury (CAI) following kidney transplantation is still a threat to the allograft long-term survival. This study was designed to explore and analyze the data extracted from GEO (Gene Expression Omnibus) database and sort out the identification of allograft prognosis of kidney tranplanted patients by transcriptome.

Methods: Three high quality arrays from GEO database, GSE25902 (n =24), GSE57387 (n =86) and GSE21374 (n =282), were obtained, which contained the whole transcriptome sequencing information of allograft biopsies within one year. Differential expressed genes (DEGs) were selected in common from GSE25902 and GSE57387 arrays. Then, the univariate and multivariate Cox regression model identified the independent graft-prognostic genes and a graft-prognostic index (PI). The diagnostic efficacy of this PI was validated by GSE21374 array. Finally, gene set enrichment analysis (GSEA) and Cibersort analysis were performed to screen key enriched pathways and biological process.

Results: A total of 41 DEGs were identified and four DEGs, including ABI3BP, PALMD, TW4SF18, and WFDC, were selected as prognostic genes for allograft survival. A PI containing these four prognostic genes was established and good test power was validated in GSE21374 array. Moreover, the PI was found to be related with the occurrence of acute rejection, enriched in graft-associated and immune-associated biological processes or pathways, as well as in Wnt/beta-catenin pathway, which was confirmed by immunofluorescence in tissues from kidney transplanted recipients with CAI. In addition, The Cibersort analysis suggested macrophage polarization as a crucial mediator during CAI.

Conclusions: We analyzed transcriptome data from three GSE arrays and established a graft-prognostic index, which showed a good test power to predict the allograft survival following renal transplant. This PI was also suggested to be correlated with a variety of immune-related biological processes and signaling, especially the Wnt/beta-catenin pathway, and macrophage polarization may contribute to the pathogenesis of CAI.

Abstract# 681

Nomogram of Quantity of Peripheral Cxcr5$^+$Cd8$^+$ T Cells, Aims to Predict Risk of De Novo Dsa in First-time Kidney Transplant Recipients

J. Zimmerer[1], M. Abdel-Rasoul[2], G. Bumgardner[1], [1]*OSU, Columbus, OH,* [2]*Center for Biostatistics, OSU, Columbus, OH*

Purpose: We recently reported that peripheral CXCR5$^+$CD8$^+$ T cells are inversely associated with the risk of developing *de novo* DSA (*dn*DSA) in the first year after kidney transplantation (Tx). Using data from our single center study we aimed to develop a pilot nomogram as a tool to determine risk of developing *dn*DSA.

Methods: We prospectively monitored 95 first-time KTx recipients (53.3±11.8 years old, 41% female, 21% African American, 32.6% deceased donor recipients) for development of *dn*DSA for 1 year posttransplant using single antigen beads (MFI >2000). All recipients received the same immunosuppression (IS) regimen [ATG induction therapy, 5-day steroid taper, and dual maintenance IS with a calcineurin inhibitor (CNi) and mTORi]. In addition to the detection of *dn*DSA, we prospectively and serially analyzed recipients for IS levels, HLA and eplet mismatch, and peripheral blood mononuclear cell (PBMC) subsets.

Results: Twenty-three recipients (24.2%) developed *dn*DSA within 1-year postTx. There was no difference in IS levels throughout the first-year postTx between DSA-positive and DSA-negative recipients. PreTx quantities of peripheral blood CXCR5$^+$CD8$^+$ T cells were inversely associated with the incidence of *dn*DSA (DSA+= 15,200±11,600 CXCR5$^+$CD8$^+$ T cells per million PBMCs vs. DSA-=26,300±17,600; p=0.04). PreTx quantity of CD4$^+$ T cell subsets (Th1, Th2, Treg) were not associated with the incidence of *de novo* DSA. Although we did not find a significant difference in HLA mismatch between the DSA+ vs. DSA- KTx recipients (6.8±2.1 vs. 6.0±2.1; p>0.05), when we compared the more precise Ab-verified HLA eplet mismatches we found that the number of HLA class I eplet mismatches significantly associated with development of *dn*DSA at one year postTx (DSA+= 12.4±4.4 mismatches vs. DSA-= 8.6±4.1; p=0.006). In **Figure 1**, we use theoretical patient profiles for quantity of CXCR5$^+$CD8$^+$ T cells and number of HLA I eplet mismatches to demonstrate how the independent risk factors (IRF) used to develop this nomogram would influence the estimated percent risk for postTx DSA. Theoretical preTx quantity of CXCR5$^+$CD8$^+$ T cells and number of HLA I eplet mismatches were used to assign IRF points and total (combined risk factor) points that predict percent risk of developing *dn*DSA after KTx. This exercise demonstrates how patients with the same HLA related risk (HLA I eplet mismatch) could have disparate risk of *dn*DSA based on their preTx quantity of CXCR5$^+$CD8$^+$ T cells.

Conclusions: Future prospective clinical studies are planned to assess and validate the accuracy of the nomogram.

	Quantity of CXCR5⁺CD8⁺ T cells per million PBMC		HLA Class I eplet mismatch		Total points	Percent Risk of DSA production
Pt 1	80,000 (10 points)	"high" CD8, low risk	5 (23 points)	"low" HLA, low risk	33	< 5%
Pt 2	10,000 (90 points)	"low" CD8, high risk	5 (23 points)	"low" HLA, low risk	113	15%
Pt 3	80,000 (10 points)	"high" CD8, low risk	18 (82 points)	"high" HLA, high risk	92	5%
Pt 4	10,000 (90 points)	"low" CD8, high risk	18 (82 points)	"high" HLA, high risk	172	80%

Fig. 2. "Pilot" Nomogram to Quantify Risk of de novo DSA Production after Kidney Transplant (KTx). In our single center study of 95 KTx recipients, results were used to create a pilot nomogram using the quantity of CXCR5⁺CD8⁺ T cells (pretransplant; per million PBMCs) and antibody-verified HLA class I (A,B,C) eplet mismatches (HLAMatchmaker). Width of red lines indicate the confidence intervals (CI) for individual risks factors at the assigned points. For a given patient, individual risk factor (IRF) points are assigned for quantity of CXCR5⁺CD8⁺ T cells and number of HLA class I eplet mismatches (see hypothetical results for patients (Pt 1 to Pt 4 and corresponding blue, yellow, green, purple arrows). The sum of IRF points (Total Points) is associated with a relative risk of DSA production after KTx. The nomograms AUC score is 0.80 (CI of 0.64 to 0.96).

Abstract# LB 29

Torque Teno Virus Load Predicts Allograft Rejection but Not Viral Infection After Kidney Transplantation; A Cohort Joint Modelling Study

A. L. van Rijn[1], H. F. Wunderink[2], I. A. Sidorov[1], C. S. de Brouwer[1], A. C. Kroes[1], H. Putter[3], A. P. de Vries[4], J. I. Rotmans[4], M. C. Feltkamp[1], *[1]Medical Microbiology, Leiden University Medical Center, Leiden, Netherlands, [2]Medical Microbiology, University Medical Center Utrecht, Utrecht, Netherlands, [3]Medical Statistics, Leiden University Medical Center, Leiden, Netherlands, [4]Internal Medicine, Leiden University Medical Center, Leiden, Netherlands*

Purpose: The main challenge of immunosuppressive therapy after solid organ transplantation is to find the optimal dose regimen, and prevent allograft rejection as well as opportunistic infection. Torque teno virus (TTV; ubiquitous and non-pathogenic) has been proposed as a marker of functional immunity in immunocompromised patients. We investigate whether TTV loads predict the risk of common viral infection and allograft rejection in kidney transplantation (KTx) recipients.
Methods: In a retrospective cohort of 389 KTx recipients, individual TTV loads in were measured by qPCR in consecutive plasma samples during one year follow-up. The endpoints were allograft rejection, BK polyomavirus (BKPyV) viremia and cytomegalovirus (CMV) viremia. Repeated measures and survival data were analysed in a joint model.
Results: During follow-up TTV was detected in 100% of KTx recipients. The median viral load increased to 10^7 genome copies/ml 3 months after KTx. Rejection, BKPyV viremia and CMV viremia occurred in 23%, 27% and 17% of the patients, respectively. With every 10-fold TTV load-increase, the risk of rejection decreased considerably (HR: 0.74, CI 95%: 0.71-0.76), while the risk of BKPyV and CMV viremia remained the same (HR: 1.03, CI 95%: 1.03-1.04 and HR: 1.01, CI 95%: 1.01-1.01).
Conclusions: In conclusion, TTV load kinetics predict allograft rejection in KTx recipients, but not the BKPyV and CMV infection. The potential use of TTV load levels as a guide for optimal immunosuppressive drug dosage to prevent allograft rejection deserves further validation.

Abstract# LB 30

Cellular and Genetic Signatures of Operational Tolerance in Kidney Transplant Recipients Through Single Cell R N A Sequencing Analysis

H. BAE[1], H. Lee[2], J. Ryu[3], B. Chung[2], E. Oh[3], *[1]Department of Biomedical Science, Graduate School, College of medicine, The Catholic university of Korea, Seoul, Seoul, Korea, Republic of, [2]Department of Internal Medicine, Division of Nephrology, College of Medicine, Seoul St. Mary's hospital, the Catholic University of Korea, Seoul, Korea, Republic of, [3]Department of Laboratory Medicine, College of medicine, The Catholic university of Korea, Seoul, Seoul, Korea, Republic of*

Purpose: Patients with operational tolerance do not use immunosuppressants after renal transplantation, but they show stable post-transplant results. We analyzed differently expressed mRNAs and proteins by targeting immune genes to single cells in patients with rejection, stable, and tolerance after kidney transplantation to see the relation of post-KT stability and genetic signatures.
Methods: This experiment was conducted with peripheral blood mononuclear cells (PBMC) of 7 post-KT rejection patients, 4 post-KT stable patients, and 5 post-KT tolerance patients. Through targeted multi-omic analysis, 16595 (rejection group), 7189 (stable group), and 16725 (tolerance group) single-cell transcriptomes were analyzed. We added 20 different types of ab-seq to the targeted panel to complement for the relationship between proteins and transcripts.
Results: We found 18 subclusters in the PBMC samples of three groups and confirmed the expression of mRNA and protein targeted by the immune panel among the subpopulations. We found the difference in the expression level of each group of NK cells, CD4 T cells, CD8 T cells, B cells, Treg cells, B memory cells and B naive cell populations. And significantly different mRNA expression was confirmed in the same cell population of different groups. In tolerance patients, CD56(Ab) was highly expressed in B cells, CD4 T cells, and Treg cells, and CD196(Ab) was highly expressed in B memory cells and B naive cells. CD8(Ab) was highly expressed in NK cells. Rejection group showed increased expression of HLA-DRA and CD74 in CD4 T cells, S100A10 in B memory cells, and CD38(Ab) in CD8 T cells. In stable patients, the expression of CD127(Ab) on CD8 T cells, PASK in CD4 T cells, and CD24, CCR7and CCL22 in B memory cells for each group.
Conclusions: Analysis of transcript expression at the single cell level characterizes the phenotype of cells and defines their functional properties. We found that the operational tolerance group expressed markers that differed from the rejection and stable group.

Abstract# LB 31

Estimated GFR by Serum Myo-inositol, Valine, Creatinine, and Cystatin-c Outperforms Current CKD-epi Equations in Renal Transplant Recipients

J. W. Meeusen[1], F. Stammler[2], J. Lieske[3], M. Grassi[2], M. Shah[4], E. Schiffer[2], *[1]Cardiovascular Laboratory Medicine, Mayo Clinic, Rochester, MA, [2]Research and Development, Numares, Boston, MA, [3]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN, [4]Clinical Research, Numares, Boston, MA*

Purpose: Current estimated GFR (eGFR) equations using creatinine and/or cystatin C do no perform well in kidney transplant (KTx) recipients. Therefore, some large transplant programs instead measure GFR as part of their routine pre and post-transplant protocols. However, these methods are expensive and not readily

available in many areas. Recently, we developed a novel GFR equation, which utilizes serum myo-inositol, valine and creatinine quantified by nuclear magnetic resonance spectroscopy (NMR) in combination with Cystatin-C measured by immunoturbidometric assay, age and sex (GFR_{NMR}). In the current study we evaluated performance of this equation in a cohort of KTx recipients.

Methods: GFR was measured (mGFR) by renal Iothalamate clearance in 109 post KTx patients that scheduled visits as part of routine clinical care (573 days; range 2-5217 days). mGFR was compared to $eGFR_{NMR}$, as well as the CKD EPI equations using creatinine ($eGFR_{Cr}$), Cystatin C ($eGFR_{CyC}$), or both ($eGFR_{Cr\ CyC}$).

Results: $CKD\text{-}EPI_{cys}$ was the least accurate with a P_{30} value of 0.73 and a MAE of 10.7 ml/min/1.73m². $CKD\text{-}EPI_{cr}$, was better with a P_{30} of 0.81 and a MAE of 9.53 ml/min/1.73m². The $CKD\text{-}EPI_{cr\text{-}cys}$, which has been established to lessen the effects of age, sex and race to improve GFR estimation, had a P_{30} value of 0.87 and a MAE of 9.41 ml/min/1.73m². Subgroup analysis of individuals with GFR < 60ml/min/1.73m² showed that this formula significantly underestimates renal reserve in renal transplant recipients. In contrast, GFR_{NMR} across the entire range of GFR showed good accuracy to measured GFR with a P_{30} of 0.92 and a MAE of 7.45 ml/min/1.73m². Further subgroup analysis of individuals with a GFR < 60 ml/min/1.73m² showed minimal bias with mGFR.

Conclusions: Our study demonstrates the potential utility of a novel $eGFR_{NMR}$ method for assessing kidney function in post KTx patients. This equation has improved performance compared to the established and widely utilize CKDEPI equations. Thus, $eGFR_{NMR}$ has great potential as a cost effective and non-invasive alternative to mGFR that could be widely available as a referral laboratory test. Further studies are necessary to validate this novel equation in additional post Tx and other CKD and non CKD cohort.

Comparison of GFR Equation Performance to mGFR				
	mean GFR (SD)	**MAE (95%CI)**	**P30 (95%CI)**	**RMSE (95%CI)**
mGFR	55.83 (20.28)	Ref	Ref	Ref
$eGFR_{NMR}$	55.74 (19.12)	7.45 [6.3-8.47]	91.74 [87.16-97.25]	9.42 [8.31 -10.58]
$eGFR_{cr}$	51.75 (19.83)	9.53 [8.11 -10.93]	80.73 (74.31-88.07)	12.23 (10.65-13.93)
$eGFR_{CyC}$	48.14 (20.98)	10.74 (9.26-12.26)	72.48 (64.22-80.73)	13.61 (12.01-15.39)
$eGFR_{CRCyC}$	48.99 (19.87)	9.41 (8.09-10.75)	87.16 (80.73-93.55)	11.78 (10.39-13.22)

Abstract# LB 32

AlloMap Kidney Gene Expression Profiling Discriminates Rejection from Immuno-Quiescence in Renal Transplant Recipients

E. Akalin[1], A. Djamali[2], H. Xu[3], X. Jin[3], R. N. Woodward[3], S. Dholakia[3], J. S. Bromberg[4], *[1]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [2]University of Wisconsin, Madison, WI, [3]CareDx, Brisbane, CA, [4]University of Maryland School of Medicine, Baltimore, MD*

Purpose: Assessment of immune activation is important when considering pathologies such as allograft rejection as well as potential interventions that may extend allograft survival. Optimizing interventions by assessing impact through quantifiable measures such as biomarker changes can drive the paradigm shift from reactive to proactive care. Here we describe validation of a blood gene expression profile (GEP) to inform on both T cell-mediated (TCMR) and antibody-mediated (ABMR) rejection.

Methods: A classifier using 5 informative genes was developed to discriminate quiescence from rejection using 21 samples from healthy, stable patients (HS, no clinical signs or symptoms) and 18 active rejection samples from the DART study (NCT02424227) patients. The "AlloMap Kidney" GEP signature was validated in an independent set of samples from the DART study using the targeted RNA sequencing. The validation samples comprised 45 non-rejection (NR, negative for-cause biopsy); 28 quiescent (Q, negative protocol biopsy); 27 HS; 7 T cell-mediated rejection (TCMR), 10 antibody-mediated rejection (ABMR), and 1 mixed rejection. In addition to AlloMap Kidney GEP, AlloSure dd-cfDNA was also performed.

Results: AlloMap Kidney scores (range 0-20) were significantly different between the control groups (Q, NR, HS) and rejection groups (ABMR, TCMR, Combined Rejections) (Figure). Median (IQR) results: Q=8.77 (7.52-11.11), NR=10.12 (8.15-12.17), HS=9.45 (8.26-11.55), ABMR = 11.50 (10.84-13.15), TCMR=15.14 (12.93-16.69). The scores of the combined rejection group were statistically significant from that of both the NR (p=0.003) and Q groups (p=0.001); and the ROC analysis demonstrated an AUC of 0.77 (95% CI 0.70-0.84) and 0.81 (95% CI 0.74-0.88), respectively. Sub-study assessment of the TCMR results showed that higher grade rejection samples have generally higher AlloMap scores.

Conclusions: Validation of AlloMap Kidney GEP provides a strong indication of the ability to distinguish graft rejection from immune quiescence. Quantification across a range of scores allows dynamic assessment compared to binary outputs and supports the applicability observed in heart transplantation. AlloMap Kidney has a strong association with TCMR and also identifies AMR. The performance suggests a complementary use with AlloSure for dd-cfDNA, combining immunological assessment with informative data on allograft injury.

Abstract# LB 33

Precision Medicine in Renal Transplantation: T-cell Repertoire Sequencing to Define Donor-specific Clones for Post-transplant Monitoring

K. R. Sherwood[1], P. Wong[1], F. Fenninger[1], V. Wu[1], J. Beckrud[2], D. P. Cina[3], L. Allan[2], J. Lan[2], P. A. Keown[2], *[1]University of British Columbia, Vancouver, BC, Canada, [2]Vancouver General Hospital, Vancouver, BC, Canada, [3]Urologic Sciences, Vancouver General Hospital, Vancouver, BC, Canada*

Purpose: Measuring donor-specific clonal responses offers a precise, sensitive and specific biomarker of immune recognition and activation. Combining deep immunophenotyping (DI) and T-cell receptor (TCR) sequencing, we have developed an in vitro platform to define the cellular proliferation response and the T cell clonal repertoire during stimulation by donor antigen as a prelude for clinical post-Tx monitoring.

Methods: A matrix design with repeated measures over time was employed using one-to-many and many-to-one stimulator/responder combinations in mixed lymphocyte culture (MLC). Donor and responder PBMC (stained respectively with Cell Trace CFSE and Violet) were cultured for 7 days in MLC. DI was performed daily with α-CD3, α-CD4, α-CD8, α-CD197, α-CD45RA, α-HLA-DR, α-CD127,

α-CD25 and α-CD152. For TCR sequencing genomic DNA was isolated, library preparation performed using ImmunoSeq, sequenced on an Illumina MiSeq System and analyzed on the ImmunoSEQ 3.0 portal.

Results: Expansion of T cell subsets are clearly observed from day 4 onwards (Fig.1a). In the proliferating T cells, a significant number were CD4 and CD8 positive (double+) and by day 7 most had become effector memory T cells (not shown). Sequence results of post-challenge samples reveals both an increase in relative diversity and maximum productive frequencies of CDR3 rearrangements. Expansion of few specific clones at high frequency post-challenge were frequently observed and were easily identified from a background of low frequency clones (Fig. 1b). Proliferation may also occur through a mechanism of polyclonal expansion (not shown). Repeated measures over time for control samples showed considerably more overlap than other pairwise comparisons. Clones that emerge in MLC response were also consistently detected at multiple time-points (not shown).

Conclusions: This robust in vitro assay provides deep insight into the proliferating T-cell populations and TCR gene utilization following allogeneic stimulation. Baseline and stimulated TCR gene utilization varies within individual over repeated measures indicating heterogeneous clonal proliferation, but high frequency clones are identified which provide the focus for monitoring of the allogeneic response in the transplant recipient.

Basic

Tolerance: Clinical Studies

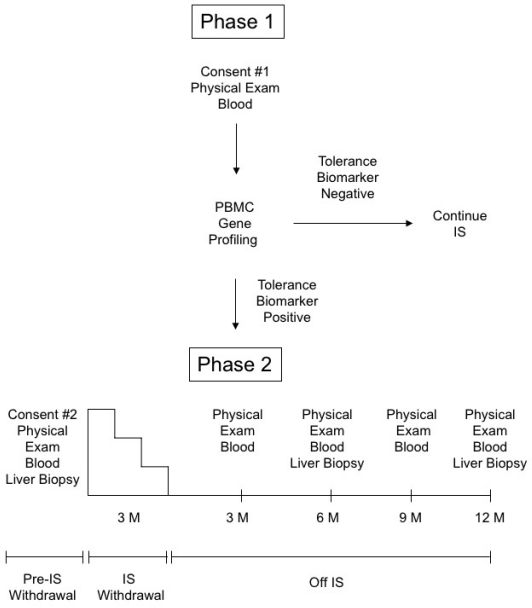
Abstract# 682

Results of Litmus (nct 02541916): The Liver Immune Tolerance Bio Marker Utilization Study

A. Chruscinski[1], V. Rojas-Luengas[1], A. Issacher[1], L. Lilly[1], E. Renner[1], M. Epstein[1], O. Adeyi[1], S. Fischer[1], Z. Galvin[1], S. Moshkelgosha[1], E. Jaeckel[2], S. Juvet[1], N. Selzner[1], G. Levy[1], *[1]Multi-Organ Transplantation, University Health Network, Toronto, ON, Canada, [2]Hannover Medical School, Hannover, Germany*

Purpose: Although it is known that some liver transplant recipients are operationally tolerant and can be weaned off immunosuppression (IS), there is not currently a validated biomarker platform to identify these patients. Here we investigated if a gene biomarker profile predictive of tolerance in preclinical studies could identify operationally tolerant recipients.

Methods: We developed GeXP RT-PCR assay to monitor expression of eight target genes (*FGL2, FOXP3, TGF*-β1, *LAG3*, *TIGIT*, *IL-10*, *IFN-γ*, and *GZMB*) previously identified to corelate with tolerance in pre-clinical models. Gene expression was measured in peripheral blood mononuclear cells (PBMC) from adult liver transplant recipients who were a minimum of six months post-transplant and had no biochemical evidence of rejection. Patients who positive for a putative tolerance biomarker (*FGL2*/*IFN-γ* ≥1) underwent a liver biopsy. If the liver biopsy was normal, patients underwent IS withdrawal over a three-month period. The primary aim of the study was the development of operational tolerance. Secondary endpoints were mortality, graft loss and changes in adverse effects associated with cessation of immunosuppression.



Results: Sixty-nine patients enrolled in the study, and 28 (41%) were positive for the tolerance biomarker. Of these 28 patients, 23 had evaluable outcomes including 8 patients who were successfully withdrawn from IS, 6 patients who developed rejection during IS withdrawal, and 9 patients who had abnormal baseline liver biopsies. Six of eight of the patients successfully withdrawn from IS are now designated as operationally tolerant as they are off IS greater than one year. GeXP analysis of baseline liver biopsies revealed that 8/8 (100%) of patients in the successful withdrawal group had a liver gene ratio of *FOXP3*/*IFN-γ* ≥1, whereas only 1/6 (17%) patient in the rejector group had this gene ratio. Additional immunologic studies demonstrated increased regulatory T cells (Treg) in the peripheral blood and in the liver allograft of operationally tolerant patients post-IS withdrawal.

Conclusions: These data suggest that a combination of gene expression monitoring in PBMC and in the liver allograft may identify operationally tolerant liver transplant recipients, allowing for successful withdrawal of immunosuppression.

Abstract# 683

Expansion of Cd45ra-foxp3hi Activated Regulatory T Cells Predict Immune Tolerance in Patients with Combined Kidney and Bone Marrow Transplantation

Y. Kwon[1], K. Lee[2], J. Park[2], *[1]Transplantation Research Center, Samsung Medical Center, Seoul, Korea, Republic of, [2]Department of Surgery, Samsung Medical Center, Seoul, Korea, Republic of*

Purpose: Simultaneous transplantation of a solid organ and bone marrow from an identical donor is a possible means of achieving transplant tolerance. Here, we attempted to identify biomarkers that indicate transplant tolerance for discontinuation of immunosuppressants in combined kidney and bone marrow transplantation (CKBMT).

Methods: We compared various immunological parameters that evaluate the transplant tolerance status between conventional kidney transplanted (KT) recipients (n = 20) and CKBMT recipients (n = 6) by using flow cytometry. To measure the anti-donor responses, mixed lymphocyte reaction (MLR) assays were performed with responder peripheral blood mononuclear cells (PBMCs) of CKBMT recipients and stimulator PBMCs of autologous, donor, and third party.

Results: Among six CKBMT recipients, three successfully discontinued immunosuppressants (tolerant group) and three could not (non-tolerant group). The $CD45RA^{-}FoxP3^{hi}$ activated regulatory T (Treg) cell subpopulation was expanded in CKBMT recipients compared to conventional kidney transplant patients, and this was more

obvious in the tolerant group than the non-tolerant group. The ratio of CD45RA$^-$FoxP3^{hi} activated Treg cells to CD45RA$^-$FoxP3^{lo} non-suppressive cells showed good discrimination between the tolerant and non-tolerant groups.
Conclusions: Thus, our findings propose a biomarker that can distinguish CKBMT patients who achieve transplant tolerance and are eligible for discontinuation of immunosuppressants and may provide insight into tolerance mechanisms in CKBMT.

Abstract# 684

Inducing Transient Mixed Chimerism without Chimeric Transition Syndrome for Tolerance Induction After Kidney Transplantation

K. Lee, J. Park, *Samsung Medical Center, Seoul, Korea, Republic of*
Purpose: Immunological or operational tolerance, defined as the absence of a destructive immune response to a transplanted tissue without ongoing immunosuppression, is one strategy that may improve the long-term results of organ transplantation; avoiding the morbidity associated with chronic immunosuppression and graft dysfunction. Inducing transient mixed chimerism is one of the way to operational tolerance after kidney transplantation (KT). Kawai and colleagues have reported on their experience about the inducing transient mixed chimerism and operational tolerance after KT. However, they reported that almost all patients experienced an early engraftment syndrome-like condition termed chimeric transition syndrome (CTS). This CTS is considered as a major hurdle to be overcame in this group.
Methods: At first, we developed our protocol for combined kidney and bone marrow transplantation (CKBMT) based on the protocol of MGH. The only difference from the MGH regimen was the substitution of rATG for anti-CD2 mAb, which was not available in Korea. After experiencing side effects of preconditioning regimen including CTS, cyclophosphamide toxicity, and uncontrolled BK virus infection, we have revised protocol by reducing dose of cyclophosphamide (22.5 mg/kg x 2 doses) and adding fludarabine (10 mg/kg x 4 doses).
Results: By far, we applied our latest revised protocol for 9 patients. Among them four patients successfully discontinued immunosuppression (IS) and five patients are on the process of IS weaning. All of them showed sufficient bone marrow suppression after preconditioning and transient mixed chimerism (2~24wk) after CKBMT. None of these patients showed unexplainable serum creatinine elevation in early post-operative period. (Figure. 1) Protocol biopsy performed at 2 week after CKBMT showed no abnormal findings in all patients. None of patients suffered from uncontrolled BK virus infection or side effect cyclophosphamide which were observed in patients treated with previous protocols.
Conclusions: With the revised protocol, transient mixed chimerism can be induced without CTS. Further follow up is necessary to ensure the efficacy of this protocol in the aspect of inducing operational tolerance.

Abstract# 685

Long-Term Follow-Up of a Phase 2 Clinical Trial to Induce Tolerance in Living Donor Renal Transplant Recipients

J. Leventhal[1], J. Galvin[2], J. Mathew[1], L. Gallon[1], D. Belshe[1], M. Gibson[1], K. Ravindra[3], M. Horwitz[3], S. Ildstad[4], *[1]Northwestern University, Comprehensive Transplant Center, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Duke Medical Center, Durham, NC, [4]University of Louisville, Llouisville, KY*
Purpose: 37 subjects were transplanted in a phase 2 protocol based upon tolerogenic CD8+/TCR-facilitating cells (FCR001) to induce tolerance in recipients of living donor renal allografts (KTx).
Methods: Recipients were conditioned with fludarabine (30mg/m2/dose, days -5,-4,-3), cyclophosphamide (50mg/kg/dose, day-3 and+3), 200 cGy TBI (day-1) followed by KTx (day0). A G-CSF mobilized product was apheresed from the donor, processed to remove graft-versus-host disease (GVHD)-producing cells yet retain CD34 + cells and FC, and cryopreserved until administration day+1 post-KTx. Follow up is 48 - 136 months. Pts ranged in age from 18-64 yrs and were 6/6 HLA matched related to 0/6 matched unrelated. MMF and tacrolimus immunosuppression (IS) was weaned and discontinued at 1 yr if post-Tx chimerism, normal renal fcn and normal KTx biopsy were noted.
Results: Durable chimerism allowing for full IS withdrawal developed in 26 pts (time off IS 37- 124 months); the majority (23/26) showed full (>95%) donor whole blood/T cell chimerism. Transient chimerism was seen in 8 pts. All stable chimeric subjects retained chimerism after removal of IS and remain rejection-free. Long term chimeric subjects off IS have no clinical evidence of immune defect: they show robust T, B, and NK cell reconstitution, can be safely vaccinated and develop protective immunity. Transiently chimeric pts resumed endogenous hematopoiesis and were maintained on low-dose IS. There were two cases of GVHD. 1 subject exhibited grade 1-2 acute GI GVHD that responded to corticosteroids, followed by mild chronic GVHD. The second pt presented late and died of treatment resistant GI GVHD with CMV 11 months post-Tx. There have been three graft losses, related to infections in subjects on IS. Two additional deaths have occurred in pts off IS: one in a heavy (>100 pack year) smoker from advanced stage lung cancer 4.5 years after KTx, the second in a pt 3.5 years after KTx who developed pneumococcal sepsis after noncompliance with recommended vaccinations. Overall survival is 91.8% and death censored graft survival 94.1%. Tolerant FCR001 subjects have significantly better renal function than comparable KTx on SOC IS. Hypertension and hyperlipidemia is more common in SOC than tolerant FCR001 pts.
Conclusions: In summary, high levels of durable chimerism and tolerance with a low (5.5%) incidence of GVHD has been achieved in mismatched recipients of KTx. There are significant long term medical benefits to establishing tolerance in KTx recipients using the FCR001 approach.

Ethics

Psychosocial and Treatment Adherence

Abstract# 706

Posttraumatic Stress and Medication Adherence in Pediatric Transplant Recipients

S. Duncan-Park[1], L. Danziger-Isakov[2], B. Armstrong[3], N. Williams[4], J. Odim[4], E. Shemesh[5], S. Sweet[6], R. Annunziato[1], *[1]Icahn School of Medicine at Mount Sinai and Fordham University, New York, NY, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Rho Inc., Durham, NC, [4]NIAID, Bethesda, MD, [5]Icahn School of Medicine at Mount Sinai, New York, NY, [6]Washington University in St. Louis, St. Louis, MO*
Purpose: We investigated the relationship between posttraumatic stress symptoms (PTSS), medication adherence, and quality of life (QoL) in adolescent transplant recipients.
Methods: This protocol of the Clinical Trials in Organ Transplantation in Children Consortium (CTOTC-11, NCT02892266) included solid organ transplant recipients 12 to 17 years old who were prescribed tacrolimus and had received a transplant ≥ 18 months prior to enrollment. Patients and caregivers rated PTSS using the UCLA PTSD Reaction Index (threshold ≥ 35) and Impact of Event Scale (threshold ≥ 18),

respectively, at enrollment. Outpatient tacrolimus trough level data were collected for one year (6 months pre- and post-enrollment) to calculate the Medication Level Variability Index (MLVI), a measure of medication adherence.

Results: MLVI and PTSS were examined in the full sample (n=119, 118 with sufficient levels to calculate MLVI) and a pre-defined subgroup of liver recipients (n=48), as MLVI threshold has been validated in liver recipients only. The sample included liver (39.5%), kidney (28.6%), heart (16.8%), lung (14.3%), and intestine/liver (0.8%) recipients. Nonadherence (MLVI ≥ 2) was identified in 35.6% of patients and 27.1% of liver recipients. Most patients (80.7%) reported exposure to at least one potentially traumatic event (PTE), including illness/medical trauma (53.8%), bereavement (46.2%), bullying (24.4%), and serious accidental injury (15.1%). Above-threshold PTSS was endorsed by 9.2% of the full sample, 12.5% of liver recipients, and 43.7% of caregivers. PTSS and MLVI were significantly correlated only in the liver subgroup (r=0.31, p=.03). In multivariable regression analyses, patient and caregiver posttraumatic stress avoidance symptoms predicted lower QoL (F=12.94, p<.001), but not MLVI (F=0.70, p=0.50); however, only total patient PTSS, rather than avoidance symptoms specifically, were significant in subsequent hierarchical multivariable linear regression analyses (B=-0.78, *B*=-0.78, p<.001).

Conclusions: PTEs are common in adolescent transplant recipients; a minority may meet criteria for PTSD. Screening for PTSS to identify nonadherence risk is not warranted; however, addressing PTSS may help improve quality of life. Caregivers are at greater risk for PTSD than patients, and therefore may require their own supports during the post-transplant period.

The writing team acknowledges the important contributions of investigators from participating CTOTC-11 sites.

Abstract# 707

A Psychosocial Clinician Rating Scale is Used Differently Across Solid Organ Teams within a Single Transplant Center

S. Entenman[1], T. Chaffee[2], M. Pienta[3], B. Young[3], E. Clifton[1], J. Mellinger[4], L. McElroy[5], G. Winder[1], *[1]Psychiatry, University of Michigan, Ann Arbor, MI, [2]Psychiatry, University of Missouri-Kansas City, Kansas City, MO, [3]Surgery, University of Michigan, Ann Arbor, MI, [4]Internal Medicine, University of Michigan, Ann Arbor, MI, [5]Surgery, Duke University, Durham, NC*

Purpose: Transplant psychosocial clinician rating scales like the Stanford Integrated Psychosocial Assessment for Transplant (SIPAT) are widely used tools to standardize subjective patient data, stratify risk, supplement clinician decision-making, and facilitate research. Psychosocial clinicians within a single center often evaluate candidates and assign SIPAT scores across diverse transplant patient populations. The goal of this study was to describe how different solid organ teams use and apply the SIPAT despite the uniformity of the instrument's criteria and interpretation. In 2015, Michigan Medicine deployed the SIPAT for use on all its solid organ transplant teams.

Methods: Adult solid organ transplant candidates between 2015-18 were queried for SIPAT score at the time of transplant evaluation. For patients who were evaluated multiple times or for multiple organs, the first evaluation was used. Rates of SIPAT use were compared among the organ teams. SIPAT scores range in categories from excellent (0-6) to poor (> 70). Mean SIPAT scores were compared between listed, non-listed, transplanted and non-transplanted candidates. Chi-square tests were used for categorical data; ANOVA was used for continuous data.

Results: A total of 5108 patients were evaluated during the study period. The majority of patients were male (60%), Caucasian (73.7%), and married (46.0%). Age at first evaluation varied significantly across organs. 2630 of 5106 (51.5%) patients received a SIPAT score, with scores ranging from 0 to 87. Kidney and liver were the most avid SIPAT users followed by kidney-pancreas and pancreas, lung, and heart (see Table 1). Mean scores of listed, non-listed, transplanted, and non-transplanted patients, were all statistically different across the organ teams. Intuitively, SIPAT scores trended higher for non-listed and non-transplanted patients.

Conclusions: These cross-organ differences in SIPAT frequency and mean scores are relevant to all psychosocial clinicians, particularly those evaluating candidates for separate organs and interacting with different transplant teams.

Table 1.

	Heart	Kidney	Kidney-Pancreas & Pancreas	Liver	Lung	
Number of patients evaluated	308	2661	196	1486	486	
Mean age at first organ evaluation (Standard Error)	48.95 (0.758)	53.95 (0.203)	41.42 (0.840)	54.87 (0.326)	54.30 (0.493)	$p < 0.001$, $F = 50.407$
Number patients who received SIPAT (%)	24 (7.79)	1934 (69.83)	77 (40.36)	771 (52.59)	154 (31.11)	$p < 0.001$, Pearson coeff. = 392.399
Mean SIPAT scores of listed patients (S.E.)	12.21 (2.921)	16.84 (0.282)	16.10 (0.912)	17.63 (0.660)	12.03 (0.981)	$p < 0.001$, $F = 7.727$

Abstract# 708

Development of a Question Prompt Sheet for Upper Extremity Vascularized Composite Allotransplantation

J. Gacki-Smith[1], B. Kuramitsu[1], A. Ferzola[2], K. Vanterpool[2], C. Kunkle[3], M. Hewitt[3], A. Schultheis[3], T. Riggleman[3], J. Taylor[3], C. Cooney[2], M. Levan[2], S. Tintle[3], G. Brandacher[2], E. Gordon[1], *[1]Northwestern University, Chicago, IL, [2]Johns Hopkins University, Baltimore, MD, [3]Walter Reed National Military Medical Center, Bethesda, MD*

Purpose: Upper extremity (UE) vascularized composite allotransplantation (VCA) is an innovative option for people with UE amputations. Individuals with limb loss commonly receive little information about treatment options and have limited communication with healthcare providers about their condition. Making informed treatment decisions can be difficult when information needs are unmet. Question prompt sheets (QPS) are structured lists of questions that can facilitate communication with providers by empowering patients to ask questions and acquire relevant information. No QPS is available for VCA. This study aimed to develop an UE VCA-specific QPS.

Methods: We conducted in-depth interviews among people with acquired UE amputations. Participants were asked about information needs about UE VCA to inform the initial QPS draft. A qualitative thematic approach was used to analyze open-ended responses. The multidisciplinary research team reviewed the QPS draft to improve organization, clarify question wording, and remove repetitive items.

Results: Thus far, 12 individuals completed an in-depth interview (75% participation rate). Most were male (71%), with a mean age of 49 years, and had a unilateral amputation (75%). Most participants (75%) reported being 'completely' or 'a lot' likely to use a QPS if they were considering UE VCA. The initial QPS draft included 77 items grouped into 16 topics. UE VCA topics and sample questions included: Eligibility (What makes a good candidate?); Matching (How does the donor matching process work?); Surgery (How is the hand or arm surgically connected to my body?); Function (How much hand function can I regain?); Risks (What happens if my body rejects the hand/arm? Is it removed?); Appearance (Will the new hand look noticeably different from my arm?); and Rehabilitation (What does rehabilitation involve?).

Conclusions: Preliminary findings suggest people with UE amputations desire information about VCA. The UE VCA-QPS draft will be refined via semi-structured interviews and team review for content validity, comprehensiveness, and readability. Future research should assess the impact of the UE VCA-QPS on communication and informed decision making about UE VCA.

Abstract# 709

"A New Lease on Life": Patient Perceptions After Early Liver Transplantation for Alcohol-Related Liver Disease

R. Greenberg, G. Punchhi, H. Sung, K. Gianaris, M. Krach, K. Herrick-Reynolds, P. Chen, M. Levan, J. Garonzik Wang, A. Cameron, *Johns Hopkins, Baltimore, MD*

Purpose: At some centers, alcohol-related liver disease (ARLD) patients, who are unlikely to survive six months without a liver transplant (LT), are selected to receive life-saving early liver transplantation (ELT) despite zero to minimal sobriety. ELT recipients' perceptions of their LT experiences have not been previously examined and can help inform ARLD transplant policies.

Methods: We conducted a preliminary thematic analysis of in-depth semi-structured interviews with 17 ELT recipients transplanted between December 2013 and July 2020, at a single center. Interviews focus on the ELT experience, alcohol use, and the six-month wait period guideline and will continue until thematic saturation is reached.

Results: A common participant perception was feeling thankful for a new liver. Participants expressed various motivations for taking care of their new livers and their health, characterizing the transplant as a "new lease on life." Participants described their changed attitudes towards alcohol post-LT and disclosed ongoing challenges, such as maintaining sobriety, "fighting" for self-identity, navigating stressors, and redefining their relationships. Regarding the six-month wait period, participants expressed a range of perspectives, from beliefs that a guideline may be helpful in some cases to criticisms that the guideline groups patients into "black

and white categor[ies]" and ignores their circumstances. Participants discussed the stigma of being perceived as an "alcoholic" and highlighted the struggle of trying to demonstrate sobriety while dealing with a "dead liver." Participants expressed a desire for specific supports for ARLD LT patients.
Conclusions: ELT recipients' perceptions illuminate the struggles and stigma associated with ARLD, as well as the direct impact of the six-month wait period on ARLD patients in need of an LT. These findings can help inform an ethical and evidence-based policy for transplanting ARLD patients.

Abstract# 710

Anonymous Live Liver Donor Perspectives on Anonymity in the Donation Process

S. S. Humar, N. Selzner, J. Jung, S. Krause, S. Abbey, *Multi-Organ Transplant Program, University Health Network, Toronto, ON, Canada*
Purpose: Anonymous living organ donation has recently become a more regular practice in select transplant programs, with donors coming forward voluntarily to give their organs to those in need. These donors may be directed or non-directed, and anonymity may be one-way or reciprocal. There is limited literature focusing on the psychosocial aspects of anonymity in living liver donors. Given the unique situation of these donors, we interviewed a sample of 26 anonymous live liver donors and explored their opinions surrounding the idea of anonymity and its implications in living liver donation.
Methods: Anonymous donors completed a semi-structured qualitative interview consisting of questions regarding their experiences as a donor. Donors were at least 18 years of age, fluent in English, and had donated at least 3 months prior to participating. Living donation surgeries had occurred between 2005 and 2016. Interviews were conducted over the telephone or in person by an experienced qualitative researcher during the time period September 2016 to April 2017. All interviews, ranging from 41 to 135 minutes in length, were audio-recorded, transcribed, and quality-checked. They were analyzed and categorized into common themes, specifically those pertaining to the donor's perceptions and experiences with anonymity.
Results: Of 40 eligible anonymous donors, 26 (65%) anonymous donors were interviewed. Out of the donors interviewed, 4/26 (15.4%) participated in a directed donation, meaning they had knowledge of the recipient's identity. In these cases, anonymity was one-way. The remainder were non-directed (two-way anonymity). The views of the directed donors did not appear to have any significant differences from the views of non-directed donors. Five main themes related to anonymity were identified as follows: (1) Ethical issues related to coercion and recipient indebtedness; the majority expressed that the recipient should not feel like they owe the donor anything in return; (2) Wanting internal satisfaction rather than seeking accolades—donation was a purely altruistic act; (3) Not wanting to be emotionally attached to the outcome in the recipient, thus avoiding the guilt and responsibility if the recipient had a complication; (4) Concerns about negative perceptions amongst their own friends and family, such as being referred to as "selfish" for risking their life; (5) Feelings of ambivalence towards meeting the recipient; although most donors were not opposed to meeting the recipient, they would not seek them out themselves.
Conclusions: These findings provide unique insight into living donor opinions on several aspects related to anonymity in the donation process. We identified five key drivers related to decisions surrounding anonymity. Knowledge of the donor's mindset and attitudes on the topic will help improve awareness and provide the best possible mental and physical care for the anonymous donor.

Abstract# 711

The Lived Experience of Older Adult Kidney Transplant Recipients: Reflections on Embodied Selfhood in Later Life

L. Kimberly, *New York University Langone Health, New York, NY*
Purpose: Although the number of older adults who might benefit from kidney transplantation continues to increase in the United states, little is known about older adults' lived experience of transplantation and the impact of transplant on their sense of embodied selfhood.
Methods: Employing a phenomenological research design, this study explored the lived experience of 10 deceased donor kidney transplant recipients aged 65 to 72 years old. Participants completed one to two in-depth phenomenological interviews lasting approximately one hour each, for a total of 15 interviews. The sample was drawn from a transplant center in an urban location in the United States. Interview transcripts and field notes were analyzed following the processes of phenomenological reduction, imaginative variation and synthesis.
Results: Analyses illuminated older adults' perceptions of the impact of kidney transplantation on their sense of physical, psychological and social selfhood. Participants reported experiencing physical and psychosocial challenges as they adjusted to their transplants, yet they also constructed powerful narratives of resilience and coping that were rooted in a deeply held sense of identity developed over the life course. This sense of continuity of the embodied self over time enabled most participants to better navigate the corporeal disruption and re-integration of transplantation. Participants expressed profound appreciation for their transplants and reported substantial improvement in quality of life as compared to their pre-transplant experience on dialysis. Most participants perceived their older age as playing a protective role in the recovery process.
Conclusions: These findings shed light on benefits of older age for kidney transplant recipients that may not be fully integrated into standard approaches to patient selection and assessment of transplant outcomes. As such, findings may help to address age-related bias in transplant policy and clinical practice, with the ultimate goal of improving wellbeing and quality of life for older adults.

Abstract# 712

Two Step Screening for Anxiety Symptoms in Solid Organ Transplant Recipients

H. Lan, F. Jamil, N. Al Kaabi, R. Aser, K. Gyatso, H. Habbal, S. Macanovic, S. Dano, M. Novak, I. Mucsi, *University Health Network, Toronto, ON, Canada*
Purpose: Patients with end-stage organ failure who receive organ transplants often experience anxiety symptoms. Currently, however, these symptoms frequently remain un-detected. Systematic screening for anxiety may help identify patients with moderate/severe symptoms, who may benefit from multidimensional assessment and support. The purpose of this study is to assess a 2-step approach, where an ultra-brief screening tool (Edmonton Symptom Assessment Survey-revised- Anxiety item (ESASr-A) or Generalized Anxiety Disorder-2 (GAD-2)) is followed by a more precise tool (Patient Reported Outcomes Measurement Information System Anxiety Computer Adaptive Test (PROMIS-A-CAT)), to screen for anxiety symptoms in solid organ transplant recipients.
Methods: In a multicenter cross-sectional study, we administered multiple symptom screening questionnaires to solid organ transplant recipients. Using data from patients who completed ESASr-A, GAD-7 and PROMIS-A-CAT, we compared screening performance and efficiency between the scenario in which patients completed PROMIS-A-CAT and hypothetical scenarios where only patients above the pre-screening cut-off would have completed PROMIS-A-CAT. Screening performance was evaluated by sensitivity and specificity. Efficiency was characterized by the average number of questions completed by subjects in the different scenarios.
Results: A total of 126 kidney transplant recipients, 71 liver transplant recipients, and 12 kidney pancreas recipients were included in this analysis. The mean (SD) age of the entire cohort was 54 (13) years and 61% of the subjects were male. For the 2-step method, using a cut-off of $\geq$1 and $\geq$2 for ESASr-A and GAD-2, respectively, produced the best combination of sensitivity and specificity (ESASr-A sensitivity 0.73, specificity 0.91; GAD-2 sensitivity 0.73, specificity 0.94). Most patients who completed more than 5 PROMIS-A-CAT items scored <3 on GAD-7. Compared to administering only PROMIS-A-CAT to all patients, the 2-step method reduced the average number of questions patients had to complete from 6 to 4 for both 2-step screening scenarios.
Conclusions: A 2-step anxiety screening method using either ESASr-A or GAD-2 followed by PROMIS-A-CAT has acceptable specificity and sensitivity, and can be most helpful to reduce questionnaire burden among patients with no symptoms. Screened in patients will need clinical assessment to establish diagnosis and decide on appropriate psychosocial support.

Abstract# 713

Impact of Rejection in Pediatric and Young Adult Kidney Transplant Recipients on the Use of Mental Health Resources

E. Ruzicka[1], E. Lyons[2], C. Naclerio[2], A. Sikora[2], K. McKinnon[2], E. Blanchette[2], M. Chandran[2], M. Bock[2], E. Christofferson[2], *[1]Children's Hospital Colorado, Aurora, CO, [2]University of Colorado, Aurora, CO*
Purpose: Allograft rejection often results in increased hospital and medical resource utilization. Pediatric kidney transplant recipients (KTR) are at risk for psychoso-

cial stressors, nonadherence to their medical regimen, and rejection episodes. We investigated allograft rejection in a pediatric and young adult KTR cohort and the related use of transplant psychologist resources.
Methods: This retrospective cohort study investigated pediatric KTR transplanted between January 2016 and November 2020. Data collected included baseline demographic and clinical information, immunosuppression regimen (induction and maintenance), rejection episodes (classification and severity), graft survival, and number of patient visits (in-person or virtually) with the transplant psychology team. Cost per psychologist visit was estimated based on average billing reimbursements at our institution.
Results: 111 pediatric/young adult KTR were included during the 5-year study period (M_{age}=12.32, 55% female, 71.2% White). 20 (18%) patients experienced 30 acute rejection episodes (median time to first rejection 369 days; IQR 245-669). Eight (7.2%) patients experienced 2 or more rejections. 106 (95.5%) patients were seen post-transplant (after hospital discharge) by transplant psychology. Patients who experienced acute rejection utilized significantly more mental health resources than those who did not reject (median 3 vs 8.5 transplant psychology sessions; IQR 2-10.2, p: 0.001), resulting in an increased cost of $2,321 and 220 minutes in direct patient care per patient, plus additional time required to coordinate the unique mental health needs of each patient.
Conclusions: Integrated behavioral health support, specifically targeting nonadherence and post-transplant stressors, is critical for successful transplant outcomes among pediatric KTR. Acute rejection among pediatric KTR may result in increased stress in a patient population already prone to psychosocial instability. Further, the cost of acute rejection extends beyond the economic and social impact of treating just its medical sequelae, to allocation of scarce mental health resources within transplant. Availability of transplant psychologists improves accessibility of psychological supports in this high-risk population, and programs should ensure their patients have access to this important service.

Abstract# LB 72

Death and Loss to Follow-up in Pediatric Liver Transplant Recipients Transferred to Adult Care: Who is at Risk?

J. P. Stevens[1], S. Gillespie[1], M. Katz[1], L. Hall[2], V. Kolachala[1], R. Ford[3], N. A. Gupta[1], *[1]Pediatrics, Emory University School of Medicine, Atlanta, GA, [2]Transplant Services, Children's Healthcare of Atlanta, Atlanta, GA, [3]Internal Medicine, Emory University School of Medicine, Atlanta, GA*
Purpose: With improvements in surgical technique and immunosuppressive regimens, many pediatric liver transplant recipients are surviving to adulthood. Successful transition to an adult provider is key to a patient's continued well-being. Mortality rates remain high in young adults with chronic medical conditions in the years following transfer. The purpose of our study is to analyze the relationship between demographic, psychosocial and clinical factors in children who received a liver transplant to assess risk of death or loss to follow-up in adulthood.
Methods: Retrospective, single center cohort study of patients who underwent pediatric liver transplantation between 1990-2015 at a large tertiary transplant center. Patient data was collected via electronic medical records, a national transplant database, telephone interview, and public death records.
Results: 120 patients were transferred to adult care, of which 101 met inclusion criteria. Sixty-four patients (63%) transferred to an affiliated adult facility, 29 (29%) were followed by another healthcare system, and 8 (8%) were lost to follow-up. In all, 23 patients died after transfer (25%). Several childhood factors were associated with higher rates of adult death: African American (AA) race (OR 6.59, p<0.001); psychiatric illness or substance use (OR 2.81, p=0.039); not obtaining a high school (HS) diploma (OR 9.59, p<0.001); medication non-adherence (OR 4.72, p=0.02); pediatric acute cellular rejection (OR 4.44, p=0.025); and co-morbidities of diabetes mellitus (DM) (OR 5.71, p=0.001) or renal insufficiency (OR 2.82, p=0.043). Not graduating HS was also associated with loss to follow-up (p<0.001). On multivariate analysis, AA race, substance use, and DM retained the highest association with adult death (OR 7.47, 9.16, and 3.76 respectively, all p<0.05). Not graduating HS was collinear with these factors, with an OR 9.65, p=0.011.
Conclusions: Complex, intertwined demographic, psychosocial and clinical factors are associated with increased rates of death in pediatric liver transplant recipients after transfer to adult care. Early recognition of high-risk patients, individualized transition processes, and further investigation into underlying causes of health disparities may improve long-term outcomes.

Abstract# 714

Solid Organ Transplant Recipients and Healthcare Burden in Covid19 Era

A. Basu, N. Sharma, R. Subramanian, L. Sridharan, S. Pastan, T. Pearson, *Emory Healthcare, Atlanta, GA*
Purpose: Pneumonia(PNA)- Acute inflammation of the lung parenchyma from an infection, is a frequent cause for hospitalization among Solid Organ Transplant Recipients (SOTRs), adversely effecting patient survival and healthcare costs. We assessed the healthcare impact associated with intensive care unit (ICU) hospitalization amongst SOTRs with COVID19 PNA or other serious PNAs.
Methods: We performed a single center retrospective analysis of SOTRs admitted to the ICU with any PNA during March 2019-October 2019 or with COVID19 PNA during March 2020-October 2020. Using t-tests and Chi Square tests we compared SOTRs with severe COVID19 PNA to those with other severe PNAs.
Results: 53 SOTRs with severe PNAs were included: 26 with COVID19 PNA and 27 with other PNAs (Bacterial 56%, Fungal 30%, Viral 14%). Both the groups were similar in demographics, time since transplant, length of stay and acute dialysis needs (Table 1). Mortality was higher in SOTRs with COVID19 PNA compared to other PNAs (46% Vs 22%; p 0.07). Hospitalization costs was greater in those with other PNAs compared to COVID19 PNAs ($553,000 VS $196,000; **p 0.006**) with fungal PNAs being associated with greatest costs (Figure1).
Conclusions: Critically ill SOTRs have substantially burdened the healthcare system with COVID19 associated mortality and healthcare expenses with other infections of equal severity. Every effort must be made to ensure timely assessment and diagnosis to minimize healthcare strains during this pandemic.

Abstract# 715

Utilization of Living Donor Liver Transplant for Patients Who Travel for Transplant in the United States

H. J. Braun, D. Amara, A. M. Shui, P. Stock, R. Hirose, F. Delmonico, N. L. Ascher, *University of California, San Francisco, San Francisco, CA*
Purpose: We have previously shown that United States (US) liver transplant (LT) candidates listed at a single center (SL) are disadvantaged compared with patients who travel for transplant—SL wait longer and have poorer post-transplant outcomes. SL compete for LT with multiply listed (ML) who are US citizens listed at more than one center, non-citizen, non-residents (NCNR) who travel to the US temporarily,

and non-citizen, residents (NC-R) who travel to and reside in the US. This study aimed to examine living donor liver transplant (LDLT) recipients only in order to determine the impact of traveler status on outcomes in this subset of LT recipients.
Methods: UNOS LT recipients from January 1, 2003-June 10, 2019 were reviewed, excluding re-transplant, pediatric, and multiple organ recipients. SL patients had one listing. ML patients had overlapping listing dates prior to transplant. NCNR and NC-R patients were defined by citizenship. Demographics were compared using descriptive statistics. Graft and patient survival were evaluated using the Kaplan Meier method and Cox PH.
Results: 75, 955 LT were performed during the study period, of which 3174 (4.1%) were LDLT. LDLT utilization in the four groups was significantly different (4.1% SL, 5.6% ML, 8.3% NCNR, 3.2% NC-R, p<0.001). There were significant demographic differences across the four groups in all variables except sex and match MELD (Figure 1). There was no significant difference in graft or patient survival when stratified by travel group (Figure 2). In a multivariable Cox model examining patient survival, only increasing age (HR 1.02, p-value<0.001) and presence of HCC (HR 1.59, p-value <0.001) were associated with increased risk of death after transplant.
Conclusions: LDLT is most frequently utilized in NCNR and ML. Our findings suggest that LDLT may serve a dual purpose: 1) enabling LT in patients who travel for transplant while supporting self sufficiency by leaving the deceased donor pool intact, 2) equalizing post-transplant outcomes among all groups. These results highlight a need to identify barriers to LDLT among SL, and remind us that live donor protection and safety remains of paramount importance as we advocate for expanded use of LDLT.

Abstract# 716

Medical Costs in the Year Following Kidney Transplantation: Relationships with Renal Function and Graft Failure

M. Cooper[1], M. A. Schnitzler[2], C. Nilubol[1], W. Wang[3], X. Zhu[3], J. Wu[3], R. J. Nordyke[4], *[1]MedStar Georgetown Transplant Institute, Washington, DC, [2]Saint Louis University, St. Louis, MO, [3]Genesis Research, Hoboken, NJ, [4]Angion Biomedica, San Francisco, CA*

Purpose: We describe relationships between total medical costs in the first year following kidney transplant with overall renal function as measured by: 1) estimated glomerular filtration rate (eGFR) at different time point during the first year, and; 2) early graft failure.
Methods: The United States Renal Data System was used to identify adults receiving single-organ deceased donor kidney transplants 2012-2015. Recipients without Medicare as primary payer were excluded. Costs derived from Parts A and B claims including inpatient, emergency, outpatient, and skilled nursing facility costs. eGFRs were available at discharge, 6-months, and 12 months. Thus, eGFR:Cost relationships are described for several month-based time periods post-discharge: 0-3, 3-6, 6-12, and 3-12. For recipients with graft failure a time-history of medical costs was constructed with failure as the index date. Descriptive analyses were conducted.
Results: For those without graft failure in the first year, total medical costs exhibit strong trends with eGFR in the post-discharge period. In the 3-6 months post-discharge, recipients with 6-month eGFRs of 30-59 mL/min/1.73m^2 have total costs 48% lower than those with <30 mL/min/1.73m^2. Both 6- and 12-month eGFRs correlate well with costs from 3 to 12 months post-discharge. Recipients with graft failure in the first year, monthly costs begin to rise 3-4 months prior to failure, with a spike of over $38,000 during the month of failure. Costs appear to stabilize 2-3 months post failure suggesting a months-long failure process.
Conclusions: Total medical costs in the first year post-transplant are strongly correlated with eGFR at various times post-discharge. Time histories of resource utilization indicate that graft failure in the first year is a very expensive process unfolding over several months.

Abstract# 717

A Payer's Perspective: The Cost of Hemodialysis versus Living Donor Kidney Transplant for Kidney Failure Patients in Nigeria

J. Lang[1], I. James[2], D. Da Rocha Afodu[1], C. G. Okwuonu[3], O. Ekwenna[1], *[1]University of Toledo College of Medicine and Life Sciences, Toledo, OH, [2]Surgical Specialists of Charlotte, Matthews, NC, [3]Department of Internal Medicine, Nephrology Unit, Federal Medical Centre, Umuahia, Abia State, Nigeria*

Purpose: To primarily quantify the costs of LDKT and HD in Nigeria from a 'payer's perspective' and secondarily inform future cost-effectiveness studies to guide health care decision-making of kidney disease management in the country.

Methods: This study was conducted from a payer (the ESRD patient) perspective in Nigeria. Due to scarcity of aggregate costing data, direct costs were determined through expert consultation, supplier pricing, and patient utilization data. Data was obtained from 53 patients who underwent HD at centers across Nigeria from July 2014 to June 2020, and 20 patients with ESRD who received a LDKT between June 2017 and May 2020. Due to limited availability of services within Nigeria, costs are mostly fixed with little variation. A transplantation specialist, transplant nephrologist, and transplant coordinator were consulted to verify input variables and costs, as well as clinical pathways in ESRD. One year and yearly recurring costs of LDKT and HD were determined, with HD costs projected for both three sessions per week and two sessions per week. Cost of transplant rejection was also quantified but not included in one-year or recurring costs. Costs were converted to USD.

Results: This cost comparison study demonstrated one-year costs of US $23,096.32 for HD (3 sessions per week) and $37,271.00 for LDKT. Yearly recurring costs were $22,394.32 for HD and $6,709.30 for LDKT. Costs of acute rejection for LDKT were $2,418.00 for antibody-mediated rejection and $1,170.00 for cell-mediated rejection. One-time costs dominated the one-year cost of LDKT at 82.0%, while alternatively 97.0% of one-year costs of HD were recurring costs. A discounted simulation (6% discount rate) of three-year costs when survival was assumed yielded a cost-savings of US $12,421.23 for LDKT in comparison to HD.

Conclusions: Costs of LDKT in Nigeria are higher than that of HD in the first year but are markedly decreased in subsequent years. The cost of HD and LDKT is primarily an out-of-pocket expense paid by patients with kidney failure in Nigeria. The maintenance cost of HD is three times more than the maintenance cost of immunosuppression post kidney transplantation. Our data demonstrates favorable long-term cost profile of LDKT vs. HD in Nigeria when cost is borne directly by patients. Further study of the comparative cost-effectiveness of these RRT modalities using survival data and outcomes is necessary.

Abstract# 1183

Association Between Cumulative Antithymocyte Globulin Dosing and Adverse Outcomes in Pediatric Heart Transplant Recipients

J. Chen[1], D. Salerno[1], H. Corbo[1], S. Shah[2], A. Rothkopf[3], I. D. Lytrivi[3], *[1]Department of Pharmacy, NewYork-Presbyterian Hospital, New York, NY, [2]College of Pharmacy and Health Sciences, St. John's University, Queens, NY, [3]Pediatric Cardiology, Columbia University Irving Medical Center, New York, NY*

Purpose: Lymphocyte depletion via rabbit antithymocyte globulin (rATG) is the most frequently used induction immunosuppressive in pediatric orthotopic heart transplant (OHT). Although outcomes are often reported based on the receipt of rATG or not, patient outcomes correlated to cumulative dosing of rATG are lacking.

Methods: Retrospective review of OHT recipients aged 0-21 years transplanted at a large pediatric transplant center from 1/2018-12/2019. rATG induction dosing was stratified into groups; Group 1 (<4.5 mg/kg), Group 2 (4.5-7.5 mg/kg), and Group 3 (>7.5 mg/kg). The primary outcome was cumulative incidence of acute cellular rejection (ACR) at 6 months. Secondary outcomes included cumulative incidence of infection (defined as CMV or EBV DNAemia > 100 copies), incidence of antibody-mediated rejection (AMR), and malignancy at 6 months post-OHT.

Results: 54 OHT recipients were identified who received rATG induction. Baseline demographics were similar between groups [Table 1]. The median age of the cohort was 8.8 (IQR, 3 - 15) years, 57.4% were male and 53.7% were Caucasian. In groups 1, 2, and 3, the cumulative incidence of ACR was 67.3%, 33.1% and 26.1%, respectively (P= 0.07) [Figure 1A]. The cumulative incidence of infection was 14.3%, 25.3%, 35.1% in groups 1, 2, and 3, respectively (P=0.792) [Figure 1B]. There was one episode of AMR in group 1 and one malignancy in group 2.

Conclusions: No associations between rATG dosing and acute rejection or infection were found. The cumulative incidence of rejection was numerically higher in the low-dose group 1. Further investigation into total weight-based rATG is warranted.

Abstract# 1184

The Perfect Candidate? The Stanford Integrated Psychosocial Assessment for Transplant

E. J. Henricksen[1], K. Stott[2], S. Ilango[2], Y. Moayedi[3], K. Waddell[4], H. I. Luikart[4], J. Twiggs[4], R. Lee[1], B. M. Zhang[5], W. Hiesinger[6], K. K. Khush[4], J. J. Teuteberg[4], *[1]Transplant, Stanford Healthcare, Stanford, CA, [2]Social Work, Stanford Healthcare, Stanford, CA, [3]Cardiology, University Health Network, Toronto, ON, Canada, [4]Cardiology, Stanford University, Stanford, CA, [5]Pathology, Stanford University, Stanford, CA, [6]Cardiothoracic Surgery, Stanford University, Stanford, CA*

Purpose: The Stanford Integrated Psychosocial Assessment for Transplant (SIPAT) is a tool used to objectify and enhance the pre-transplant psychosocial evaluation. We sought to assess whether the SIPAT score was associated with outcomes of acute cellular rejection (ACR), antibody mediated rejection (AMR) and graft survival after heart transplantation (HTx).

Methods: This was a retrospective analysis of HTx recipients from 01/2012 to 12/2019 at a single institution. Patients were excluded if a SIPAT was not performed prior to transplant or moved to a different transplant center within the first-year post HTx. Post transplant outcomes analyzed included ACR (2R or greater), AMR and graft survival, stratified by a SIPAT score under 20 (acceptable) versus 20 or greater (minimally acceptable). Kaplan-Meier estimator was performed for ACR, AMR and graft survival. Chi-square and t-test were performed to analyze differences in demographics between SIPAT categories.

Results: Overall 218 heart transplant recipients had a SIPAT evaluation. The median (IQR) SIPAT score was 15 (10-20.75) and 66 patients (30.3%) had a SIPAT score of 20 or greater. A SIPAT score of 20 or greater was not associated with an increased risk of graft loss (p-value = 0.6), ACR (p-value = 1), nor AMR (p-value = 0.2) (Figure 1). Female candidates (85.5% vs. 63.4%, p-value = 0.002) were more likely to have a SIPAT score under 20. Caucasians were also more likely to have a SIPAT score less than 20 (75.6% vs. 61.5%, p-value = 0.04). There was no difference in SIPAT scores for other baseline demographics.

Conclusions: Carefully selected patients with a "minimally acceptable" SIPAT score did not experienced an increased risk of graft loss, AMR or ACR. While the SIPAT tool has become an integral part of the HTx evaluation, a high SIPAT score alone may not be sufficient to decline HTx candidates.

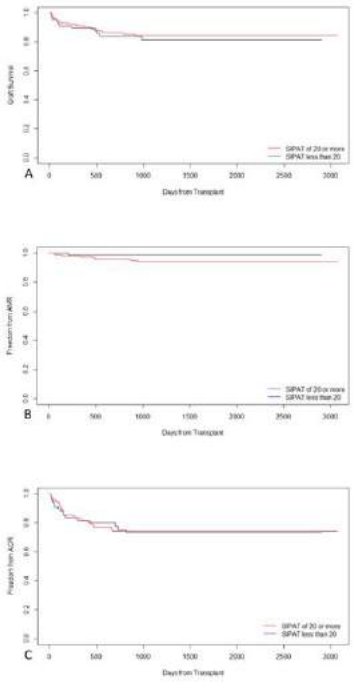

Figure 1. Comparison of SIPAT score of <20 (acceptable) vs. ≥20 (minimally acceptable candidate) for freedom from (A) graft failure, (B) antibody mediated rejection, and (C) acute cellular rejection 2R or greater.

Abstract# 1185

Intravenous Immunoglobulin in Heart Transplant Recipients with Hypogammaglobulinemia and Infection

J. Hoang, D. Nguyen, E. Graviss, M. Moaddab, A. Guha, J. Krisl, *Houston Methodist Hospital, Houston, TX*

Purpose: Hypogammaglobulinemia (HGG) is a complication of solid organ transplantation which has been associated with increased risk of infections. HGG is commonly defined as a serum immunoglobulin G (IgG) level <700 mg/dL. Intravenous immunoglobulin G (IVIG) replacement in patients with HGG may be able to reduce rates of infection; however, few studies have assessed the use of IVIG to reduce risk of recurrent infection for heart transplant recipients with HGG. The primary objective of this study is to describe the effect of using IVIG in patients with HGG and documented infections on the recurrence of infections within 6 months of the initial infection compared to patients with a documented infection who did not receive IVIG.

Methods: A single center, retrospective study was performed assessing heart transplant recipients transplanted from 2011 to 2020 admitted inpatient between October 2017 to May 2020 with a documented infection and serum IgG level <700. Patients were grouped based on those who did or did not receive IVIG during hospital admission. Patients were excluded if they received IVIG or other immune globulin products for indications other than HGG one month prior to the use of IVIG and HGG.

Results: Thirty-six patients were included in this study. Patients in the IVIG group received on average 1 dose of IVIG at 0.5 g/kg. Use of IVIG resulted in a significant median increase in serum IgG levels of 481 to 672 (p<0.001). Despite this observed increase, there were no differences in the primary outcome of recurrent infections at 6 months (4 vs 0, p=0.19) and similar recurrence when grouped based on severity of HGG. Additionally, there were no differences in the rate of recurrent and new infections at 3 and 12 months (see table). Severity of HGG was not a factor associated with recurrent infections within 6 months (p=0.32).

Conclusions: This cohort had a low number of recurrent infections. There were no differences observed between those who did or did not receive IVIG. Larger prospective studies are needed to confirm these findings.

Abstract# 1187

Right Ventricular Dysfunction After Heart Transplantation: When to Worry?

S. Kim, J. Patel, M. Kittleson, T. Singer-Englar, N. Patel, R. Skorka, D. Chang, E. Kransdorf, M. Hamilton, B. Azarbal, L. Czer, D. Ramzy, J. A. Kobashigawa, *Cedars-Sinai Smidt Heart Institute, Los Angeles, CA*

Purpose: Right ventricular (RV) dysfunction after heart transplantation (HTx) is not uncommon. The cause of RV dysfunction may be due to inadequate preservation, high pulmonary artery pressures, and extensive bleeding where high volumes of fluid are administered to the RV which begins to dilate. Recovery of RV dysfunction after HTx is not clear. There does not appear to be good biomarkers or hemodynamics that can predict easy recovery. The use of the pulmonary artery pulsatility index (PAPi) is defined as [(systolic pulmonary artery pressure - diastolic pulmonary artery pressure)/central venous pressure]. This is a novel hemodynamic index that can predict the severity of RV failure. It is not clear whether the use of PAPi can predict which patients would recover more rapidly from RV dysfunction.

Methods: Between 2010 and 2019, we assessed 33 HTx patients who developed RV failure, characterized by central venous pressure greater than 15 mmHg, pulmonary capillary wedge less than 15 mmHg, and echocardiographic RV function or dysfunction noted as moderate to severe. These patients were assessed for PAPi and followed by serial echocardiograms until RV function normalized. Correlation of PAPi to duration of RV dysfunction was recorded. PAPi was calculated at the time of established RV dysfunction, where PAPi value ≤1 was defined as abnormal. The time to recovery of RV function was correlated to PAPi as defined as normal versus abnormal.

Results: Abnormal PAPi patients compared to normal PAPi patients revealed a trend in longer time to recovery of RV dysfunction (111.3 vs. 36.3 days, p=0.071). This longer recovery time in the abnormal PAPi group persisted despite fewer patients with pulmonary hypertension. (See table.)

Conclusions: In HTx patients with RV dysfunction, the use of PAPi may be a prognostic marker for RV recovery and may even be a benchmark to determine if RV unloading with sildenafil may be appropriate.

Endpoints	Normal PAPi (n=24)	Abnormal PAPi (n=9)	P-Value
PAPi, mean ± SD	4.3 ± 3.5	0.33 ± 1.4	0.002
Recovery Time in Days, mean ± SD	36.3 ± 52.1	111.3 ± 182.0	0.071
Pulmonary Hypertension (%)	41.7% (10)	22.2% (2)	0.301

Abstract# 1188

Impact of Donor and Recipient Age Difference: Outcomes within the First Year of Orthotopic Heart Transplant

M. Mascetti, M. Manson, Z. Truman, *Baylor St. Luke's Medical Center, Houston, TX*

Purpose: In recent history, the number of patients listed as eligible to receive a heart transplant has increased by nearly 40%. However, not all hearts that are offered for donation are acceptable organs to be placed in recipients and the highest rates of rejected hearts were those from older donors. This study aims to determine whether donor and recipient age differences have an impact on transplant-associated adverse events within the first year post-transplant.

Methods: This was a retrospective, single-center, observational study conducted at CHI St. Luke's Health Baylor St. Luke's Medical Center (BSLMC) to determine incidence of graft survival one year post-heart transplant and transplant-related morbidity. Data were collected on adult patients who were transplanted at BSLMC from January 2012 to July 2019. Patients were excluded if they were lost to follow-up less than one year post-transplant, had a prior transplant or received dual organ transplantation. Patients were grouped based on differences in age between donor and recipient. Group 1 had donors older than recipients, Group 2 had donors 0 to 20 years younger than recipients, Group 3 had donors 21 to 40 years younger than recipients and Group 4 had donors over 40 years younger than recipients. Rejection was defined as biopsy-proven grades of at least 2R or greater or C4D positive based on the International Society for Heart and Lung Transplantation criteria.

Results: Information for 106 donors and recipients was included in this study, shown in Table 1 below. Results were considered significant for p-values less than 0.05. The only significant outcome was found in rates of antibody mediated rejection (AMR), with 25% of patients in Group 1 positive for AMR, compared to 27% in Group 2, 11% in Group 3 and 0% in Group 4. Of note, rates of death one year post-transplant were highest in Group 1 patients at 25% compared to only 6% in Group 2, 9% in Group 3 and 3% in Group 4.

Conclusions: This study demonstrated higher rates of rejection within the first year after a heart transplant in those recipients with older donors (Group 1) and recipients with donors less than 20 years younger (Group 2). Additionally, although not statistically significant, Group 1 patients demonstrated numerically higher death rates versus other recipient groups. However, given the limited sample size of Group 1, this study indicates that further research needs to be completed.

Abstract# 1189

Outcomes of HLA Antibody Surveillance Protocol in Heart Transplant Patients - A Single-Center Retrospective Analysis

S. S. Patlolla, V. Bhattad, S. McKean, M. Askar, S. Hall, *Baylor University Medical Center, Dallas, TX*

Purpose: Post-transplant care is multifaceted with protocols to provide oversight and maintain the standard of care. While institutional protocols for post-transplant HLA antibody surveillance after a positive virtual crossmatch (VXM) are often implemented, the impact on outcomes and survival is unclear. Our program implemented a protocol for antibody mediated rejection (AMR) surveillance for HLA donor specific antibodies (DSA) on post-transplant day 3 and 7 for patients with positive retrospective flow crossmatch (FXM), positive virtual crossmatch (VXM), DSAs present on VXM within 3 months, or DSAs newly detected on the serum sample tested for FXM.

Methods: Patients who received cardiac transplant between January 2018 and September 2020 in our center were retrospectively reviewed. Data was compiled to evaluate our protocol for DSA surveillance and survival at one-year post transplant. Multi-organ and re-transplant patients were excluded from the study.

Results: Of 143 eligible patients, 38 (27%) were positive for DSA at VXM. Of the 105 patients with negative VXM, 9 tested positive for DSA on sample used for FXM. Of those negative for DSAs on either crossmatch, only 8% developed DSAs by days 3 and 15% by day 7. Of those with DSAs on either crossmatch, 38% remained positive on days 3 and 7. Out of these patients, one was positive at day 3 with MFI increasing on day 7. Treatment for AMR was initiated on day 8. Only 18% of initially positive patients remained positive at 1 year. 21% were treated for rejection despite only 3% showing biopsy evidence of rejection. At 1 year, 91% of positive patients were alive.

Conclusions: Our findings suggest that patients positive for DSAs do not have inferior short-term outcomes compared to those negative for DSAs when early and serial HLA antibody testing was performed. This protocol allows early detection of DSAs and prompt management of potential rejection which could improve overall survival.

Abstract# 1190

Impact of a Pharmacist in an Outpatient Heart Transplant Clinic

A. Prom[1], D. Ricciuti[1], J. Newman[2], C. Doligalski[1], *[1]UNC Health Care, Chapel Hill, NC, [2]Eshelman School of Pharmacy, Chapel Hill, NC*

Purpose: Data describing the impact of a pharmacist in ambulatory medication management of heart transplant recipients (HTRs) is lacking. Following the addition of an ambulatory clinical pharmacist to the heart transplant team in 1/2017 we assessed outcomes at 1 year post-transplant of HTRs seen by a pharmacist compared to those not seen by a pharmacist at a single center.
Methods: A retrospective unpaired analysis of de novo HTRs from 1/2015-12/2019 was conducted. Dual organ, pediatric and HTRs who did not survive to discharge were excluded. Incidence of cardiac allograft vasculopathy (CAV), cellular and antibody-mediated rejection, all-cause rehospitalizations, all-cause mortality, attainment of goal blood pressure, hemoglobin A1c (A1c), tacrolimus level variability (CV) and use of aspirin and statin therapy were compared between pre and post pharmacist groups at 1 year post-transplant. No other personnel or protocol changes occurred during the study period. Chi-square and unpaired t-tests were used to conduct the analysis.
Results: 59 HTRs were included with an average of 12.2 ± 3.5 pharmacist visits per HTR in the pharmacist group. No differences in baseline demographics (Table 1) or maintenance immunosuppression (Table 2) were identified. At 1 year, the pharmacist cohort had a higher percentage of HTRs at goal blood pressure, on a statin, and on appropriate intensity statin (Figure 1), as well as fewer HTRs with any readmission and fewer total readmissions (Table 2). No differences in 1 year A1c control, tacrolimus CV, aspirin use, CAV, donor specific antibodies (DSAs), rejection or all-cause mortality were seen.
Conclusions: Based on this single center limited cohort study, pharmacist integration into an ambulatory heart transplant team has the potential to improve 1 year outcomes by targeting goal-directed medication therapy and reducing hospital readmissions.

Abstract# 1191

Geographic Variation in Candidate Listing Behavior Under the New Heart Allocation Policy

G. Ran[1], K. Chung[1], A. S. Anderson[2], R. Gibbons[3], N. Narang[4], M. Churpek[5], W. F. Parker[1], *[1]Pritzker School of Medicine, University of Chicago, Chicago, IL, [2]Department of Medicine, University of Texas San Antonio, San Antoion, TX, [3]Department of Medicine, University of Chicago, Chicago, IL, [4]Department of Medicine, University of Illinois-Chicago, Chicago, IL, [5]Department of Medicine, University of Wisconsin, Madison, WI*

Purpose: Describe and explain variations in listing practice among U.S. transplant centers in response to the new allocation policy.
Methods: We performed an observational cohort study comparing adult, heart-alone transplant candidates listed post-policy (December 2018 - February 2020) to a seasonally matched, pre-policy cohort (December 2016 - February 2018). We used mixed-effect logistic regression models to estimate each transplant center's expected and observed rate of high-priority status listing, and the association of pre-policy organ procurement organization (OPO) characteristics with the policy effect.
Results: Similar numbers of candidates were listed by U.S. transplant centers (N = 96) in each policy period (4,472 vs. 4,498). The average transplant center had greater odds of utilizing high-priority status than expected (OR: 6.34; 95% CI: 5.08-7.91), after adjusting for candidate characteristics. Ninety-one of 96 (94.8%) centers listed significantly more candidates at high-priority status than expected, with the unexpected increase varying from 4.8% to 50.4% (IQR: 14.0% - 23.3%). Compared with the average center, centers in OPOs with high rate of transplantation among high-priority candidates under the previous allocation scheme were significantly more likely to list candidates at high-priority status under the new policy (OR: 9.73, p = 0.01).
Conclusions: While listing behavior varied substantially between transplant centers in response to the new allocation policy, the utilization of high-priority statuses exceeded expectations in almost all centers. Widespread changes in transplant center practices may undermine the effectiveness of the new heart allocation policy.

Abstract# 1192

Combined Heart-liver Transplantation in Patients with Familial Amyloidosis - Analysis of Optn/Unos Database

A. Sharma, A. Sickels, B. Ruch, M. Carli, M. Levy, *Virginia Commonwealth University, Richmond, VA*

Purpose: We compared the outcomes after combined heart-liver transplant (CHLT) for patients with Familial Amyloidosis (FA) versus other indications (primary cardiac:congenital heart disease and idiopathic dilated cardiomyopathy; primary liver: cardiac cirrhosis and hepatitis C) in the United States.

Methods: We performed a retrospective review of the OPTN/UNOS database for patients who had undergone CHLT from October 1987 through April 2020. Patient survival and graft survival analyses (FA versus non-FA) were done using the R package ComparisonSurv, using the cloglog-transformed survival test of difference. Continuous variables were reported as mean (± standard deviation) or median (± IQR) and categorical variables were reported as counts/percentages. A p-value < 0.05 was considered significant.

Results: Between 1987 and 2020, 344 CHLT were performed [74 (21.5%) FA and 270 (78.4%) non-FA]. The FA patients were significantly older (58.7 vs 42.8 years, p<0.0001) and a majority were males (85% vs. 65.6%, p = *0.001).* FA patients trended towards shorter waitlist times (90.5 vs. 131 days, p = 0.07). There was no significant difference in the need for pre-transplant mechanical or ionotropic support. The 1- and 5-year patient survival for FA patients trended to be better than non-FA patients (91.6% vs 86.5%, p = 0.26 and 85.9% vs 79.5%, p = 0.27, respectively). However, this trend reversed towards inferior survival at 10-years (55.3% vs 68.6%, p = 0.16). Graft survival for both heart and liver followed similar trends at 1-, 5-, and 10-years, though not statistically significant.

Conclusions: In USA, CHLT recipients with familial amyloidosis are older but have excellent short-term outcomes compared to recipients transplanted for other indications. More research is needed to outline the reasons for a trend towards inferior long-term survival in CHLT recipients with FA.

Abstract# 1193

Simultaneous Heart-Liver-Kidney Transplantation Survival: National and Single-Center Outcomes

U. A. Siddiqi[1], P. S. Combs[1], G. Kim[2], T. Baker[3], Y. Becker[1], V. Jeevanandam[1], *[1]Section of Cardiac Surgery, University of Chicago Medicine, Chicago, IL, [2]Section of Cardiology, University of Chicago Medicine, Chicago, IL, [3]University of Chicago Medicine, Chicago, IL*

Purpose: Simultaneous Heart-Liver-Kidney transplantation (SHLKTx) is an incredibly rare, high-risk operation undergone by well-selected patients presenting with multi-organ failure. Our center has performed 10 of the 23 SHLKTxs to date. We compared survival and all-cause mortality in SHLKTx patients to those undergoing single- or double-organ heart transplants (HTx) on a national and single-center scale.

Methods: We performed a retrospective analysis of SHLKTx and HTx recipients from October 1987 to September 2020, using the UNOS Standard Transplant Analysis and Research database. A total of 80,039 HTx patients and 23 SHLKTx patients were included in our analysis. Of these, 660 and 10, respectively, were transplanted at our center. Survival and all-cause mortality were compared using Kaplan-Meier analysis and Cox regression.

Results: SHLKTx patients had worse baseline clinical status as they were more likely to be diabetic and possess elevated creatinine and serum total bilirubin levels (p <0.05 for all). These three factors were significant predictors of mortality in univariate and multivariate analyses (Multivariate HR: 1.215, 1.044, 1.015, respectively; p <0.0001 for all). However, post-transplant survival was comparable between patients undergoing SHLKTx and those undergoing single- or double-organ HTx on both national and single-center scales (p = 0.85 and p = 0.29, respectively). Furthermore, SHLKTx was not significantly associated with mortality in either national or single-center data, and there was a non-significant trend towards improved survival in our center's SHLKTx patients compared to our center's HTx patients and SHLKTx patients from other centers.

Conclusions: Current data indicates that patients undergoing SHLKTx experience survival and mortality outcomes comparable to those undergoing single- or double-organ heart transplants at both national and single-center levels. Our findings are limited by a lack of long-term follow-up and the rarity of SHLKTx. Further studies are needed to investigate other clinically significant outcomes such as rejection and infection.

Abstract# 1194

Primary Graft Dysfunction in a Risk-Stratified vs. Routine Induction Protocol in Heart Transplant Recipients

J. S. van Zyl[1], H. Zafar[1], P. M. Nguyen[2], J. Felius[1], T. Sam[3], S. A. Hall[3], *[1]Baylor Scott & White Research Institute, Dallas, TX, [2]Texas A&M University College of Medicine Health Science Center, Dallas, TX, [3]Baylor Scott & White Health, Dallas, TX*

Purpose: Treatment of left ventricular primary graft dysfunction (PGD-LV) is supportive in nature. We aim to evaluate whether a change in induction protocol from a routine to risk stratified (RSI) approach resulted in a change in prevalence of PGD-LV or inotrope score.

Methods: We retrospectively reviewed consecutive first-time heart transplant recipients between January 2015 and February 2019. PGD-LV was graded according to the ISHLT-2014 criteria. Survival and biopsy-proven acute cellular (ACR≥2R) and antibody-mediated rejection (pAMR>0) were assessed to 1 year post-transplant. Baseline recipient and donor characteristics, and PGD-LV were compared between protocols using chi-square, Fisher Exact, Wilcoxon, and t-tests. Rank-based analysis of covariance was used to compare inotrope score adjusted for confounders. Time to event outcomes were analyzed using Cox proportional hazard models adjusted for moderate-severe PGD-LV.

Results: Of 235 recipients, 115 followed a routine induction protocol and 120 the RSI protocol implemented in 2017. In the routine group, 111 (97%) were treated with Basiliximab and 4 (3%) with Anti-thymocyte globulin (ATG); whereas 17 (14%) received Basiliximab, 2 (2%) ATG and 101 (84%) no induction therapy in the RSI group. Baseline recipient and donor characteristics were similar, except significantly higher mean arterial pressure (median [Q1-Q3]: 87 [81 - 97] vs. 83 [76 - 90] mmHg; p=0.01), fewer donors with left ventricular hypertrophy (LVH) (11% vs. 26%; p=0.008) and lower ischemic time (median [Q1 - Q3]: 179 [136, 225] vs. 209 [169, 247] min; p<0.001) in the RSI cohort. The prevalence of PGD-LV was similar (RSI vs. routine: 17% vs. 18%; p=0.88) and was composed of 23 mild, 6 moderate and 12 severe cases. In contrast, the median [Q1-Q3] inotrope score of 11 [7-14] in the RSI group was lower compared to 12 [9-17] in the routine group (p=0.02) which remained significant adjusting for donor LVH and ischemic time. The risk of mortality and of rejection between RSI and routine cohorts were similar when adjusting for moderate-severe PGD (p=0.81 and p=0.99; Fig.1).

Conclusions: The RSI approach was associated with a reduction in induction therapy usage without an increase in PGD-LV. Risk of rejection and mortality adjusting for PGD-LV severity appears comparable between induction strategies. Moreover, a small reduction in the inotrope score was observed in the RSI cohort warranting further investigation.

Abstract# 718

Risk Factors Associated with Severe COVID19 Illness in Kidney Transplant Recipients

E. Abuhelaiqa, M. Alkadi, H. Tohid, R. Elidrisi, R. Abdul Rahiman, M. F. Elshirbeny, T. A. Ghonaimi, A. I. Hamad, A. Nauman, A. A Aziz, O. Fituri, M. Asim, M. A. Othman, H. Al-Malki, *Hamad Medical Corporation, Doha, Qatar*

Purpose: COVID19 is an acute respiratory infection that is caused by the SARS-COV-2 that has been shown to be highly contagious and poses a significant mortality risk. Kidney transplant recipients are shown to be at increased risk of acquiring and developing a severe form of the disease compared to the general population. There is limited evidence to guide the transplant community on methods to reduce disease severity. We aim to evaluate risk factors associated with severe [requiring hospitalization] or critical [requiring ICU care] COVID-19 illness in kidney transplant recipients.

Methods: We evaluated kidney transplant recipients with COVID19 between February to August 2020. Among 748 recipients followed at our center, 43 recipients (5.7%) were diagnosed with COVID19 infection through nasopharyngeal swab PCR. Of those, 9 patients were treated within an isolation facility, 25 patients admitted to the hospital and 9 patients were admitted to the intensive care unit (ICU). We evaluated demographic, clinical and laboratory factors to evaluate severity of illness by using Kruskal-Wallis for continuous variables and chi square test for categorical.

Results: Older age was associated with ICU admission (57 vs. 53 vs. 45 P=0.03) while gender, ethnicity and type of transplant were similar between the three groups (Table 1). In addition, CNI level, MMF dose or base line creatinine was not significantly different between the three groups. Presentation with fever, shortness of breath and hypoxia were more frequent in ICU group. Laboratory findings of lymphopenia, low Albumin, high CRP and high procalcitonin at presentation were also more frequent in ICU group. Treatment with hydroxychloroquine, Oseltamivir, Ritonavir, Azithromycin, and reduction of immunosuppression were more frequent in ICU (table 2). We observed 14 patients with graft dysfunction and majority were in ICU group. Furthermore, in the ICU group, 3 recipients required renal replacement therapy and of those there was a single death.

Conclusions: Severity of COVID19 infection is variable among our transplant population. Prognostication of COVID19 severity in kidney transplant recipient is crucial for early recognition of critical illness and may offer the benefit of early therapy such as antiviral or immunosuppression reduction in this high-risk group.

Abstract# 719

Clinical Outcomes of Solid Organ Transplant Recipients with Severe Acute Respiratory Syndrome Coronavirus 2

R. Adekunle, D. Jandhyala, J. Lewis, *Medicine, Division of Infectious Diseases, Medical University of South Carolina, Charleston, SC*

Purpose: The Centers for Disease Control and Prevention identified solid organ transplant (SOT) recipients as persons at high risk to develop severe illness secondary to Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2). We reviewed the clinical characteristics and outcomes of SOT recipients who had SARS-CoV-2 at our center.

Methods: This was a retrospective review of SOT recipients diagnosed with SARS-CoV-2 between March 1st 2020 and September 31st 2020 in the Medical University of South Carolina (MUSC) Health Care system. Subjects were included if they had undergone SOT at any time prior to a positive SARS-CoV-2 PCR. Descriptive statistics were used to analyze demographic and clinical characteristics. Primary outcomes included need for hospitalization, complications, and estimated all-cause mortality.

Results: 51 SOT recipients were diagnosed with SARS-CoV-2. Five patients were excluded as they initially tested positive and were admitted to another facility. 46 SOT recipients were analyzed, of which, 31 (67%) were hospitalized. Of those hospitalized, 45% were males, 68% were black and 71% were kidney transplant recipients. Median length of stay was three days (range 0.6-108.6). 10 (32%) patients required supplemental oxygen and 6 (19%) received care in the intensive care unit. Complications, including bacterial infections (16%), fungal infections (3%), CMV reactivation (6%), and rejection (3%) were rare. One patient (2%) died during the study time period.

Conclusions: The majority of SOT recipients with SARS-CoV-2 in our cohort required admission, however they experienced few complications and a low mortality, despite their high-risk status.

Table 1. Clinical data for 31 hospitalized solid organ transplant recipients

Abstract# 720

Outcomes of Lung Transplantation with Multi Drug Resistant Colonized Grafts, Retrospective Cohort Study in a Tertiary Care Hospital

N. Al-Ashi, *Pharmacy, King Fahad Specialist Hospital -Dammam, Khobar, Saudi Arabia*

Purpose: Infections are the primary cause of morbidity and mortality after solid organ transplantation. Due to high incidence of lung graft colonization with multi drug resistant organisms, King Faisal Specialist Hospital & Research Center upgraded their antibacterial prophylaxis protocol to include colistin, meropenem and vancomycin. Our aim is to evaluate the safety and efficacy of this regimen in reducing the incidence of donor derived infections and improving patient and graft survival post lung transplantation.
Methods: Retrospective case control study, included all adult lung transplant recipients with multi drug resistant colonized grafts who underwent lung transplantation from 2010-2019 (study group) compared to those in the same time period without multi-drug resistant colonization (control group). Pediatrics, multi-organ transplantat recipients, and patients who died within 24-hours due to technical reasons will be excluded. The primary outcome was the rate of donor derived bacterial infections in the first month post lung transplantation. Secondary outcomes included graft and patient 6- and 12-month survival, ECMO requirement post transplantation, rate of re-hospitalization in the first 6 months post transplantation, and safety outcomes (acute kidney injury, neurotoxicity and clostridium difficile infection). A non-inferiotity analysis for the differences between the groups in primary and seconday outcomes will be conducted, with regression analysis to assess the effect of different baseline variables on the outcomes.
Results: Preliminary analysis of 31 patients (16 in study group and 15 controls), patients in the study group were younger than the control group (36.75±11.34 vs. 41.60±14.85 years; p=NS). The most common indication for lung transplantation is idiopathic interstitial pneumonia (control 40% and study 31.25%). Donor-derived infections occurred in 10 patients in the study group (62.50%) vs. 8 of the control (53.33%); p= NS. Patients in the study group required approximately 5 times more ECMO post-transplantation than controls. Six- and 12- month survival was 100% in both groups.
Conclusions: As expected, numerically, the rate of donor deriver infections is higher in the study group. However, conclusions cannot be drawn until complete analysis of study cohort.

Abstract# 722

Risk Factors and Outcomes of Neutropenia in Kidney Transplant Recipients

R. Avery[1], J. Motter[1], S. Sae-Tia[2], N. Lu[1], W. Cochran[1], A. Massie[1], D. Brennan[1], F. Akinwande[1], S. Shoham[1], E. Kraus[1], N. Alachkar[1], S. Alasfar[1], F. Naqvi[1], F. Al Ammary[1], K. Marr[1], S. Mehta Steinke[1], N. Desai[1], O. Ezennia[1], P. Plummer[1], C. Durand[1], W. Werbel[1], M. Y. Kim[1], D. Segev[1], J. Garonzik Wang[1], B. Trollinger[1], L. Lees[1], L. Toman[1], S. Shulder[3], K. Dzintars[1], D. Ostrander[1], *[1]Johns Hopkins, Baltimore, MD, [2]Stony Brook University, Stony Brook, NY, [3]University of Rochester, Rochester, NY*

Purpose: Neutropenia is a common side effect of valganciclovir and may pose increased risk for post-transplant infections. Medications such as mycophenolate and infections such as CMV also contribute to neutropenia risk. We sought to determine the incidence of infections in patients who did or did not develop neutropenia post-transplant.
Methods: Of 1076 kidney transplant recipients at our center from 2010-2014, we identified 393 patients (36.5%) who had developed neutropenia at any time post-transplant (ANC < 1000 cells/mm^3, "neutropenic group"), and 683 (63.5%) who never developed neutropenia ("non-neutropenic group"). Data were collected on demographics, transplant characteristics, immunosuppression, and infections over 3 years post-transplant. Mild outpatient infections were excluded. We used multivariable Poisson regression to evaluate the association between neutropenia and rate of infection.
Results: Most common infections were urinary tract (in 34.5% overall), CMV (17.8%), pulmonary (17.5%), and bloodstream (12.5)%; all of these were more common in the neutropenic group (p for all < 0.02). In the neutropenic group, 34.2% had CMV DNAemia at some point, vs. 8,4% in the non-neutropenic group (p<0.001). Neutropenic fever occurred in 3.6% of the neutropenic group. Bloodstream infections occurred in 16.8% of the neutropenic group vs 10% of the non-neutropenic group (p=0.001).
Conclusions: The development of neutropenia at any time post-transplant identifies a group with an increased incidence of infections, compared to patients who never develop neutropenia. Causality is complex since infections may either result from, and contribute to, neutropenia. Further studies will be important in designing strategies for prevention of post-transplant neutropenia and associated infections.

Abstract# 723

Practice Patterns in Pneumocystis Jirovecii Pneumonia Prophylaxis in Solid Organ and Bone Marrow Transplant Recipients

S. Cao, K. Khalil, F. Cirrone, S. Mehta, *NYU Langone Transplant Institute, New York, NY*

Purpose: Trimethoprim-sulfamethoxazole (TMP-SMX) is the preferred agent for pneumocystis jirovecii pneumonia (PJP) prophylaxis in solid organ transplant (SOT) and bone marrow transplant (BMT); however, adverse effects may lead to the use of alternative agents. We sought to characterize the rate and reason for using alternative agents for PJP prophylaxis in SOT and BMT recipients over an 18-month period at a single institution to guide stewardship.

Methods: SOT and BMT patients between 2/1/2018 and 8/1/2019 were included. 455 SOT and 126 BMT patients were identified and included in the final analysis; 1 SOT and 2 BMT patients were excluded due to expiration prior to initiation of PJP prophylaxis. Electronic medical records were retrospectively reviewed for initial PJP prophylaxis choice, change of initial prophylaxis, and reason for change.

Results: Among 454 SOT and 124 BMT recipients, most (90.1%) patients received initial prophylaxis with TMP-SMX, followed by atovaquone (9.9%). In SOT recipients, the primary reason for an initial or subsequent switch to an alternative regimen was elevated creatinine or potassium. In BMT recipients, the primary reason was cytopenias. Among patients who were switched to an alternate regimen, 34 (41%) SOT recipients and 3 (12%) BMP recipients were switched back to TMP-SMX. Among patients who were initiated on an alternate regimen, 28 (59.6%) SOT recipients and 1 (9.1%) BMT recipient were switched to TMP-SMX. Mean number of days to TMP-SMX regimen interruption was 42 days in SOT recipients and 107 days in BMT recipients (p=0.005).

Conclusions: While most SOT and BMT recipients received TMP-SMX for PJP prophylaxis, alternate agents were used primarily in the setting of concern for renal and hematologic adverse effects. Patients should be monitored for recovery of renal function and cell counts to evaluate the appropriateness of switching back to TMP-SMX.

Table 1. Demographics

Variable	N	%
Solid organ transplant	454	
Average age at transplant	56.28	
Type of transplant		
Single organ	429	94.5%
Heart	49	10.8%
Kidney	263	57.9%
Delayed graft function	78	29.7%

Abstract# 724

Cryptococcosis in Renal Transplant Recipients —An Analysis of United States Renal Data System Data

M. E. Cervera-Hernandez, H. A. Yoon, L. Pirofski, V. Hemmige, *Montefiore Medical Center, Bronx, NY*

Purpose: Solid organ transplant recipients are at increased risk for cryptococcosis, which is known to decrease their survival. Adherence to recommended management strategies and outcomes in this population have primarily been researched in single-center or small multicenter studies. The purpose of our study is to utilize an extensive dataset of end-stage renal disease patients in the United States, the United States Renal Data System (USRDS), to describe cryptococcosis in kidney transplant recipients.

Methods: We analyzed demographic, transplant, and hospitalization data of USRDS renal transplant recipients first hospitalization for cryptococcosis after transplantation in the period from January 2010 to December 2016.
Results: The dataset contained information for 1,204,196 hospitalizations in 213,070 kidney transplant recipients. Among them, we identified 952 patients who had 2,193 cryptococcosis hospitalizations. The median time from the earliest transplant to first cryptococcosis hospitalization was 3.5 years (IQR 1.3-8.6). The mean number of hospitalizations per patient was 2.3, and the median length of stay for the index hospitalization was 11 days. Forty-four percent of patients had admission to an intensive care unit during their first hospitalization with a mean length of stay of 5.5 days. During the index hospitalization, 66% of patients had one or more lumbar punctures. The 30- and 90-day readmission rate after index hospitalization was 33.6% and 43.2%, respectively. Seventy-seven patients (8%) died during the index hospitalization.
Conclusions: Cryptococcosis is an important contributor to morbidity and mortality among kidney transplant recipients. In future research, we intend to use provider, drug, and claims data to study patterns of care preceding cryptococcosis diagnosis and its long-term impact.

Characteristics of Renal Transplant Recipients with Cryptococcosis During First Hospitalization

Characteristic	Cryptococcosis N (%)	Alive N (%)	Died N (%)	P
Male	634 (66.6)	580 (66.2)	54 (70.1)	0.4*
Age at diagnosis, years, mean (IQR)	60.1 (53.3-68.2)	59.9 (53.2-68.1)	62.3 (55.5-69.8)	0.07**
Time posttransplant, years, median (IQR)	3.5 (1.3-8.6)			
Lumbar punctures	629 (66)	579 (66.1)	50 (65.9)	0.8*
Lung procedures	250 (26.2)	222 (25.3)	28 (36.3)	0.036*

Abstract# 725

Use of Microbial Cell Free DNA Sequencing in Solid Organ Transplant Patients

S. Chang, P. Gaynor, A. Multani, O. E. Beaird, M. Carlson, S. Yang, O. Garner, J. Schaenman, *University of California, Los Angeles, Los Angeles, CA*

Purpose: Microbial cell free DNA (cfDNA) sequencing has emerged as a new noninvasive tool for the diagnosis of infectious diseases in recent years, but its diagnostic utility remains in question. We sought to assess this by characterizing its usage in solid organ transplant (SOT) patients.
Methods: We performed a retrospective chart review of all SOT patients who had microbial cfDNA sequencing done from 2016-2020.
Results: There were 17 adult SOT patients who underwent microbial cfDNA sequencing, including 6 kidney, 3 lung, 5 liver, 2 intestinal, and 1 heart transplants. Presentations that prompted testing included systemic, neurologic, sinuses, pulmonary, skin, gastrointestinal, and combinations of the above (see Table). Positivity rate for microbial cfDNA sequencing was 12/17 (70.6%), with a sensitivity of 66.7%. The highest positivity was found in patients who had systemic, neurologic, and sinus infections. Of the positive tests, 2 led to a change in either management or diagnosis (2/12, 16.7%). One of the two cases was a kidney transplant patient with disseminated histoplasmosis in which the cfDNA sequencing preceded positive cultures by 12 days. The second case was a liver transplant patient who was diagnosed with Aspergillus endocarditis based on the cfDNA sequencing result when conventional lab methods resulted negative. The remaining 10 cases with positive sequencing results did not lead to changes in management nor diagnosis due to either earlier results via conventional lab methods or lack of clinical correlation.
Conclusions: In this solid organ transplant cohort, microbial cfDNA appeared to have highest positivity rate in select group of patients, and led to clinical changes in 16.7% of cases. Given the importance of early and accurate diagnosis in immunocompromised patients, cfDNA based diagnostics hold promise as a method for noninvasive testing. Future studies will explore the strengths and limitations of this testing approach in different clinical scenarios to better delineate appropriate testing algorithms.

Table. Presentation, positivity rate, and final diagnoses of SOT patients. CMV=cytomegalovirus; VZV=Varicella zoster virus; M.=Mycobacterium.

Presentation	Positivity %	Diagnosis	Clinical Impact
Systemic + Pulmonary (2)	2/2, 100%	Disseminated histoplasmosis Aspergillus endocarditis	Change of management
Systemic + Skin (2)	1/2, 50%	Medication induced fever Disseminated *M. haemophilum*	No impact
Systemic + Cardiac (1)	1/1, 100%	Disseminated *M. tuberculosis*	No impact
Systemic (2)	2/2, 100%	Disseminated *Nocardia brasiliensis* Intraabdominal infection	No impact
Neurologic (1)	1/1, 100%	Disseminated VZV infection	No impact
Sinuses (1)	1/1, 100%	Invasive rhino-orbital fungal infection	No impact
Pulmonary (4)	2/4, 50%	Pneumonia Unspecified pulmonary infection Pleural effusion Pleural effusion	No impact
Skin (1)	0/1, 0%	*M. chimera* surgical site infection	No impact
GI (3)	2/3, 67%	Hepatic necrosis CMV hepatitis Acute cellular rejection	No impact

Abstract# 726

Comparison of Outcomes in Sot Recipients During Two Eras of Covid-19 Therapeutics

T. Chiang, A. Sait, A. Massie, K. Marr, D. Brennan, W. Cochran, P. Shah, T. Jain, S. Mehta Steinke, N. Desai, N. Permpalung, S. Shoham, C. Merlo, C. Durand, W. Werbel, M. Dioverti, D. Ostrander, A. Gurakar, M. Y. Kim, J. Garonzik-Wang, D. Segev, R. Avery, *Johns Hopkins University, Baltimore, MD*

Purpose: COVID-19 therapies have evolved over time, but little is known regarding outcomes in SOT recipients treated with newer therapeutic agents such as remdesivir, dexamethasone, and convalescent plasma. We sought to compare outcomes including mortality, rejection, and renal function in a retrospective cohort of SOT recipients with COVID-19 treated during two different eras of therapy.
Methods: 40 SOT recipients hospitalized for COVID-19 at our center comprised Era 1 (Mar- May 2020, 20 patients) and Era 2 (Jun - Aug 2020, 20 patients). Data were collected on demographics, comorbidities, renal function, and mortality at time points out to 90 days after COVID-19 infection.
Results: Patients in Era 1 received hydroxychloroquine (11/20, 55%), tocilizumab (5/20, 25%) and/or convalescent plasma (3/20, 15%) as targeted therapy; patients in Era 2 received primarily remdesivir (8/20, 40%), dexamethasone (6/20, 30%), and/or convalescent plasma (13/20, 65%). Mortality was 1/20 in Era 1 and 0/20 in Era 2. MMF was held in 33/35 (94%) of patients. Acute kidney injury was present on presentation in 14/40 (35%). The median (IQR) decrease in SCr (mg/dl) between admission and last followup was 0.5 (0.4-0.6) and 0.1 (0-0.4) in patients who had and had not received remdesivir, respectively (p=0.02), 0.5 (0.1-0.6) and 0.1 (0-0.3) in patients who had and had not received plasma, respectively (p=0.09). Antibody-mediated rejection (AMR) occurred in 2 patients in Era 1 and 0 patients in Era 2. Acute cellular rejection (ACR) occurred in 1 patient in Era 1 and 0 patients in Era 2.
Conclusions: SOT recipients treated in Era 2, when the major targeted therapies were remdesivir, dexamethasone, and convalescent plasma, were not at higher risk for renal dysfunction, ACR, or AMR in the aftermath of COVID-19; rejection was uncommon in both eras and mortality was low in both eras. While awaiting detailed safety studies, these results suggest against renal toxicity or triggering of alloimunity in those receiving newer therapies.

Abstract# 727

Clinical Consequences in Patients Experiencing Leukopenia and Neutropenia After Solid Organ Transplant

A. Diamond[1], N. Diehl[2], K. Hiryak[3], K. Mortia[1], J. Au[1], C. Ruggia-Check[1], H. Clauss[4], *[1]Pharmacy, Temple University Hospital, Philadelphia, PA, [2]Pharmacy, UPMC Pinnacle Health, Harrisburg, PA, [3]Pharmacy, Temple University School of Pharmacy, Philadelphia, PA, [4]Infectious Diseases, Temple University Hospital, Philadelphia, PA*

Purpose: The incidence of leukopenia and neutropenia in solid organ transplant (SOT) recipients can be influenced by medications required after transplant for immunosuppression and infection prophylaxis. This may lead to providers altering doses of immunosuppressant and infection prophylaxis medications which may increase the risk of clinical consequences such as graft rejection, mortality, and infections. Further research is warranted to assess the incidence of clinical consequences in patients developing cytopenias within 12 months of transplant.

Methods: This retrospective, single center chart review performed at our institution included patients 18 to 89 years old who received a SOT between August 2016 to November 2017. The primary endpoint was the incidence of clinical consequences between groups within 12 months after transplant. Secondary endpoints included cumulative days of mycophenolate dose reduction or discontinuation as well as mycophenolate and valganciclovir dose adjustments in response to a cytopenic event.

Results: Out of the 179 records included, the most common type of organ transplant was lung and kidney. No differences in induction and maintenance immunosuppression were noted between groups. A trend towards lower monthly total mycophenolate doses was observed in the leukopenia only and neutropenia groups. No differences in acute rejection (13.5% vs. 13.6% vs. 14.4%; p=0.879), bacterial infection (56.8% vs. 67.8% vs. 51.8%; p=0.161), or patient survival (97% vs. 100% vs. 97%; p= 0.254) were noted between groups. Prescribers commonly held or decreased the dose of mycophenolate while continuing valganciclovir in response to an episode of cytopenia. Patients with neutropenia more frequently developed cytomegalovirus (CMV) infection than other groups (2.7% vs. 23.7% vs. 9.6%; p=0.006) after the event, however only 1 patient developed CMV infection after holding valganciclovir.

Table 1

	Leukopenia only (N= 37)	Neutropenia (N= 59)	Neither leukopenia or neutropenia (N= 83)	p-value
Age (years), median [IQR]	63 [50-69.5]	65 [57-71]	64 [52-69]	0.409
Male gender, n (%)	29 (78.4)	31 (52.5)	58 (69.9)	0.020
Type of transplant, n (%) Kidney; Single lung; Double lung	12 (32.4); 13 (35.1); 7 (18.9)	10 (16.9); 26 (44.1); 14 (23.7)	20 (24.1); 26 (31.3); 22 (26.5)	0.139
Mycophenolate held at event, n (%)	12 (32.4)	21 (35.6)	--	--
Cumulative days of mycophenolate dose reduction or discontinuation, median days	43	73	--	--
Valganciclovir continued at event, n (%)	33 (89)	39 (65)	--	--

Conclusions: This data may suggest that holding or decreasing mycophenolate for a moderate duration in our population did not increase the rate of acute rejection. The occurrence of a leukopenic or neutropenic event did not appear to increase the rate of bacterial infection, but close monitoring for CMV infection may be warranted.

Abstract# 728

Influence of Immunosuppressant Management on Mortality in Kidney Transplant Recipients Hospitalized with COVID-19

Y. Fenig, A. Santeusanio, M. Menon, C. Liu, M. Rana, R. Shapiro, *Mount Sinai Hospital, New York, NY*

Purpose: Kidney transplant recipients are thought to be at high risk for mortality from COVID-19 due to the necessity for chronic immunosuppressive therapy to prevent graft rejection. However, the optimal immunosuppressant management strategy for patients with COVID-19 remains unknown.

Methods: We conducted a single-center, retrospective review of all kidney or kidney-pancreas transplant recipients with a functioning graft who were hospitalized with COVID-19 between 3/15/2020-5/15/2020. Patients were followed from the date of admission, up until 1 month following hospital discharge or study conclusion (6/15/2020). Multivariable logistic regression was used to identify potential patient or immunosuppression characteristics associated with the development of severe COVID-19 and in-hospital mortality.
Results: 69 (3.2%) patients followed longitudinally at our center were hospitalized with COVID-19 during the review period, 38 of whom were admitted to the study institution. Patients were ethnically diverse, and the majority were receiving tacrolimus (84.2%), mycophenolate (89.5%), and corticosteroids (81.6%) at baseline. Following COVID-19 diagnosis, median tacrolimus trough levels decreased by -11% (-26%-+17%) during hospitalization and mycophenolate doses were reduced by at least 50% in 33 patients. Adjunctive therapy included hydroxychloroquine (68.4%), convalescent plasma (26.3%), anticoagulation (52.6%), and participation in clinical trials (10.5%). Twenty patients developed severe disease, and 11 (28.9%) died during hospitalization. Admission characteristics associated with increased risk for mortality included age (OR=2.0; 1.0-4.0) and history of HIV (OR=22.6; 1.1-483.7). No association was found between baseline tacrolimus trough levels, mycophenolate dosing, or the number of immunosuppressants prescribed and COVID-19 mortality. Similarly, the degree of immunosuppression reduction following hospital admission was not associated with survival or severe disease progression. No differences were observed in the prescription of adjunctive therapies, with the exception of a higher daily dose of prednisone equivalents in patients who died (37.0 vs 15.4; p=0.02). Among survivors, death-censored allograft survival was 96.2% at 1-month, and no cases of biopsy proven rejection were observed during the review period.
Conclusions: The findings from our study confirm age as a significant risk factor for COVID-19 mortality in kidney transplant recipients, and suggest HIV status as an additional risk factor that may warrant further investigation. Pre-emptive immunosuppression reduction does not appear to be warranted, as baseline immunosuppression intensity and dose modulation following diagnosis of infection were not associated with hospital outcomes. However, no episodes of acute rejection were observed, so providers may wish to consider immunosuppression reduction on a case-by-case basis.

Abstract# 729

Pulmonary Infections in Patients with Kidney Transplant: Epidemiology, Risk Factors and Impact of a Dedicated Pre-Transplant Infectious Disease Consultation

E. Feredj, *Infectious Disease, APHP Henri Mondor, Créteil, France*

Purpose: We aim to describe the spectrum of pulmonary infections after kidney transplant, to identify risk factors and to evaluate the impact of pre transplant infectious consultation for vaccination updates and infection prevention.
Methods: We included patients with kidney transplant performed between 2015 and 2019 in a retrospective monocentric cohort study. Multivariate analyses were performed to assess the risk factors of pulmonary infections and mortality after kidney transplant.
Results: 516 renal transplant patients were included, of which 145 had received pre-kidney transplant infectious disease consultation. We identified 123 pulmonary infections including 75 pneumonias in 95 patients at a median of 5 months post-kidney transplant. Bacterial infection was responsible for the majority of pulmonary infections (n=31), with a predominance of gram-negative bacteria (n=23). Immunosuppressive therapy had no impact on the occurrence of pulmonary infections. In contrast, independent risk factors were chronic infection with the human immunodeficiency virus (HIV) or hepatitis C virus (HCV), the presence of DSA prior to transplantation, the recipient's age, and combined transplants. Inversely, an infectious disease consultation prior to kidney transplant was found to be a pulmonary infections-independent protective factor ($p = 0.033$). Importantly, pulmonary infections had an adverse impact on patient survival ($p < 0.0001$).
Conclusions: By conducting a retrospective monocentric study, we describe the spectrum of pulmonary infections after renal transplantation. Pulmonary infections after renal transplant impact patient survival. Systematic infectious disease consultation was an independent protective factor.

Abstract# 730

Clinical Characteristics and Outcomes of Aspergillus Infections in Intestinal Transplant Patients: Retrospective Cohort Study

A. Fernandez, M. Romero, Y. Natori, J. Camargo, S. Anjan, R. Vianna, J. Simkins, *Miami Transplant Institute, Jackson Health System, Miami, FL*

Purpose: *Aspergillus* infection is the most common mold infection in solid organ transplant recipients and its consequences can be fatal. Data in intestinal transplants (ITx) recipients is scarce. In this study, we compare the clinical characteristics and outcomes of ITx recipients with and without invasive aspergillosis (IA) at a large transplant center.
Methods: Single-center, retrospective cohort-study of ITx performed between January 2009 to October 2019. The patients were followed until October 2020. We determined the incidence of IA in our cohort. We assessed if there were any differences in demographics, type of ITx, IA risk factors (ICU stay prior to ITx, retransplantation, reoperation within 1 month of ITx), and one-year mortality and proven-biopsy rejection between those ITx recipients with and without IA. In addition, we evaluated for risk factors, treatments and outcomes for those who were diagnosed with IA.
Results: Seventy-eight adult patients underwent ITx. Seven were excluded due to peri-transplant mortality. Therefore, 71 patients were included. The incidence of IA in our cohort was 8.5 per 100 transplanted patients. There were no differences in demographics, IA risk factors and one-year mortality and rejection between both groups (Table 1). Most of the IA cases were pulmonary, occurred within 6 months of ITx and were treated with voriconazole. The IA was cured in four (66.7%) of the patients (Table 2).
Conclusions: Our ITx cohort demonstrated a high incidence of IA. Larger studies are needed to determine the risk factors associated with IA in this transplant population.

Abstract# 731

Utilizing Risk Factors to Guide Prevention of Invasive Fungal Infections in Liver Transplant Recipients

K. Fitton, A. Chan, C. Truax, B. Sirandas, T. Larson, L. Smith, A. Carlson, *University of Utah Health, Salt Lake City, UT*

Purpose: Invasive fungal infection (IFI) after liver transplant (LT) is associated with significant morbidity and mortality. The optimal antifungal prophylaxis regimen has

not been defined. This study assessed the efficacy of a tiered-approach antifungal prophylaxis regimen in a randomly selected sample of liver transplant recipients (LTR) within 100 days of transplant.

Methods: This retrospective study examined incidence and type of IFIs, susceptibilities, rejection, and mortality in LTRs between 6/1/14-1/31/20. Our institution uses risk factors (RF) (Table 1) to determine the antifungal agent used for prophylaxis. If 1-2 RF are present, pts receive fluconazole 200-400 mg daily based on renal function; if >2 RF are present, pts receive caspofungin 70 mg load, then 50 mg daily. Prophylaxis is initiated post-LT until improvement in clinical status and/or upon transfer out of the ICU.

Table 1: Risk Factors for Invasive Fungal Infection

- Prior liver transplant
- Acute hepatic failure
- Perioperative renal insufficiency (SCr ≥ 2 mg/dL and/or renal replacement therapy (RRT) within 48 hours prior to liver transplant)
- Candida colonization
- Choledochojejunostomy or choledochoduodenostomy anastomosis
- Return to OR within 48 hours
- Chemotherapy within 3 months of transplant
- Transfusion of > 40 units of blood intra-operatively
- OR time > 10 hours

Results: Demographics are illustrated in Table 2. No significant differences were seen in demographic data between those with and without IFIs including MELD score and CMV risk status. 63% of LTR received IFI prophylaxis with a mean duration of 5.7 days of fluconazole and 8.5 days of caspofungin. There were 8 IFI identified despite protocol adherence in these patients (Table 3). There was no significant difference in rates of rejection in LTR with IFI compared to no IFI. No deaths occurred in the 100 days post-transplant. Mortality in the 6 months post-LT was higher in LTR who developed IFIs compared to those who did not (12.5% vs 0%, p=0.001). Pts with IFI were more likely to have had RRT within 48 hours pre-LT and/or within 7 days post-LT (75% vs. 33.7%, p=0.026).

Table 2: Patient Characteristics

Characteristics	*LTRs with IFI (n = 8)*	*LTRs without IFI (n = 92)*
Age at time of transplant (years) – average ± SD	59.9 ± 6.8	53.8 ± 13.4
Male sex – n (%)	5 (62.5)	63 (68.5)
White race – n (%)	7 (87.5)	83 (90.2)
Length of ICU stay – average ± SD	6.4 ± 7.3	5.2 ± 6.9
Received fluconazole prophylaxis – n (%)	5 (62.5)	44 (47.8)
Received caspofungin prophylaxis – n (%)	1 (12.5)	4 (4.3)
Received no IFI prophylaxis – n (%)	2 (25)	35 (38.0)
Received both caspofungin and fluconazole prophylaxis – n (%)	0 (0)	9 (9.8)
Living donor transplant – n (%)	0 (0)	13 (14.1)
Prior liver transplant – n (%)	0 (0)	0 (0)
Acute hepatic failure prior to transplant – n (%)	0 (0)	14 (15.2)
SCr ≥ 2 in 48 hours prior to transplant – n (%)	2 (25)	23 (25)
RRT prior to transplant – n (%)	3 (37.5)	16 (17.4)
RRT and/or SCr ≥ 2 in 48 hours prior to transplant – n (%)	4 (50)	30 (32.6)
RRT post-transplant – n (%)	5 (62.5)	30 (32.6)
Candida colonization – n (%)	0 (0)	4 (4.3)
Choledochojejunostomy or choledochoduodenostomy anastomosis – n (%)	1 (12.5)	13 (14.1)
Return to the OR within 48 hours – n (%)	0 (0)	1 (1.1)
Intra-operative blood products > 40 units – n (%)	1 (12.5)	24 (26.1)
OR time > 10 hours – n (%)	1 (12.5)	10 (10.9)
High Risk for CMV – n (%)	0 (0)	16 (17.4)
Average MELD ± SD	29.8 ± 9.2	29.3 ± 9.0
MELD ≥ 30 – n (%)	3 (37.5)	43 (46.7)

Table 3: Invasive Fungal Infections within 100 Days of Transplant

IFI	*IFI Prophylaxis Agent*	*Number of Risk Factors*	*IFI Susceptibility to Fluconazole*
Aspergillus fumigatus sinusitis	None	0	N/A
Aspergillus fumigatus pneumonia	Caspofungin	4	N/A
Candida albicans hepatic abscess infection	Fluconazole	1	Unknown
Candida glabrata peritonitis	None	0	Susceptible Dose Dependent (SDD)
Candida albicans pneumonia	Fluconazole	1	Unknown
Candida glabrata hepatic abscess and intra-abdominal infection	Fluconazole	1	SDD
Candida glabrata urinary tract infection	Fluconazole	1	Unknown
Candida glabrata and *candida krusei* esophageal candidiasis	Fluconazole	1	*Candida glabrata* – SDD *Candida krusei* - resistant

Conclusions: Our incidence of IFI (8%) in LTR was comparable to the incidence in the reported literature of 4-7%, thus illustrating effectiveness of the antifungal prophylaxis protocol at our center. Given the higher rates of IFI in LTR who received RRT in the 48 hours pre-LT and/or 7 days post-LT, modifying the current protocol to include post-operative RRT as an additional risk factor for IFI should be considered. More studies with larger sample sizes are needed to identify the optimal IFI prophylaxis regimen.

Abstract# 732

Outcomes in High Risk CMV Liver Transplants with Elevated MELD Scores

S. Freedman[1], K. Saunders[2], T. Sparkes[1], B. Masters[1], M. Plazak[1], K. Saharia[3], D. Maluf[3], B. Ravichandran[2], *[1]University of Maryland Medical Center, Baltimore, MD, [2]University of Maryland School of Pharmacy, Baltimore, MD, [3]University of Maryland School of Medicine, Baltimore, MD*

Purpose: There is inconclusive evidence on the impact of MELD score on CMV viremia after liver transplantation. Following the implementation of Share 35, liver transplant allocation to patients with MELD ≥35 significantly improved. This study assessed whether the risk of CMV viremia was increased in a high MELD (≥35) cohort.

Methods: This single center, retrospective, cohort study included liver transplant recipients from 2009 to 2019 who were at high risk for CMV (D+/R-). Patients were grouped by pre-transplant MELD score of <35 (low MELD) and ≥35 (high MELD). Patients received 3 months of CMV prophylaxis with valganciclovir. The primary endpoint was quantifiable CMV viremia by 12 months after transplant. Secondary endpoints were CMV tissue invasive disease, CMV resistance, BPAR, thrombocytopenia, leukopenia, and death. The Cox proportional hazards model was used to identify independent risk factors for CMV viremia.

Results: A total of 244 patients were included. Differences in baseline characteristics (Table 1) were not predictive of CMV viremia, except for alcoholic cirrhosis (HR, 1.76; 95% CI, 1.09-2.85; p=0.02). More patients in the high MELD group developed CMV viremia (37% vs 26%); however, this was not statistically significant (HR, 1.6; 95% CI, 0.99-2.62; p=0.054). Following completion of valganciclovir prophylaxis, the mean time to CMV viremia was 162 ± 61 and 139 ± 62 in the low and high MELD groups, respectively (Figure 1). High rates of leukopenia and thrombocytopenia persisted through 6 months post-transplant (Table 2). Additionally, BPAR occurred early post-transplant in both the low and high MELD groups (median 31 days (13-62) vs 18 days (11-66); p=0.48) and was associated with an increased risk of CMV viremia (HR, 1.94; 95% CI, 1.2-3.15; p=0.007).

Table 1. Baseline Characteristics	Low MELD (n=163)	High MELD (n=81)	p-value
MELD score, median (IQR)	25 (21-29)	39 (37-40)	< 0.001
Age (years), mean ± SD	56 ± 10	49 ± 13	< 0.001
Male, n (%)	126 (77)	48 (59)	0.005
Race, n (%)			0.50
White	138 (85)	67 (83)	
Black	23 (14)	11 (14)	
Other	2 (1.2)	3 (3.7)	
Deceased donor, n (%)	149 (91)	81 (100)	0.006
Transplant indication, n (%)			< 0.001
Alcohol	48 (29)	41 (51)	
HCC	42 (26)	0 (0)	
HBV/HCV hepatitis	20 (12)	6 (7)	
Fulminant	0 (0)	9 (11)	
NASH	27 (17)	7 (9)	
Other	26 (16)	18 (22)	
Induction, n (%)			0.14
Methylprednisolone	147 (90)	67 (83)	
Basiliximab	16 (10)	14 (17)	

Table 2. Clinical Outcomes	Low MELD (n=163)	High MELD (n=81)	p-value
12-month CMV viremia, n (%)	43 (26)	30 (37)	0.12
CMV tissue disease, n (%)	15 (9)	9 (11)	0.65
CMV resistance, n (%)	1 (1)	1 (1)	1.00
Leukopenia (WBC <4x10^3/μL), n (%)			
Month 3	68/144 (47)	35/76 (46)	0.98
Month 6	56/135 (41)	28/70 (40)	0.96
Thrombocytopenia (PLT <150x10^3/μL), n (%)			
Month 3	74/144 (51)	24/76 (32)	0.008
Month 6	76/134 (57)	34/70 (49)	0.34
BPAR, n (%)	45 (28)	21 (26)	0.90
Mortality, n (%)	11 (7)	10 (12)	0.15

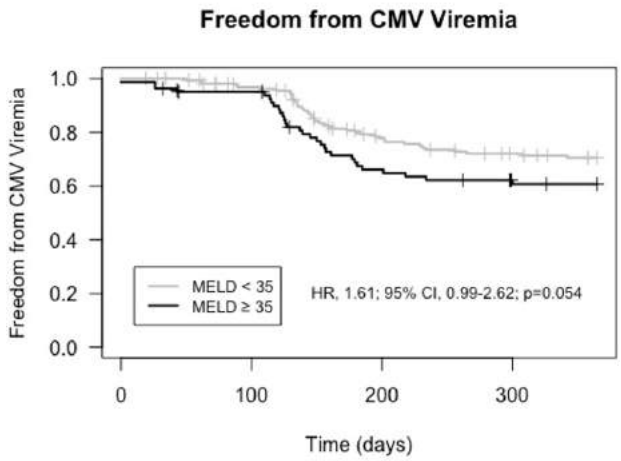

Figure 1. Time to CMV viremia by 12 months post-transplant

Conclusions: Regardless of MELD score, 3 months of CMV prophylaxis results in high rates of CMV viremia, especially after BPAR episodes. Given persistent leukopenia and thrombocytopenia, improved surveillance strategies with routine monitoring of CMV may be preferred over extending the prophylaxis duration in this population.

Abstract# 733

Covid Studies in 208 Patients with Consent for Donation

A. L. Friedman, C. Ezzell, K. Delli Carpini, *LiveOnNY, New York, NY*

Purpose: To prevent transmission of SARS CoV 2 via solid organ donation from deceased donors.

Methods: Comprehensive medical and psychosocial evaluation of potential deceased organ donors included a risk assessment for active infection w2ith SARS CoV 2 which was considered an absolute contraindication. Patients lacking active infection for whom authorization for donation was present, underwent testing for detectable SARS CoV 2 in specimens from the nasopharynx (PCR), bronchoalveolar lavage (PCR) and blood (antibody).

Results: From 3/16/2020 - 12/2/2020 a total of 828 specimens were collected from 208 patients. Nearly all samples were negative for SARS CoV 2. 7 patients were confirmed to have antibody to SARS CoV 2; 6 became donors and 1 was ruled out. Nasopharyngeal specimens were PCR positive in 7 patients, 6 pf them were ruled out. The 7th patient was remotely infected and also was antibody positive; this patient did become a donor.No reports of donor transmission of SARS CoV 2 have been mreport3ed to us.

Conclusions: Active evolution of the evaluation of SARS CoV 2 in deceased organ donor candidates has taken place during the initial phase of the pandemic. Systematic testing of nasopharyngeal, bronchoalveolar lavage and antibody status whenever feasible, facilitated donation by most authorized donors. This strategy has resulted in multiple organ transplants without evidence of SARS CoV -2 transmission.

Abstract# 734

Impact of Valganciclovir Prophylaxis Dosing in High Risk Cytomegalovirus Kidney and Pancreas Transplant Recipients with Delayed Graft Function

A. Gharabagi[1], J. Geyston[1], A. Agarwal[2], S. Rao[3], A. Doyle[3], J. Dann[1], *[1]Pharmacy, University of Virginia Health System, Charlottesville, VA, [2]Transplant Surgery, University of Virginia Health System, Charlottesville, VA, [3]Transplant Nephrology, University of Virginia Health System, Charlottesville, VA*

Purpose: We sought to compare outcomes of cytomegalovirus (CMV) prophylaxis in high risk CMV (donor +/recipient -) kidney and pancreas transplant recipients who received different valganciclovir (VGC) renal dosing strategies and experienced delayed graft function (DGF) or had immediate graft function (IGF).

Methods: This retrospective, single-center cohort review screened all high risk CMV kidney and kidney-pancreas (SPK) transplants from January 1, 2015 through May 1, 2020. Patients were excluded if they did not receive induction with rabbit anti-thymocyte globulin (rATG), required dialysis post-transplant solely for hyperkalemia, or received a prior non-kidney solid organ transplant. Patients received induction with rATG (1.5 - 6 mg/kg), standard triple maintenance immunosuppression, and CMV prophylaxis with VGC. 6-month follow up was completed and 1-year outcomes reported as able.

Results: Baseline characteristics were well-balanced between cohorts with exception to age. No significant differences in rejection or graft loss were observed between transplant recipients with or without DGF. However, resistant CMV, CMV viremia, and death occurred at a higher rate in the DGF cohort. No significant differences were seen among patients with DGF on differing VGC regimens.

Table 1. Baseline Characteristics

Characteristic	DGF (N = 37)	IGF (N = 78)	P-value

Abstract# 735

Clinical Signs Predictive of Covid-19 Mortality Among Transplant Recipients

D. Ginzberg[1], K. Pierce[2], E. Kreiger-Benson[2], M. Graves[2], H. Neumann[3], N. Ali[3], C. Gidea[3], J. Park[3], S. Mehta[3], *[1]Hackensack University Medical Center, Hackensack, NJ, [2]New York University Grossman School of Medicine, New York, NY, [3]New York University Langone Transplant Institute, New York, NY*

Purpose: The presentation of Coronavirus disease 2019 (COVID-19) ranges from mild illness to severe respiratory failure. Disease progression may differ in immunocompromised patients and immunocompetent hosts. Therefore, we aim to characterize COVID-19 clinical presentation and outcomes in solid organ transplant recipients (SOTRs) to identify initial clinical factors that may predict COVID-19 associated mortality.

Methods: We prospectively reviewed baseline demographic and clinical characteristics among adult kidney, pancreas, liver, heart and lung transplant recipients diagnosed with COVID-19 between March 1, 2020 and May 5, 2020 at our transplant center in New York City. A series of chi-square and Fisher's exact tests

were conducted to investigate the relationship between several predictor variables (baseline characteristics, symptoms at presentation, and baseline immunosuppression regimen) and 30-day mortality.

Results: 73 SOTRs (53 kidney, 8 liver, 7 heart, 3 lung, 2 heart/kidney) with SARS-CoV-2 PCR-confirmed COVID-19 were included in the final analysis. Median age was 59 years (IQR 54-68) and 34.2% were female. Median time since transplant was 21 months (IQR 13-46.5). All patients were on baseline immunosuppresion as shown in table 1. The majority of patients were diagnosed in the Emergency Department. Most common presenting symptoms were cough (68.5%), gastrointestinal symptoms (54.8%) and dyspnea (45.2%) with median of 5 days from symptom onset to hospitalization. All patients had elevated inflammatory markers at time of diagnosis (median CRP 54 mg/L, median ferritin 704 ng/mL, median procalcitonin 0.11 ng/mL, median D-dimer 311 ng/mL). 84.1% of patients required supplemental oxygen, including intubation in 19.7%. 13 of 63 (21%) hospitalized patients died. Dyspnea on presentation was the only baseline or presenting patient factor found to be predictive of death (p =.004). When stratified by initial chest X-ray findings, dyspnea combined with abnormal chest X-ray predicted mortality (p=.021) while dyspnea with normal chest X-ray did not.

Conclusions: Presenting symptoms of dyspnea and radiographic signs of pneumonia on initial imaging predicted mortality among SOTRs with COVID-19 in our cohort. These findings can inform allocation of limited resources in COVID-19 management, including the triage and timing of COVID-19 directed therapies early in the illness course among different patient populations.

Abstract# 736

Observational Study of the Clinical Characteristics and Short-term Outcomes of Kidney Transplant Recipients Diagnosed with Coronavirus-19 Infection (sars-cov2) Requiring Hospitalization in New Orleans

S. Giusti[1], S. Chazin[2], P. Vaitla[3], K. Atiemo[4], M. Atari[1], A. Paramesh[4], H. Jeon[4], A. Vijay[4], A. Torres[5], M. Killackey[4], R. Thimmisetty[6], J. Garces[6], *[1]Tulane University Section of Nephrology & Hypertension, New Orleans, LA, [2]Tulane University School of Medicine, New Orleans, LA, [3]University of Mississippi Medical Center, Jackson, MS, [4]Tulane Transplant Institute, New Orleans, LA, [5]Ochsner Medical Center, New Orleans, LA, [6]Ochsner Multi-Organ Transplant Institute, New Orleans, LA*

Purpose: Kidney transplant recipients are at increased risk of severe disease and death caused by Coronavirus-19 infection. The role of immunosuppressive medications in the clinical presentation, disease course, and outcomes is not well understood.

Methods: We analyzed kidney transplant recipients diagnosed with Coronarvirus-19 infection during the initial infection surge requiring hospitalization at two large transplant centers in New Orleans, LA, between February 1, 2020, and April 30, 2020. Patient presentation, clinical course, kidney transplant function, and post-discharge details were included in this analysis.

Results: Twenty-three kidney transplant recipients hospitalized with Coronavirus-19 infection were included in the study. The majority of the patients were black (95.7%). Diabetes, hypertension, and obesity were present in at least 50% of the patients. The most common presenting symptom was fever, present in 52.2% of patients. All patients were managed with a reduction in immunosuppression. 60.9% of patients received azithromycin, 47.8% received hydroxychloroquine, 8.7% received remdesivir, and 8.7% received IV methylprednisolone pulse. The average length of stay was approximately 4.5 days (range 2 to 18 days). 73.9% of the patients sustained acute kidney injury, with an average peak serum creatinine of 3.81 mg/dL. 26% of the patients required renal replacement therapy. 77% of patients developed proteinuria (at least +1 proteinuria on urinalysis). 37.5% of patients required mechanical ventilation, and of these, 77.8% died. Overall, 30.4% of patients died of Coronavirus-19 infection-related complications during admission. Of the 16 patients discharged, the average serum creatinine during the first follow-up visit was 2.09 mg/dL compared with an average preadmission serum creatinine of 1.76 mg/dL.

Conclusions: During the initial Coronavirus-19 infection surge in New Orleans, we noted that kidney transplant recipients had initial symptoms similar to the general population. However, we recorded a high incidence of acute kidney injury and the need for renal replacement therapy. Patients who required mechanical ventilation had a high mortality rate. There was an over-representation of black patients.

Abstract# 737

Infection Rates in Heart Transplant Recipients With Combined Tacrolimus and Sirolimus at High versus Low Concentrations

S. Goyal, J. Lyons, J. Negrelli, M. Liebo, A. Heroux, *Loyola University Medical Center, Maywood, IL*

Purpose: Assess the impact of tacrolimus-sirolimus (TAC/SRL) concentration on infection rate in heart transplant recipients (HTR).

Methods: A retrospective review of HTR on TAC/SRL for ≥ 1 year from 01/2006-08/2019 was conducted. Drug concentrations were defined as high (≥ 15 ng/mL) or low (< 15 ng/mL), calculated as the summation of individual medication's annual average concentration for every year of therapy. For patients on TAC/SRL for > 1 year, each year of therapy was considered its own discrete case. The primary outcome was median rate of infection, defined as positive culture or other documented clinical finding treated with a full course of antimicrobial. Secondary outcomes included the incidence of any, bacterial, viral, and fungal infections as well as acute rejection, defined as clinically evident cellular rejection (Grade 0R, 1R, 2R or 3R) treated with high-dose corticosteroids.

Results: A total of 60 individual case years were analyzed from 22 patients. There were 21 vs 39 cases in the high and low TAC/SRL groups, respectively. The average TAC/SRL concentration was 18.5 ± 2.5 ng/mL in the high and 13.0 ± 1.3 ng/mL in the low group. Median infection rates were significantly greater in the high vs low TAC/SRL group (2 vs 0, p<0.0001). The incidence of any infection, bacterial infections and acute rejection were significantly greater in the high vs low group (Table 1). There were no cases of antibody mediated rejection in either group.

Table 1. Outcome results between case years with high and low TAC/SRL concentrations

	High TAC/ SRL (n=21)	Low TAC/ SRL (n=39)	P-value
Rate of infection, median (IQR)*	2 (1-2)	0 (0-1)	**P<0.0001**
Any infection incidence, n (%)	18 (86)	17 (44)	**0.002**
Bacterial infection incidence, n (%)	18 (86)	15 (38)	**P<0.0001**
Viral infection incidence, n (%)	5 (24)	4 (10)	0.164
Fungal infection incidence, n (%)	1 (5)	2 (5)	0.984
Acute rejection incidence, n (%)	14 (67)	9 (23)	**0.001**
**Some case years had ≥ 1 recorded infection*			

Conclusions: Higher combined concentrations of TAC/SRL in HTR were associated with increased infections per year. Targeting TAC/SRL concentrations of < 15 ng/mL is reasonable to decrease the risk of infection, however the risk of rejection should be considered. Given the retrospective nature of the study, it is unknown if target concentrations were increased before or after a rejection episode was experienced. Prospective studies are warranted to confirm findings and to further assess the association of combined TAC/SRL concentrations on allograft rejection.

Abstract# 738

An Evaluation of Pjp Prophylaxis and Anemia Among Renal Transplant Recipients

J. Hedvat, N. Poladi, D. Salerno, G. Dube, N. Lange, *NewYork-Presbyterian Hospital, New York, NY*

Purpose: Dapone and atovaquone are therapeutic options for PJP prophylaxis in renal transplant recipients. The objective of this study was to evaluate the incidence of anemia in renal transplant recipients receiving these agents.

Methods: This was an IRB-approved, single-center retrospective analysis of adult renal transplant recipients who received either dapsone or atovaquone for PJP prophylaxis between July 2012 and August 2019. The primary endpoint was the change in hemoglobin within 90 days of drug initiation. Other endpoints of interest included incidence and management of anemia at multiple time points post-transplant. Categorical variables were compared with Pearson's chi-squared or Fischer's exact test and continuous data were compared utilizing Wilcoxon rank-sum test. Statistical analyses were performed using Stata 14.2.

Results: 100 patients were included in the final cohort; 50 patients in each the dapsone and atovaquone groups. In the dapsone and atovaquone groups, the median age was 52 and 50.5 years, 44% and 42% were Caucasian, and median time to treatment initiation was 27 and 39 days post-transplant, respectively. All patients receiving dapsone had normal G6PD function. There was no difference in baseline hemoglobin between groups (9.7 g/dL versus 9.8 g/dL, p=0.83). The median nadir hemoglobin values were 8.6 g/dL and 9.6 g/dL in the dapsone and atovaquone groups, respectively (p=0.047). The median decrease in hemoglobin from baseline to nadir was 1.3 g/dL in dapsone patients and 0.2 g/dL in atovaquone patients (p=0.001). Dapsone was discontinued in 46% of patients, whereas atovaquone was discontinued in 18% (p=0.001).

Conclusions: Among renal transplant recipients with normal G6PD activity, dapsone is associated with greater hemoglobin reductions and rates of drug discontinuation as compared to atovaquone.

Abstract# 739

Covid-19 in a Kidney Transplant Patient Associated with Collapsing Glomerulopathy

W. Hninn, M. Merzkani, H. Murad, A. Malone, A. Java, G. Rajashekar, R. Delos Santos, T. Alhamad, *Washington University School of Medicine, St. Louis, MO*

Purpose: Coronavirus- 19 is a novel virus with various clinical presentations ranging from a cold to severe acute respiratory syndrome. However, little is known about it's association with glomerulonephritis. We present a case of COVID-19 in a kidney transplant recipient who developed collapsing Focal segmental glomerulosclerosis (FSGS).

Methods: A 49-year-old African American female who had end stage kidney disease secondary to lupus nephritis received a deceased donor kidney transplant. Post-transplant course was complicated with delayed graft function for 12 days. At 4 months after her transplant, she presented to the hospital with malaise, nausea, vomiting, diarrhea and fever of 101 F. Initially treated empirically for urinary tract infection due to pyuria and lack of respiratory symptoms. However because of a persistent fever, Covid-19 PCR test was performed that resulted positive.

Results: Chest X ray showed right middle and right lower lobe opacities. She was treated in March 2020 with hydroxychloroquine and we held her mycophenolic acid while continuing tacrolimus and prednisone. Patient was subsequently found to have new onset nephrotic range proteinuria without nephrotic syndrome as well as an AKI with creatinine going to 2. Labs showed negative donor specific antibodies as well as negative DsDNA and normal complement C3 and C4 levels. Urinalysis showed hematuria and proteinuria. Kidney allograft biopsy showed collapsing glomerulopathy with severe podocyte foot process effacement affecting approximately 90-100% of the capillary loop surface area. There was no evidence of cellular or antibody-mediated rejection and c4d was negative. She was treated with plasma exchange and rituximab. Patient was maintained with plasmapheresis every week. Creatinine slowly improved and proteinuria gradually decreased to subnephrotic range as shown in Figure 1.

Conclusions: COVID-19 infection may result in a wide range of kidney injuries including collapsing FSGS. COVID-19 may serve as an immunologic trigger for FSGS. The mechanism can be similar to other viral infections such as parvovirus B19, HIV and cytomegalovirus. Large number of cases are needed to examine the best treatment option.

Abstract# 740

Breakthrough Cytomegalovirus DNAemia in High vs Intermediate Risk Heart Transplant Recipients

G. Huang[1], O. E. Beaird[1], M. Davis[2], M. Carlson[1], S. Chang[1], P. Gaynor[1], A. Fan[2], M. Deng[3], A. Multani[1], A. Nsair[3], J. Schaenman[1], *[1]Infectious Diseases, UCLA, Los Angeles, CA, [2]Pharmacy, UCLA, Los Angeles, CA, [3]Cardiology, UCLA, Los Angeles, CA*

Purpose: Cytomegalovirus (CMV) is one of the most common infections after transplantation and continues to cause significant morbidity and mortality despite prophylaxis and screening strategies. Guidelines recommend 3-6 months of post-transplant prophylaxis with 900mg daily of valganciclovir (VGC) in intermediate (R+) and high risk (D+/R-) heart transplant recipients. At our institution, R+ patients receive 450mg daily of VGC for 6 months and for high risk (D+/R-) patients 900 mg daily for 12 months. In this study we aim to determine rates of CMV DNAemia among these 2 groups and to examine if the 450 mg dose is effective at preventing CMV DNAemia.

Methods: Retrospective chart review of adult patients (>= 18 yo) undergoing heart transplantation at a single center from January 2017-December 2019.

Results: One-hundred and thirty-nine patients received a heart transplant between January 2017 and December 2019. Of those, 16 were identified as "low risk" (CMV D-/R-) and excluded. Of the 123 remaining patients, 83 were male and the median age at time of transplantation was 56. Thirty-six patients (29.3%) of patients experienced CMV DNAemia within 1 year of transplantation and 17 (13.8%) had a CMV DNA above the detectable threshold. Age, induction with anti-thymocyte globulin, rejection at 1 year, and mortality at 1 year did not differ between the groups. CMV DNAemia above the quantifiable threshold along with discharge on the equivalent of 900mg daily of VGC was significantly higher in the high-risk group (Table). In the high-risk group, 6 (21.4%) were discharged on lower doses of VGC due to renal dysfunction. Of the patients with breakthrough CMV DNAemia, 4 of 9 patients were on prophylaxis at the time in the high-risk group (44.4%) and 2 of 8 patients in the intermediate group (25%).

Conclusions: Despite having a larger proportion of patients on 900mg daily of valganciclovir, the high-risk patients developed a higher incidence of CMV DNAemia at 1 year compared to the intermediate risk population. The rate of CMV DNAemia in the intermediate risk group was low. Whether adherence to the 900 mg daily dose can decrease rates of DNAemia is currently under investigation in a larger patient cohort.

	High risk (n = 28)	Intermediate risk (n = 95)	p-value
Male	20 (71.4%)	63 (66.3%)	0.61
Age (IQR)	55 (34-71)	56 (41-63)	0.96
Anti-thymocyte globulin Induction	6 (21.4%)	17 (17.8%)	0.67
Discharged with 900mg valganciclovir prophylaxis during transplant hospitalization	9 (32.1%)	8 (8.4%)	0.01
DNAemia at 1 year	9 (32.1%)	8 (8.4%)	<0.01
CMV DNA level, IU/mL	856 (304.25-2231.5)	436 (231.5-1632.5)	0.403
Rejection at 1 year	4 (14.3%)	11 (11.5%)	0.53
Death at 1 year	2 (7.1%)	8 (8.4%)	1

Table 1. Comparison of high vs intermediate risk heart transplant recipients.

Abstract# 741

Relationship Between Tacrolimus Blood Levels and Covid-19 Pandemic in Kidney Transplant Recipients

T. Inoue[1], K. Unagami,[2], A. Ishiwatari[3], T. Kanzawa[3], T. Shimizu[3], K. Omoto[3], M. Inui[3], T. Suzuki[1], H. Ishida[4], K. Tanabe[3], *[1]Department of Nephrology, Kameda Medical Center, Chiba Kamogawa, Japan, [2]Department of Organ Transplant Medicine, Tokyo Women's Medical University, Tokyo, Japan, [3]Department of Urology, Tokyo Women's Medical University, Tokyo, Japan, [4]Department of Organ transplant medicine, Tokyo Women's Medical University, Tokyo, Japan*

Purpose: The novel coronavirus 2019 infection (COVID-19) caused a pandemic, prompting Tokyo, Japan, to restrict on the free movement of people in March 2020. Kidney transplant recipients are at high risk for critical COVID-19 due to chronic immunosuppression and coexisting conditions. For the follow-up of kidney transplant recipients during this pandemic, the number of hospital visits or use remote counseling should be reduced to minimize the risk of infection. However, the management of kidney transplant recipients during the COVID-19 pandemic is uncertain.

Methods: This single-center retrospective observational study included 980 patients who, more than a year previously, had undergone kidney transplantation and were taking extended-release tacrolimus once a day, with a target trough level of 4 to 6 ng/ml. We evaluated the effects of coronavirus pandemic on clinical outcomes such as tacrolimus blood level, renal function, and rejection in kidney transplant recipients, comparing pandemic data with non-pandemic data obtained between September 2019 and August 2020 in our hospital.

Results: Comparing pandemic data with non-pandemic data, the mean interval between hospital visits was 5.5±2.6 vs. 7.3±4.5 weeks (P=2.68×10-14). Serum Cr levels and rejection rates after kidney transplant showed no significant differences between both groups. There were no significantly differences in the coefficient of variation (CV) in tacrolimus blood levels, the rate of changes in oral medication, and the rate of deviation from the target trough level during the pandemic.

Conclusions: In kidney transplant recipients, blood levels of tacrolimus were maintained at target trough levels during the COVID-19 pandemic.

Abstract# 742

Clinical Course and Outcomes in Solid Organ Transplant Recipients with Covid-19

R. C. Jackson[1], S. Challa[2], A. Halim[1], N. Kelly[3], D. Maluf[4], K. Shetty[3], Z. Lominadze[3], *[1]Department of Medicine, University of Maryland School of Medicine, Baltimore, MD, [2]Internal Medicine, University of Maryland Medical Center Midtown, Baltimore, MD, [3]Program in Transplantation, Department of Medicine, University of Maryland Medical System, Baltimore, MD, [4]Program in Transplantation, University of Maryland Medical System, Baltimore, MD*

Purpose: We characterized the outcomes of COVID-19 in our population of solid organ transplant recipients (SOTRs). Since these individuals are immunocompromised, with multiple comorbidities, we hypothesized that they would be at increased risk of COVID-19 related complications and manifest delayed viral clearance.

Methods: A single-center retrospective chart review was conducted of all COVID-19 positive SOTRs in our hospital system from March to November 2020. Variables of interest included demographic data, clinical course, virologic assays, clinical suspicion for graft dysfunction, and biopsy results. Re-admissions within 60 days of discharge were recorded, as were persisting positive SARS-CoV2 PCR tests >4 weeks from initial diagnosis.

Results: We identified 60 SOTRs who tested positive for COVID-19 by nasopharyngeal swab PCR. This included 40 renal, 17 liver, and 9 heart, lung, pancreas, or small bowel transplant recipients ("other"). 7 patients had received dual organs. 66.6% were men and 63% African American. The most common comorbidities were hypertension (88%), chronic kidney disease as defined by an abnormal Cr (68%), diabetes (50%), and obesity defined by BMI >30 (33%). Forty patients required hospitalization, with a median 6.5-day length of stay. 15 were admitted to an ICU, including 8 who required mechanical ventilation and 3 who required oxygen via high flow nasal cannula. Other outcomes are summarized in the Table. The readmission rate was high, and a 9.3% mortality rate was found in non-liver transplant recipients. In general, immunosuppression management consisted of antimetabolite and calcineurin inhibitor dose reduction. However, graft rejection was not proven on biopsy, despite being suspected in 3 cases (2 kidney, 1 liver).

Conclusions: COVID-19 in SOTRs results in higher rates of hospitalization, ICU admission, and death, as compared to reported outcomes in the general population. Our series showed clinical variability depending on type of organ transplant, with worse outcomes in non-liver transplant recipients. As we move toward the approval and distribution of effective vaccines, it is important to recognize that SOTRs represent a group that is particularly vulnerable to this virus, and would benefit from early access to preventive strategies.

Demographics and COVID-19 outcomes in SOTRs by organ transplant type

	Kidney	Liver	Other
Sample size (N)	40	17	9
Average age (years)	53.6	57.2	55.2
Sex (% male)	75	52.9	66.7
Median LOS (days)	6	9.5	6
Readmissions (%)	22.5	11.8	66.7
Persistent + PCR (%)	15	29.4	0
Deaths (%)	10	0	11.1

Abstract# 743

Immune Response to Covid-19 in Kidney Transplant Waitlist Patients

P. T. Jindra[1], C. M. Foye[1], I. Sharf[2], A. Rana[1], T. N. Galvan[1], A. Awan[1], C. A. O'Mahony[1], B. V. Murthy[1], *[1]Baylor College of Medicine, Houston, TX, [2]Baylor St. Luke's Medical Center, Houston, TX*

Purpose: The purpose of this study was to determine the effect of SARS-CoV-2 infection on the immune response in Kidney Transplant Waitlist Candidates (KTWC) and its clinical impact on their ability to get transplanted.

Methods: Initial kidney transplant work-ups were performed including high resolution HLA typing, Flow PRA and single antigen bead assessment of anti-HLA antibody specificities pre-COVID-19 pandemic. Our study group contained 12 KTWC with known positive COVID tests ranging in age from 29-71 years, predominantly Hispanic (75%) and all were male gender. Serum samples were tested pre COVID-19 pandemic and at the time of a positive COVID-19 test using the Luminex based LABScreen COVID Plus assay (One Lambda). IgM and IgG immune responses to SARS-CoV-2 were assessed for a panel of spike, RBD and nucleocapsid determinants as well as other common coronaviruses.

Results: KTWC who tested positive for SARS-CoV-2 by RT-PCR (92%) developed robust IgG responses to all five SARS-CoV-2 antigens expressed in the bead panel. Furthermore, 66% additionally produced IgM responses to SARS-CoV-2 antigens with predominance towards spike proteins and only 17% positive for nucleocapsid protein. 33% of KTWC lost their IgM antibody positivity to SARS-CoV-2 antigens while maintaining significantly strong IgG reactivity suggesting patients were in various phases of SARS-CoV-2 infection. Within other coronaviruses tested KTWC produced strong responses to the spike proteins from common human coronaviruses 229E, NL63, OC43 and HKU1. Surprisingly, 67% of KTWC also had significant IgG immunity to the SARS-CoV Spike S1 protein. Pre-pandemic sera did not show any antibody responses to SARS-CoV-2 proteins however, immunity to common coronaviruses remained high. We did not observe a change in KTWC PRA levels or subsequent rise in anti-HLA antibodies in post SARS CoV-2 infection. There was no association between HLA antigens and degree of either IgM or IgG responses to SARS-CoV-2 or common coronaviruses.

Conclusions: During the COVID-19 pandemic it is critical to have the tools to accurately detect immunity to the SARS-CoV-2 virus. The unintended consequences of SARS-CoV-2 infection in patients awaiting transplant needed to be explored. KTWP were able to mount an effective immune response to 5 distinct protein domains on SARS-CoV-2. Patients with active infection produced both IgM and IgG antibodies against SARS-CoV-2. Despite mounting a stong immune response to SARS-CoV-2 no additional HLA sensitization was observed. Tracking how long these IgG antibodies to SARS-CoV-2 domains persist in patient sera will continue to inform us in how long a patient might remain protected and the effectiveness of a SARS-CoV-2 vaccine once administered.

Abstract# 744

Probiotic Protocol to Reduce Perioperative Infection After Liver Transplantation

M. Jorgenson[1], Q. Yang[2], D. Yang[2], G. Leverson[2], C. Saddler[2], J. Smith[2], N. Safdar[2], L. Fernandez[2], D. Al-Adra[2], *[1]UW Health, Madison, WI, [2]UW School of Medicine and Public Health, Madison, WI*

Purpose: Evaluate efficacy and safety of a probiotic preparation to reduce perioperative infection in patients undergoing liver transplant surgery

Methods: Adult patients receiving liver transplantation from 5/7/2019- 9/30/2019 received a probiotic preparation of lactobacillus + guar gum prebiotic fibers given perioperatively for 14 days (POD 0- POD 14). These patients were compared to a standard of care (SOC) cohort who received liver transplant in the year prior to implementation of the protocol (3/1/2018-3/1/2019). In a power analysis using the 7% and 35% infectious incidence from prior literature, at least 33 subjects per group were needed to have at least 80% power for finding a significant difference in 30-day infection rates using a test of proportions. All patients received perioperative surgical prophylaxis and standard transplant infection prophylaxis per institutional protocol. Primary objective was incidence of perioperative bacterial infection. Secondary objectives were safety/toxicity as measured by lactobacillus-associated infectious events and one year rates of rejection, graft and patient survival

Results: 144 patients met inclusion criteria; 33 in the probiotic cohort, 111 in the SOC cohort. Clinical characteristics were similar in the two groups (Table 1). Patients who received the probiotic preparation had a similar incidence of perioperative infective events (probiotic 13.4% vs SOC 14.5%, p=0.82). There were no lactobacillus-associated infectious events in the probiotic cohort (probiotic 0% vs SOC 1.8%, p>0.99). Rates of rejection, graft and patient survival were not different between groups (Table 2).

Conclusions: An early interim analysis of the probiotic protocol suggests safety based on lack of lactobacillus-associated infections in the probiotic group. While rates of bacterial infection were not different, it is possible our sample size was not adequate to detect a more modest difference in infection rates. Ongoing evaluation of the benefits of perioperative probiotics in the current era of liver transplantation is warranted.

Abstract# 745

Analyzing the Impact of Covid-19 in the Hospitalized Cohort of Liver Transplant Recipients: An Early Systematic Review and Meta-Analysis

J. Kumar[1], I. Reccia[2], P. Bachul[1], D. DiSabato,[1], R. Barth[1], J. Fung[1], T. Baker[1], P. Witkowski[1], *[1]University of Chicago, Chicago, IL, [2]Imperial College, London, United Kingdom*

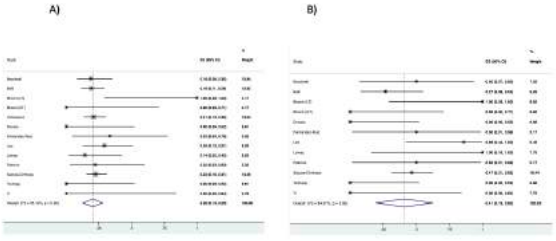
Purpose: To determine pooled prevalence of outcomes among hospitalized liver transplant recipients with COVID-19 through meta-analysis.
Methods: A database search was completed between Dec1, 2019-Nov15, 2020, as PRISMA guidelines and random-effect analysis performed. Twelve studies, 517 hospitalized liver transplant patients with COVID-19 were included.
Results: Common presenting symptoms were fever(71%), cough(62%), dyspnea(48%), and gastrointestinal symptoms(28%). 77%(95%CI, 61%-93%) transplant were due to cirrhosis. The most prevalent co-morbidities were hypertension(55%), diabetes(45%) and cardiac disease(21%)(Table-1,2). In-hospital mortality was 20%(95%CI, 13%-28%); which arose significantly in ICU group 41% (95%CI, 19%-63%)(P value<0.00)(Fig1:A,B). Further, analysis showed significantly increased mortality-risk in elderly(OR=4.26)(95%CI, 13%-28%) but no significant effect in terms of gender or time since transplant(Fig1:C-E).
Conclusions: We observed a higher prevalence of dyspnea, gastrointestinal symptoms than general population. In-hospital mortality was congruent with non-transplant population with multiple co-morbidities but appeared to be less than decompensated cirrhotic patients(26-40%) as reported in literature. Further, higher mortality risk observed in elderly could be attributed to age-associated co-morbidities.

Table 1: Summary statistics outlined as pooled estimate of outcomes of interests

Attributes	Events	Total	Studies	Pooled prevalence (95%)
Age (yrs)	NA	502	9	63.58 (59.66 - 67.48)
Diabetes	211	486	8	0.45 (0.38 - 0.53)
Hypertension	251	486	8	0.55 (0.47 - 0.64)
Cardiac disease	88	472	7	0.21 (0.13 - 0.30)
Lung disease	42	352	6	0.14 (0.06 - 0.22)
ARDS	81	146	5	0.56 (0.26 - 0.86)
ITU admissions	95	417	12	0.22 (0.12 - 0.32)

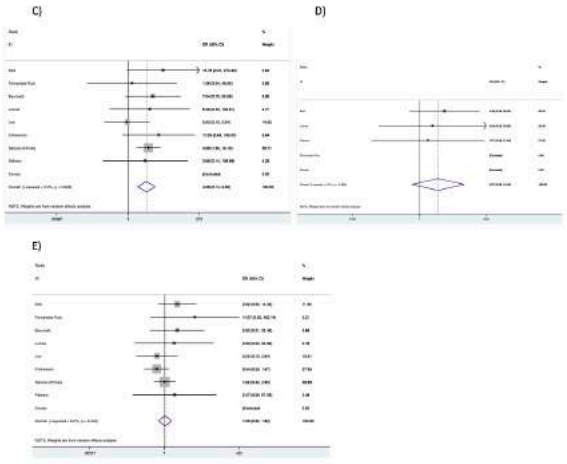
Table 2: Summary statistics outlined as pooled estimate of outcomes of interests

Attributes	Events	Total	Studies	Pooled prevalence (95%)
Fever	240	350	8	0.71 (0.61-0.81)
Cough	213	342	7	0.62 (0.53-0.72)
Dyspnea	144	353	9	0.48 (0.36-0.61)
Gastrointestinal symptoms	87	293	6	0.28 (0.20-0.35)
CNI withheld/ reduced	39	91	4	0.38 (0.09-0.67)
MMF withheld/ reduced	28	55	5	0.60 (0.17-0.90)
Increase/pulse steroid	59	283	7	0.22 (0.13-0.31)



1.A) Hospital mortality was 20% with ES of 0.20 (95%CI 0.13 - 0.28). (ES = Effect Size)

1.B) Intensive care mortality was 41% with ES of 0.41 (95%CI 0.19 - 0.63).



1.C) Figure shows significantly higher risk in ≥60/65 years group (red dotted line) with OR of 4.26 (95% CI 2.14-8.49).

1.D) Figure shows that both post-transplant period (>2 years) and (≤2 years) are comparable (red dotted line) with OR of 3.07 (95% CI 0.65-14.46).

1.E) Figure shows that both genders are comparable (red dotted line) with OR of 1.05 (95% CI 0.62-1.80).

Abstract# 746

COVID-19 in Kidney Transplant Recipients in the Southeastern United States: A Single Center Experience

K. R. Kumm, S. H. Shawar, R. C. Forbes, B. P. Concepcion, *Vanderbilt University Medical Center, Nashville, TN*

Purpose: The novel coronavirus, severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) or COVID-19, has emerged as a viral pandemic and brought unprecedented challenges worldwide on health care systems, including our transplantation community. Data on the clinical characteristics and outcomes of patients with COVID-19 infection in kidney transplant recipients (KTRs) remain uncertain. Here we describe the clinical characteristics and outcomes of KTRs in the Southeastern US who contracted COVID-19.

Methods: A retrospective review of KTRs who tested positive for COVID-19 from March 15th, 2020 until November 25th, 2020 and followed at our institution were included. Data including patient demographics, history, laboratory results, radiological findings, and clinical outcomes was collected from the electronic medical record. Summary statistics using Kruskal-Wallis and Chi-square tests were performed. Multivariable logistic regression was used to identify risk factors for inpatient admission.

Results: There were 104 patients who tested positive for COVID-19 either at our institution or a referring hospital (Table 1). Fifty-six (54%) patients required hospitalization. Labs on admission were: mean WBC 6.6±2.8 (x10^3/mcL), serum creatinine 2.3±1.7 (mg/dL), CRP 96±84 (mg/L), ferritin 1093±1052 (ng/mL), procalcitonin 0.62±1.0 (ng/mL), lactate 1.2±0.4 (mEq/L). Admitted patients were treated with dexamethasone (54%) and remdesivir (23%), and the anti-metabolite was held in 71%. Nineteen patients required ICU stay, 13 were intubated, 25 developed AKI and 12 died related to COVID-19 (11%). Mean length of inpatient stay was 11±13 days. After adjustment for age, DM and CAD status, the risk of admission due to COVID-19 was higher in those presenting with fever (OR 3.12, 95% CI 1.23-7.92, P-Value 0.017), and SOB (OR 7.64,95% CI 1.89-30.9, P-Value 0.004) (Table 2).

Conclusions: The majority of KTRs with COVID-19 in our cohort required hospital admission. The mortality rate was 11% which is at the lower end of the spectrum of what has been previously reported. Despite this, COVID-19 remains a significant risk for our kidney transplant recipients with a high rate of hospital admission.

Abstract# 747

The Gut Microbiota Diversity and Metabolite Production is Reduced in Liver Transplant Recipients and Associated with Post-Operative Infection

C. J. Lehmann, R. Keskey, R. Nayak, E. Littmann, E. Pamer, T. Baker, *University of Chicago, Chicago, IL*

Purpose: Liver transplant (LT) recipients have abnormal microbiota before and after transplantation. (1,2) The association between fecal microbiota, metabolites, and clinical outcomes in liver transplantation are not well established. We correlated the microbiota composition and metabolite production in fecal samples with early post-operative outcomes, including infection.

Methods: In a prospective observational study, we collected fecal samples and determined microbiota composition by 16S ribosomal RNA sequencing in LT recipients. Fecal short chain fatty acid (SCFA), primary, and secondary bile acid concentrations were determined by targeted metabolomic analyses. Inverse Simpson index was used to compare diversity between enrolled subjects and healthy controls. These data were compared to length of stay following transplantation, MELD-Na score at the time of transplant, and post-operative infection. The organisms causing clinical infection were compared to the microbiota of the subjects.

Results: 13 LT patients were enrolled, and 40 stool samples were collected in the peri-transplant period. In addition to LT, 3 patients received a kidney transplant, 1 patient received a heart transplant, 1 patient is listed for a heart, liver, and kidney transplant. Compared to healthy controls, the microbiota of LT recipients had reduced diversity ($p<0.001$). [Fig1] The health promoting taxa *Bacteroidetes*, *Ruminococcaceae*, and *Lachnospiraceae*, and microbiota derived SCFAs were markedly diminished.

Conclusions: The microbiota and metabolome of LT recipients are markedly abnormal and appear to be associated with clinically relevant and microbiologically predictable post-operative infection. Patient recruitment, sample collection, analysis, correlation with outcomes and potential interventional studies are ongoing.

Abstract# 748

COVID-19 in Hospitalized Kidney Transplant Recipients: Clinical Course, Prognostic Factors and Differences Between First and Second Waves

N. Macías, M. Rodríguez Ferrero, A. Acosta, J. Carbayo, Á. González Rojas, A. Muñoz de Morales, A. García Prieto, M. Goicoechea, *Nephrology, Hospital Gregorio Marañón, Madrid, Spain*

Purpose: The aim was to describe the clinical course and management of SARS-CoV-2 infection in kidney transplant recipients (KTR) hospitalized with COVID-19, identify risk factors for severity, and analyze the differences between first (March-June) and second (Aug-Nov,2020) waves.
Methods: Retrospective, single-center study in 48 KTR (24 in each wave) admitted with COVID-19. Baseline features, immunosuppression, clinical findings, laboratory and radiological data and therapies were analyzed to identify risk factors for "severe COVID" (requiring oxygen reservoir bag, high-flow nasal cannula and/or invasive mechanical ventilation).
Results: Age was 58.9 ± 13 years, 75% were male, 60.5 (24 - 143) months after KT. 20.8% were nosocomial and there were 2 "reinfections". Main symptoms were fever (71%), dyspnea (56%), cough (48%) and diarrhea (40%). 87.5% developed pneumonia, 77% needed supplemental oxygen, 14.6% were admitted to ICU (12.5% for invasive ventilation) and 8.3% died.
Table 1 shows main differences in KTR with severe COVID. In multivariable regression analysis with different models including age, sex, blood group, comorbidity, immunosuppression, RAS blockers and:1) SatO2, platelets and LDH at admission: only everolimus (adjusted OR: 204, p 0.047) as independent predictor for severity.2) clinical course: everolimus (adjusted OR: 61.7, p 0.021) and poor clinical course at one week (adjusted OR: 546, p 0.015) were associated with severe COVID.In the second wave the patients consulted earlier (p 0.029) and SARS-CoV-2 infection was less severe (p 0.001) with less use of reservoir (p 0.008), lower inflammatory markers at admission [CRP (p 0.010), IL-6 (p 0.048) and ferritin (p 0.045)], and more mild cases without oxygen need (p 0.048). There were fewer pneumonia at admission and 48h after, but no differences at one-week, and more patients were treated with steroids (79% vs 42%, p 0.017).
Conclusions: Everolimus could represent a risk factor for severity in KTR hospitalized with COVID-19. In the second wave there was a wider use of steroids, though SARS-CoV-2 infection was less severe.

Abstract# 749

Weathering the Cytokine Storm: Therapeutic Plasma Exchange for the Management of Severe Covid19 in Solid Organ Transplant Recipients

A. Mattiazzi[1], J. Pagan[1], L. A. Mendez Castaner[2], A. Fernandez[1], R. Zamora Gonzalez[1], J. Simkins[1], L. Preczewski[1], Y. Natori[1], S. Anjan[1], G. Guerra[1], *[1]Miami Transplant Institute, Miami, FL, [2]Miami Trasnplant Institute, Miami, FL*

Purpose: The treatment of SARS-CoV-2 associated pneumonia in solid organ transplant recipients (SOTr) continues to be under investigation. Timely control of the cytokine release storm (CRS) in its early stage is of essence to improving treatment of adult respiratory distress syndrome (ARDS). We report here the results of the use of therapeutic plasma exchange (TPE) as adjunct therapy for the management of SOTr.

Methods: Single-center, retrospective cohort study of SOTr diagnosed with SARS-CoV-2 infection from March 1st to September 30th, 2020. All patients received severity stratified institutional protocolized treatment and TPE was started based on clinical and inflammatory parameters of CRS and ARDS. CRP, Ferritin, D-Dimer IL-6, IL10, TNF-A, IFN-G and TGF-A were measured pre and after completion of the treatment.

Results: Of the 129 COVID-19 positive SOTr during the study period, 27 (21%) developed ARDS requiring the use of TPE. Baseline characteristics are shown in Table 1. The median time from transplant to infection was 287 (12-3593) days and the mean ICU stay was 13.5 (8-57) days. All patients had ARDS and reduction of baseline Immunosuppression. The management and results are shown in Table 2. The mean dose of TPE was 5 (3-20) sessions. Our data showed a down trend in measured cytokines achieved at the end of the TPE treatment. The mean ± SD pre and post TPE CRP level were 15.95 ± 9.4 and 2.30 ± 5.80. The post treatment CRP correlated with improvement in oxygen requirements with HR of death of 1.35. Patient and graft survival were 62.9 and 96.3% respectively.

Conclusions: The supportive use of TPE in severe SARS-CoV-2 associated CRS and ARDS appears to improve oxygen requirements and prognosis. More research is warranted to confirmed our findings.

Abstract# 750

Sars-cov-2 versus Non-sars-cov-2 Infection Among Solid Organ Transplant Recipients: Case Control Study

M. A. Mendoza[1], M. Raja[1], S. Anjan[1], S. C. Curel[2], G. Rosello[3], A. Fernandez[1], A. Chandorkar[4], C. O'Brien[5], A. Phancao[5], N. Sinha[1], R. Vianna[1], M. Loebe[1], C. Gaetano[1], J. Simkins[1], M. Morris[1], L. Abbo[1], J. Camargo[1], G. Guerra[1], Y. Natori[1], *[1]Department of Medicine, University of Miami, Miami, FL, [2]Miller School of Medicine, University of Miami, Miami, FL, [3]University of Miami, Miami, FL, [4]University of Minnesota, Minneapolis, MN, [5]Miami Transplant Institute, University of Miami, Miami, FL*

Purpose: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) pandemic has been raging since the end of 2019. The clinical differences between non-SARS-CoV-2 coronavirus and SARS-CoV-2 in solid organ transplant recipients (SOTR) are not well defined.

Methods: This is a case control study of adult SOTR with PCR positive nasopharyngeal sample or bronchoalveolar lavage, for either SARS-CoV-2 or non-SARS-CoV-2 coronavirus, from 1/2017 to 10/2020. Follow up period was up to three months. Secondary infections were diagnosed by culture or viral PCR from a sterile specimen. Clinical outcomes were compared amongst both groups.

Results: Seventy-two non-SARS-CoV-2 coronavirus and 129 SARS-CoV-2 infections were identified. Patient's demographic information and outcomes are shown in table 1 and 2 respectively. Secondary infections and ICU admissions were statistically

significantly different between both groups, and higher mortality was observed in the SARS-CoV-2 group. With time to event analysis, there was trend to higher mortality with SARS-CoV-2 infection as compared to non- SARS-CoV-2 (p=0.06)(figure).
Conclusions: Our study shows SOTR with SARS-CoV-2 infection may have a significant worse outcome as compared to non-SARS-CoV-2. Secondary infection was also common after this respiratory viral infection in both groups.

Table 1. Patient's characteristics and laboratory findings

Data in median, IQR	SARS-CoV-2 (129)	non-SARS-CoV-2 (72)	p-value
Gender (female)	54	33	0.59
Age	53 (45-62)	60.5 (42.3-66)	0.17
Time to infection post- SOT (months)	27.7 (8.2-74.3)	15 (7.3-40.2)	0.11
Kidney transplant	91	27	
Liver transplant	16	8	
Neutrophil to Lymphocyte ratio	1.7 (1.8-6.7)	5.6 (2.8-13.4)	0.08

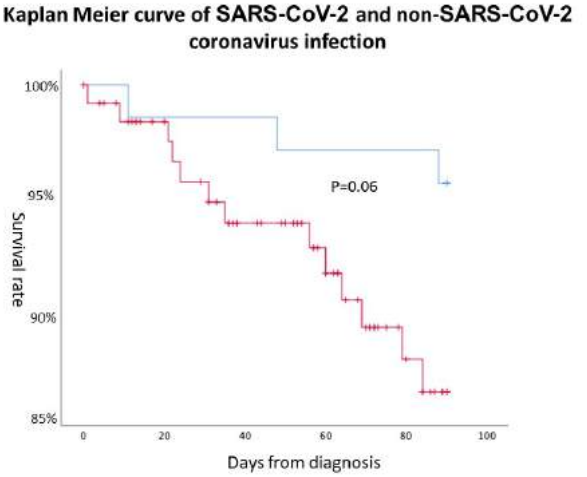

Table 2. Outcomes

	SARS-CoV-2 (129)	non-SARS-CoV-2 (72)	p-value
Lower respiratory tract infection	115 (89.1%)	38 (52.8%)	0.10
Secondary infection	50 (38.8%)	17 (23.6%)	0.028
Intensive care unit admission	34 (26.3%)	9 (12.5%)	0.04
Rejection	12 (9.3%)	4 (5.6%)	0.35

Abstract# 751

Multi-drug Resistant Infections in Solid Organ Transplant Recipients, a New Era of Risk

L. A. Morais, D. Reynoso, A. Lea, M. Mujtaba, S. Merwat, R. Kulkarni, J. Fair, M. Kueht, *University of Texas Medical Branch, Galveston, TX*
Purpose: Antibiotic drug resistant organisms (DRO) [extended spectrum beta-lactamase (ESBL), vancomycin-resistant enterococcus (VRE), and carbapenem resistant bacteria (CRB)] are becoming more prevalent and pose a significant healthcare burden. As immunocompromised transplant patients are particularly susceptible to nosocomial infection, we sought to examine hospital-wide patterns of DRO in abdominal organ transplant recipients.
Methods: All cultures from index- and re-admissions for abdominal organ transplant recipients at our institution from 2016 to 2019 were included in a retrospective analysis. The presence of DRO were analyzed to ascertain correlation among: patient age, organ, hospital site where the culture was drawn, length of stay (LOS), days since transplant, and infection rate.
Results: A total of 571 culture isolates were obtained from 181 solid organ recipients during the study period, including 49 drug resistant bacterial isolates from 31 patients. Over the study period, DROs as a percentage of total cultures increased (R^2=0.49, p<0.05). DROs were collected from non-ICU- (63%) nearly twice as frequently as from ICU-sites (33%). 59% of DRO cultures were obtained greater than 90 days after transplant. 1- and 3-yr survivals were similar for those that did and did not experience a DRO infection (DRO vs non-DRO: 1-yr, 90 vs 96%; 3-yr, 87 vs 91%, p=0.77). 30-day readmissions were more common in patients that developed a DRO (35 vs 58%, p<0.05).
Conclusions: The incidence of DROs has been increasing and, although rare, now includes carbapenem resistance. Contrary to expected, DRO infections were detected more often in the non-ICU setting and often greater than 90 days post transplant. These data suggest that antibiotic stewardship is paramount and require hospital-wide vigilance.

Abstract# 752

Seroprevalence of SARS-CoV-2 Antibodies in Transplant Recipients in a Croatian Transplant Center

A. Mrzljak[1], Z. Jurekovic[1], J. Pavicic Saric[2], L. Antolasic[3], L. Milasincic[3], I. Tabain[3], T. Vilibic Cavlek[3], *[1]Department of Internal Medicine, Merkur University Hospital, Zagreb, Croatia, [2]Department of Anesthesiology, Merkur University Hospital, Zagreb, Croatia, [3]Department of Microbiology, Croatian Institute of Public Health, Zagreb, Croatia*
Purpose: In Croatia, the first case of coronavirus disease (COVID-19) has been reported on 25 February 2020; however, the COVID-19 seroprevalence in the liver (LTR) and kidney transplant recipients (KTR) is presently unknown.
Methods: From 9 September to 13 November 2020, at the beginning of the second wave COVID-19 epidemic curve in Croatia, we performed a systematic screening for COVID-19 in outpatient solid organ transplant recipients (n=495).

Serum samples were tested for the presence of SARS-CoV-2 IgG antibodies. Serological tests were performed by a commercial enzyme-linked immunosorbent assay (ELISA) using spike glycoprotein (S) and nucleocapsid protein (N) antigens (Vircell, Granada, Spain).
Results: LTR (n=265) were older than KTR (n=230) (59.8±10.7 vs 51.8±12.1 years, p<0.01). Out of 495 transplant recipients, 97 (19.6%) were positive for anti-SARS-CoV-2-IgG. There was no difference in the seroprevalence between LTR and KTR, 20.4% vs. 18.7%, respectively, p>0.05. Anti-SARS-CoV-2-IgG were found in both symptomatic and asymptomatic patients. However, seropositive patients reported a significantly higher incidence of fever (25.3% vs. 12.8%, p=0.011) and anosmia (5.2% vs 0.9% p=0.023). Out of 97 anti-SARS-CoV-2-IgG positives, only 22% reported previous nasal-throat swabs RT-PCR testing, with 28.6% of them being SARS-CoV-2 RNA positive.
Conclusions: In Croatia, the SARS-CoV-2 seroprevalence in LTR and KTR is 19.6% with seropositivity documented in both symptomatic and asymptomatic patients. The presence of specific symptoms increases the likelihood of SARS-CoV-2 seropositivity. The COVID-19 screening program should be increased in Croatia.

Abstract# 753

Current Practices for Management and Treatment of COVID-19 in Immunocompromised Adults: A Survey of Institutions

H. H. Nam[1], S. Aslam[2], O. Beaird[3], G. Forrest[4], M. Fung[5], A. Limaye[6], A. Multani[3], J. Nelson[7], R. Rakita[6], L. Strasfeld[8], J. Schaenman[3], *[1]Medicine, University of California - Irvine, Orange, CA, [2]Division of Infectious Diseases and Global Public Health, University of California - San Diego, San Diego, CA, [3]Medicine, University of California - Los Angeles, Los Angeles, CA, [4]Medicine, Rush University, Chicago, IL, [5]Medicine, University of California - San Francisco, San Francisco, CA, [6]Medicine, University of Washington, Seattle, WA, [7]Medicine, Stanford University, Palo Alto, CA, [8]Medicine, Oregon Health and Science University, Portland, OR*
Purpose: The optimal testing strategy for solid organ transplantation (SOT) donor and recipient evaluation, as well as treatment for COVID-19 is unknown. We assessed the management strategy of COVID-19 within the West Coast Transplant Infectious Disease group.
Methods: A survey assessing strategies for COVID-19 management was sent to 11 Transplant Infectious Diseases providers from 8 centers.
Results: For both living and deceased donor clearance, 81.8% (n=9) providers utilize one negative PCR within 72 hours of transplantation. However, when a living donor tests positive for SARS-COV-2, 36.4% (n=4) will require two negative PCR tests >24 hours apart for donor clearance, with 90.9% (n=10) requiring at least a 28-day wait period prior to retesting. Amongst providers caring for lung transplant recipients, 77.7% (7/9) utilized negative PCR from donor BAL as part of pre-transplant evaluation. For transplant candidates, all providers required both the absence of COVID-19 symptoms with only one negative PCR test. In candidates that tested positive for SARS-COV-2, 54.5% (n=6) required at least two negative PCRs prior to transplantation. For positive candidates, 63.6% (n=7) considered re-testing for PCR negativity at 20 days. When a transplant recipient tested positive for SARS-CoV-2, all providers would reduce antimetabolites and utilized dexamethasone for patients requiring oxygen therapy. Remdesivir was prescribed by all providers with variability in the timing of administration.
Conclusions: Management and treatment of COVID-19 for SOT donors, candidates, and recipients was heterogeneous. While all providers require at least one negative COVID-19 test as both donor and recipient evaluation prior to transplantation, the number of negative tests sent varied amongst providers, geographical region, and clinical scenario. The significant diversity of COVID-19 management strategies for immunocompromised adults seen in this study highlights the further need for studies defining the optimal management of COVID-19.

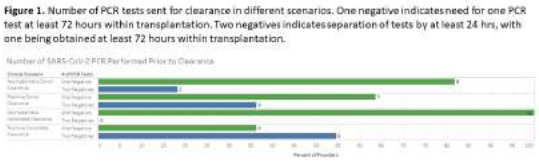

Figure 1. Number of PCR tests sent for clearance in different scenarios. One negative indicates need for one PCR test at least 72 hours within transplantation. Two negatives indicates separation of tests by at least 24 hrs, with one being obtained at least 72 hours within transplantation.

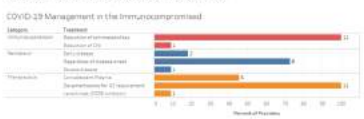

Figure 2. Therapeutic options and management

Abstract# 754

Evaluation of High-versus Low-Dose Valganciclovir for Cytomegalovirus Prevention in Adult Liver Transplant Recipients: A Single Center Experience

P. Parikh[1], M. Siddiqui[2], O. De La Cruz[2], G. Gupta[2], D. Kumar[2], I. Yakubu[2], *[1]Our Lady of the Lake Regional Medical Center, Baton Rouge, LA, [2]Virginia Commonwealth University Health System, Richmond, VA*
Purpose: Cytomegalovirus (CMV) is the most common infection after solid organ transplantation and is associated with increased morbidity and mortality. CMV prophylaxis is widely considered as standard of care after liver transplantation, and valganciclovir (VGCV) 900 mg daily (adjusted for renal function) is currently the preferred regimen. While effective in preventing CMV infection, this dosing strategy is associated with profound leukopenia, which poses a barrier to optimal immunosuppression management post-transplant and consequently increases risk of rejection. Literature in kidney transplantation has demonstrated that a lower dose of VGCV 450 mg daily (adjusted for renal function) is equally effective in preventing CMV disease and causes less leukopenia. There is a paucity of literature on the use of such reduced dose strategy in liver transplantation. The purpose of this study is to evaluate the safety and efficacy of high-versus low-dose valganciclovir in adult liver transplant recipients.
Methods: This is a single-center retrospective chart review study of high (D+/R-) and intermediate (R+) risk adult liver transplant recipients who received low-dose valganciclovir (VGCV) 450 mg daily (adjusted for renal function) at our center. Patients were compared to a historical cohort of liver transplant recipients who received high-dose VGCV 900 mg daily (adjusted for renal function). The primary outcome was the incidence of CMV infection or disease within 12 months post-transplantation. Safety outcomes include the incidence of leukopenia at specific time intervals up to 12 months and the need for granulocyte colony stimulating factor (GCSF) at any point while on VGCV therapy.
Results: Baseline patient demographics and transplant characteristics were found to be comparable across both groups. CMV infection occurred in 13.8% (n=8) and 9% (n=3) in the high-dose and low-dose groups respectively (p=0.302). In the high-dose VGCV group, 75% (6/8) of patients that developed CMV infections were CMV D+/R- and infections mostly occurred after completion of prophylaxis. In the low-dose group, 33% (1/3) of patients were CMV high risk. Patients receiving high-dose VGCV experienced more leukopenia at 1 month post-transplant, than those in the low dose group (5.8 K/uL vs 7.5 K/uL; p = 0.0114). The use of GCSF while on VGCV therapy was also higher in the high- versus low-dose group (7 patients vs 1 patient). There was no difference in acute rejection, resistant CMV infections, biopsy confirmed tissue invasive disease, breakthrough CMV or VGCV duration of therapy. Patient and graft survival outcomes were also similar between groups.
Conclusions: Low-dose valganciclovir is associated with similar outcomes to high-dose valganciclovir when used for CMV disease prophylaxis in liver transplant recipients. There was a higher use of G-CSF in patients on high-dose valganciclovir.

Abstract# 755

Beta-lactam Allergies Among Solid Organ Transplant Recipients: Prevalence and Association with Transplant Admission Length of Stay

N. N. Pettit[1], V. Nguyen[2], C. T. Nguyen[1], A. Lew[1], J. Pisano[1], L. M. Potter[1], *[1]University of Chicago Medicine, Chicago, IL, [2]University of Michigan College of Pharmacy, Ann Arbor, MI*

Purpose: Previous studies have identified that 14-27% of solid organ transplant (SOT) recipients report a beta lactam allergy (BLA). Patients with BLAs often receive less effective and more toxic antibiotics, and often have worse clinical outcomes such as prolonged length of hospital stay. This is of particular concern for patients undergoing SOT given their high risk for developing post-transplant infections, including those caused by multi-drug resistant pathogens, given their frequent exposure to the healthcare setting and antibiotics. We sought to identify the prevalence of BLA among SOT recipients at our medical center and evaluate the impact of BLAs on transplant admission length of stay (LOS).

Methods: All patients undergoing SOT from 1/1/2017 to 12/31/18 were included in this retrospective review. Baseline characteristics include age, gender, race/ethnicity, and type of transplant. Allergy data included allergen, reaction, and date documented. LOS was calculated based on admit and discharge dates for the transplant admission.

Results: During the time period, 54 (16.4%) patients had a documented BLA out of a total of 329 patients undergoing a SOT. Table 1 summarizes the baseline characteristics. The prevalence of BLA was 23% in lung (12 of 52), 19% in liver (11 of 58), 15% in kidney (19 of 130), 15% in heart (10 of 65), 17% in pancreas/islet (1 of 6), and 6% in multiorgan recipients (1 of 18). The most common type of reaction was rash (26%), followed by hives/urticaria (22%). Table 2 provides a summary of the reactions documented. The mean LOS among patients with a BLA vs. without was 26.7 days and 33.4 days, respectively.

Conclusions: Similar to previous studies, we observed an overall prevalence of BLAs among SOT recipients of 16.4%. We did not observe a prolonged transplant admission LOS among those with a BLA vs. without. Further evaluation to assess the impact of BLA labels among SOT recipients on additional outcomes such as antibiotic prescribing, post-transplant readmissions, rates of multi-drug resistant and Clostridioides difficile infections, and mortality is needed.

Table 1: Baseline Characteristics

	BLA (N=54)	Without BLA (N=275)
Age, mean ± st dev	56 ± 15	51 ± 15
Gender, M (%)	31 (57)	180 (65)
Race/Ethnicity

Abstract# 756

Covid vs Non Covid Pneumonia in Kidney Transplant Recipients

R. Prashar, N. Khoury, P. Shrivastava, S. Yeddula, T. Kitajima, E. Ulrich, M. Ramesh, A. Patel, S. Nagai, M. Samaniego-Picota, *Henry Ford Hospital, Detroit, MI*

Purpose: Compare clinical characteristics and outcomes in kidney transplant recipients (KTRs) hospitalized with COVID vs Non COVID Pneumonia.

Methods: This is a retrospective case-control study examining epidemiologic, laboratory and clinical characteristics of KTRs hospitalized with COVID vs Non COVID pneumonia. Cases were determined by consecutive KTRs diagnosed with COVID-19 from March 20, 2020 through April 25, 2020. Data were censored on April 30th, 2020. 39 patients had COVID, 11 were excluded because they did not have pneumonia. All patients with pneumonia were hospitalized. Controls were determined by searching the EMR for hospital admissions by diagnosis codes for pneumonia and kidney transplant status from January 1,2019 to October 30, 2019. 49 patients were identified, out of which 22 were excluded due to misclassification of pneumonia, dual organ transplantation and failed kidney transplant. Primary end point was progression to respiratory failure requiring mechanical ventilation, ICU admission or in-hospital all-cause mortality. Secondary end points were ARDS, shock and AKI requiring RRT.

Results: Demographics, comorbidities and laboratory findings in 28 KTRs with COVID and 27 KTRs with Non COVID pneumonia are shown in

Characteristics	Non COVID patients	COVID patients	*P* value
Demographics			
Age (median [IQR])	63.00 [48.00, 68.50]	62.00 [53.75, 67.50]	0.98
Female sex - no. (%)	10 (37.0)	11 (39.3)	0.86
Black race - no. (%)	17 (63.0)	24 (85.7)	0.06
BMI (median [IQR])	26.70 [23.75, 32.80]	28.30 [25.95, 33.28]	0.32
Coexisting conditions - no. (%)			
Atrial Fibrillation	4 (14.8)	8 (28.6)	0.33
Peripheral Vascular Disease	7 (25.9)	6 (21.4)	0.07
Coronary artery disease	7 (25.9)	6 (22.2)	1
Diabetes	14 (51.9)	19 (67.9)	0.28
Hypertension	27 (100.0)	27 (96.4)	1
Laboratory Findings -no. (%)			
Anemia	23 (85.2)	19 (67.9)	0.20
Leukopenia	0 (0.0)	7 (25.0)	0.01
Leukocytosis	8 (29.6)	5 (17.9)	0.35
Lymphopenia	17 (63.0)	26 (92.9)	0.01
Imaging of lungs -no. (%)			
Unilateral infiltrates	17 (63.0)	9 (32.1)	0.03
Bilateral Infiltrates	10 (37.0)	19 (67.0)	
QSofa -no. (%)			
0	14(51.9)	9(32.1)	0.28
1	9(33.3)	15(53.6)	
2	4(14.8)	4(14.3)	

Patients with COVID pneumonia were more likely to be leukopenic, lymphopenic and present with bilateral infiltrates. KTRs with COVID were more likely to be black. (trend towards significance p=0.058).

Outcomes are summarized in

	Non COVID	COVID	Odds ratio (95% CI)	*P* value
Death – no. (%)	2 (7.4)	10 (35.7)	6.94(1.35,35.60)	0.02
ICU admission – no. (%)	5 (18.5)	14 (50.0)	4.4(1.29,14.92)	0.02
Mechanical ventilation – no. (%)	3 (11.1)	10 (35.7)	4.44(1.07,18.52)	0.05
ARDS – no. (%)	1 (3.7)	13 (46.4)	22.53(2.67,189.78)	<0.001
Shock – no. (%)	2 (7.4)	9 (32.1)	5.92(1.14,30.65)	0.04
Acute kidney injury requiring RRT – no. (%)	1 (3)	6 (21)	7.09(0.79,63.47)	0.10

KTRs with COVID pneumonia had higher odds of death (OR=6.94), ICU admission (OR=4.44), developing ARDS(OR=22.53) and shock(OR=5.92) as compared to KTRs with Non-COVID pneumonia.

Conclusions: KTRs with COVID 19 pneumonia present with more leukopenia, lymphopenia , bilateral infiltrates , and tend to have higher mortality , ICU admission, ARDS and shock as compared to non COVID pneumonia. These results help us have a higher index of suspicion for COVID-19 pneumonia in KTRs who present with leukopenia, lymphopenia and bilateral infiltrates, in the setting of negative RT-PCR (95% sensitivity)or in KTRs in whom results are still awaited, so that timely treatment can be provided.

Abstract# 757

PDSA Model to Improve Pneumococcal Vaccine Adherence Among Kidney Transplant Candidates

J. M. Ramakrishna, L. Brumble, C. R. Libertin, *Division of Infectious Diseases, Mayo Clinic, Florida, Jacksonville, FL*

Purpose: Streptococcus pneumoniae infections occur in solid organ transplant patients at a rate of 146 per 100,000 persons per year versus 11.5 per 100,000 persons per year in general population. Despite CDC and AST recommendations, studies report suboptimal pneumococcal immunzation in the KT candidates. Our objective was to develop a quality improvement (QI) intervention at Mayo Clinic Florida's (MCF) Transplant Center to increase the number of KT candidates screened for prior pneumococcal immunizations and improve vaccine adherence.

Methods: A QI process to improve pneumococcal vaccine adherence in KT candidates at MCF was implemented using Plan-Do-Study-Act (PDSA) methodology. After IRB approval was obtained, data was obtained by retrospective electronic health record review and interventions were designed and implemented over six-week periods based on observed quality gaps. Baseline cohort consisted of patients evaluated for KT at MCF's transplant center from December 2, 2019-January 14, 2020 baseline. Interventions for PDSA cycle 1 (February 11, 2020-March 25, 2020) and PDSA cycle 2 (August 11, 2020 - September 22, 2020) included sharing baseline data findings enterprise wide, distributing education materials to all ID MCF transplant center staff, and providing ID MCF advanced care practitioners and physicians with a standard pneumococcal vaccine question set to include in their consultation note. Outcomes included documentation rates of prior pneumococcal vaccinations, pneumococcal vaccine order frequency, and Prevnar 13 order completion rate. Data were analyzed using simple descriptive statistics and Pearson's chi-square.

Results: Study subjects totaled 214 (baseline n=61, PDSA 1 n=103, PDSA 2 n=50). Pneumococcal immunization history documentation rates improved from baseline 96.7% to 100% post-PDSA cycle 2 ($p<0.001$). Percentages of patients with a history of Prevnar 13 in baseline, PDSA 1 and PDSA 2 cohorts were 32.8%, 23.3%, and 12.0%, respectively ($p<0.001$). Percentages of patients with a history of Pneumovax 23 in baseline, PDSA 1 and PDSA 2 cohorts were 32.8%, 34.0%, and 46.0%, respectively ($p=0.001$). Prevnar 13 and Pneumovax 23 were ordered in the baseline cohort of 92.7% and 100% of patients, respectively. These order rates dropped to 88.6% for Prevnar 13 and 96.8% for Pneumovax 23 post-PDSA likely due to care providers factoring in logistical implications of COVID-19 ($p<0.001$). Prevnar 13 order completion documentation rates were 41.5%, 38.0%, and 43.6% in baseline, PDSA 1 and PDSA 2 cohorts, respectively ($p<0.001$).

Conclusions: The data reflect that improving pneumococcal vaccine adherence in KT candidates is not a simple process and QI requires ongoing effort by all team members. While pneumococcal vaccines were usually ordered by care providers when appropriate, follow-up with patients who chose to complete their vaccines at a site other than MCF remains a gap in care practices.

Abstract# 758

Covid-19 in Hiv-infected Solid Organ Transplant Recipients: A Case Series

M. Ramanathan, A. Fernandez, Y. Natori, J. Simkins, J. Camargo, M. Morris, N. Rivera, M. Loebe, G. Ciancio, L. Abbo, A. Mattiazzi, G. Guerra, S. Anjan, *University of Miami, Miami, FL*

Purpose: Coronavirus disease 2019 (COVID-19) is associated with increased mortality and morbidity in immunosuppressed patients. Data on management and outcomes in HIV-infected solid organ transplant (SOT) recipients is lacking.

Methods: Single center, retrospective case series of HIV-infected SOT recipients who were diagnosed with COVID-19 by nasopharyngeal reverse transcriptase-polymerase chain reaction (RT-PCR) between April to November 2020. All patients had anti-retroviral therapy (ART) induced HIV viral load suppression at diagnosis.

Results: Six consecutive patients were identified (**Table.1**). Four patients required hospitalization; 2 were managed outpatient. Four were symptomatic with fever (75%), cough (50%), dyspnea (50%) and diarrhea (25%). An increase in inflammatory markers was seen in all patients, however only 4 (66%) required supplemental oxygen. Median time of follow up was 75 (range, 14-205) days. On diagnosis, first mycophenolate mofetil was discontinued or dose decreased by half. Calcineurin inhibitors and prednisone were continued. In addition, investigational therapies hydroxychloroquine, tocilizumab, remdesivir, dexamethasone were used in 3 (50%), 1 (17%), 1 (17%), 1 (17%), respectively (**Table 2**). All patients were on protease inhibitor sparing ART. A decrease in CD4 count from baseline was seen at the time of diagnosis which recovered over time. Overall, 5 (83%) survived, 1 (17%) died, 1 (17%) kidney transplant recipient had biopsy-proven acute T-cell mediated rejection 9 days after diagnosis with subsequent graft loss. Secondary infections were diagnosed with positive blood or respiratory cultures in 3 (50%). Death reported was due to septic shock from a secondary infection. Three patients had a negative SARS-CoV-2 RT-PCR at a median of 25 (range, 20-56) days from diagnosis.

Conclusions: We report good outcomes in this unique, high risk cohort of HIV-infected SOT recipients. Balancing a decrease in immunosuppression and monitoring graft function to avoid graft loss is extremely important. Further studies are needed to determine the cumulative effect of HIV infection and organ transplant status on the severity of COVID-19.

Abstract# 759

Clinical Outcomes of Culture-Positive Pneumonia in Solid Organ Transplant Recipients

L. Rice[1], A. C. Kalil[2], D. Hixson[2], M. Leick[3], *[1]Monument Health, Rapid City, SD, [2]University of Nebraska Medical Center, Omaha, NE, [3]Nebraska Medicine, Omaha, NE*

Purpose: The purpose of this study is to determine the differences in clinical outcomes of culture-positive pneumonia in solid organ transplant (SOT) recipients compared to non-SOT patients.

Methods: This retrospective cohort study included adult inpatients with positive bronchoalveolar lavage (BAL) or sputum cultures. SOT patients were matched 1:2 to non-SOT patients based on age and gender. The primary outcome was in-hospital mortality. Secondary outcomes included 90-day mortality, time-to-appropriate antibiotics, antibiotic duration, days on ventilator, hospital length of stay (LOS), and hospital readmission.

Results: This study included 73 SOT and 146 matched non-SOT patients. The average age was 54.7 years; 67.6% were male. The majority were Caucasian (87.7% vs 82.2%, p=0.3). Of the SOT patients, the majority were kidney (30.1%) and liver (20.6%) recipients. Average time post-transplant was 6.4±8 years. Regarding baseline characteristics, SOT recipients were more likely to have hypertension (72.6% vs 58.2%, p=0.04), diabetes (43.8% vs 29.5%, p=0.03), and end-stage renal disease (12.3% vs 0.7%, p=0.0001). In-hospital mortality for SOT recipients was not statistically significantly different compared to non-SOT (27.4% vs 18.5%, p=0.13). Hospital LOS was longer for SOT recipients (34.9 vs 25.3 days, p=0.03) and time to readmission was shorter (19.6 vs 26.6 days, p=0.03). Other secondary outcomes were similar between groups. In terms of cultures, SOT recipients were more likely to have BAL cultures (42.5% vs 28.1%, p=0.03). The most common organisms were *Pseudomonas aeruginosa* (31.5% vs 23.3%, p=0.09), Methicillin-sensitive *Staphylococcus aureus* (9.6% vs 22.6%, p=0.045), Methicillin-resistant *S. aureus* (13% vs 13.7%, p=0.68), *Klebsiella pneumonia* (6.8% vs 11%, p=0.45), and *Escherichia coli* (9.6% vs 8.9%, p=0.69). The most common initial and appropriate antibiotics were vancomycin, piperacillin-tazobactam, and cefepime. Combination antibiotics were initiated in most patients (64.4 vs 63.7%, p=0.92). Appropriate antibiotic duration was similar (9.1 vs 13.2 days, p=0.31), but SOT recipients were more likely to not receive appropriate antibiotics (21.9% vs 11.6%, p=0.03).

Conclusions: In-hospital mortality in SOT recipients was not significantly different from that in non-SOT patients. SOT recipients had a significantly longer hospital LOS, shorter time to readmission and were less likely to receive appropriate antibiotics.

Abstract# 760

Donor-Derived Tuberculosis in Lung Transplant Recipients, a Single Center Experience

M. Robbins, D. Kabbani, C. Cervera, C. O'Neil, R. Cooper, K. Halloran, S. Grocholski, K. Doucette, *University of Alberta, Edmonton, AB, Canada*

Purpose: Donor-derived (DD) tuberculosis (TB) in solid-organ transplantation (SOT) is rare with the largest review to date identifying only 25 cases of proven or probable DD-TB.

Methods: We describe the largest case-series of DD-TB to date, including four cases among lung transplant recipients between 2015-2020 with a focus on identifying risk factors for transmission and characterizing clinical presentations.

Results: All affected recipients were Canadian-born non-Indigenous lung transplant recipients with negative tuberculin skin tests (TST) and without epidemiologic risks for TB infection. In terms of donors, 3/4 were foreign-born with the fourth being Canadian-born but with epidemiologic risks for TB including Indigenous status, homelessness and alcohol abuse. One donor had a prior reactive TST (unknown at donation) and one donor had prior imaging demonstrating a small calcified pulmonary granuloma. All cases presented within three months post-transplant (range 7-12 weeks) with fever and dyspnea in all recipients. Imaging revealed nodular opacities and mediastinal lymphadenopathy in all. One recipient was both smear and culture positive, while the other three recipients were smear negative and culture positive. Three presented with isolated pulmonary TB while the fourth was diagnosed with disseminated TB. Treatment in one case included isoniazid (INH), rifabutin (RFB), and pyrazinamide (PYR) induction followed by INH and RFB maintenance for a total of 12 months with clinical cure. The second case was treated with RFB, PYR, and moxifloxacin induction followed by RFB and moxifloxacin maintenance for a total of nine months with clinical cure. The third was treated with INH, RFP, ethambutol, and moxifloxacin induction followed by INH and RFP maintenance for a total of 9 months. The fourth case was initiated on INH, RFB, and moxifloxacin but died within one week of treatment initiation.

Conclusions: In summary, DD-TB remains an uncommon complication following SOT. Our case series confirms donor TST reactivity, presence of lung granulomata, and epidemiologic risks including country of origin, Indigenous status, homelessness, and alcohol abuse are associated with increased risk of DD-TB. This suggests enhanced communication between jurisdictions with respect to prior LTBI testing and chest imaging may improve identification of donors with LTBI. However, some donors may still pose a risk of TB transmission, suggesting a possible role for enhanced screening or pre-emptive LTBI therapy in this group.

Abstract# 761

Pregnancy After CMV Infection Following Uterus Transplantation: A Case Report

M. Rosenzweig, A. Wall, G. Testa, L. Johannesson, *Abdominal Transplant Surgery, Baylor University Medical Center, Dallas, TX*

Purpose: Uterus transplantation (UTx) is a repeatedly proven treatment for women with absolute uterine factor infertility who wish to carry a pregnancy. One aspect of UTx is the potential for transmission of cytomegalovirus (CMV) from the donor to the recipient. CMV infection is not only a frequent complication after solid organ transplantation but also poses a risk to the fetus during pregnancy after UTx. To date, there have been no reported cases of pregnancy following UTx from CMV positive donors into CMV negative recipients.

Methods: Chart review of a case in which a CMV negative UTx recipient received a CMV positive living donor uterine graft and developed active CMV infection prior to embryo transfer.

Results: The UTx recipient was treated with 3 months of prophylactic Valcyte after transplantation and was monitored with CMV serum PCR every week. She developed an asymptomatic CMV infection 5 months post-transplant and was successfully treated with ganciclovir and cleared the virus. Single embryo transfer was performed 8 months post UTx. She did not have recurrence of CMV during pregnancy. She delivered a healthy baby at 37 weeks gestation.

Conclusions: This case shows that CMV positive donors may be used for CMV negative recipients in UTx. However, these patients should be closely monitored for CMV infection during the post-transplant course and subsequent pregnancy.

Abstract# 762

Covid-19 Reinfection in a Kidney Transplant Patient

Z. Saeed Zafar, D. Malhotra, *Nephrology, Yale School of Medicine, New Haven, CT*

Purpose: Several cases have demonstrated positive SARS-CoV-2 PCR testing in patients who were initially shown to have cleared the infection. These reinfections may represent new strains of SARS-CoV-2 that can have significant clinical implications in the transplant population and affect public health initiatives aimed at controlling this pandemic. The purpose of this case is to highlight the presentation of COVID-19 reinfection in a kidney transplant recipient.

Methods: We present a 66-year-old male patient with a history of ESRD due to lithium toxicity, status post deceased donor kidney transplant, maintained on Belatacept, prednisone and mycophenolate mofetil. He was first diagnosed with

COVID-19 in March 2020 after presenting with cough, fever and hypoxia. Chest x-ray revealed bilateral infiltrates. Treatment included atazanavir, hydroxychloroquine and tocilizumab. Mycophenolate was withheld for the duration of his treatment. Despite resolution of all symptoms, nasopharyngeal PCR testing remained positive for SARS-CoV-2 even on discharge. He subsequently cleared his infection and tested negative twice, 3 months apart. He was later found to have AKI and a biopsy showed Banff 2A Acute Cellular Rejection which was treated with steroids and thymoglobulin. He was readmitted in November with fatigue and shortness of breath and tested positive again for SARS-CoV-2 by nasopharyngeal swab PCR. There was no hypoxia and chest x-ray did not show any infiltrates. Prerenal azotemia resolved with IV hydration. Serological studies showed presence of SARS-CoV2 IgG antibodies. Mycophenolate was again held. There was concern that this could be prolonged intermittent shedding from his previous infection. However genetic sequencing from samples of his first and current infection were compared and revealed a different strain consistent with a new infection. He recovered and was discharged.
Results: COVID-19 reinfection in the transplant population is of significant interest as these patients may be susceptible to prolonged recovery. Several points of interest can be derived from this case. Firstly, the clinical significance of different viral strains and its effect on vaccination efforts may provide significant public health information. Second, the utility and importance of SARS-COV2 antibody testing may provide insight into the course of reinfection and degree of protection conferred by antibodies thereby providing guidance about the appropriate management of immunosuppression. Our patient had SARS-CoV-2 antibodies and his mild course allowed us to re-institute his immunosuppression early. Lastly, the potential for reinfection may necessitate continued testing and protective measures beyond vaccination efforts.
Conclusions: To the best of our knowledge this is the first reported case of COVID-19 reinfection in a kidney transplant recipient with a different viral strain confirmed by genetic sequencing.

Abstract# 763

Kidney Transplant Outcomes in HIV+ Recipients: A Single-Center Study

M. Samra[1], A. Hall[2], I. Tang[2], *[1]Medicine, Edward Hines VA, Hines, IL, [2]Medicine, University of Illinois, Chicago, IL*

Purpose: HIV+ patients are eligible to recieve a kidney transplant (KT) provided they meet criteria of undetectable viral load (VL) and CD4 count ≥200. We compare the long term transplant outcomes between HIV+ and HIV-kidney transplant reciepients (KTRs).
Methods: This is a retrospective analysis of HIV+ patients who received a KT from 2005 to 2018 at an urban academic center. Allograft and patient survival between HIV + and HIV - KTRs using Kaplan-Meier survival estimates at one-, three-, and five-year were compared. Secondary outcomes including incidence of biopsy proven acute rejection (BPAR) and BK virus associated nephropathy (BKVAN) and cytomegalovirus (CMV) disease were reviewed.
Results: We identified 21 HIV+ KTRs, 86% African American, 9% Hispanic, and 5% Caucasian. The median age was 47 years (interquartile range [IQR], 36-53),a median BMI of 27 (IQR, 23-33),dialysis vintage median period of 5.5 years (IQR, 1.4-7.6) and 67% were male. Of the 13 living donor KTs, 2 were ABO incompatible and 2 were crossmatch positive. Nine KTRs received an antiretroviral combination including nucleoside/nucleotide reverse transcriptase inhibitors (NRTIs) with a non-nucleoside reverse transcriptase inhibitor, 7 received NRTIs with a protease inhibitor, and 6 received NRTIs with an integrase inhibitor. Five (24%) KTRs were co-infected with HCV. **PRIMARY OUTCOMES:** There was no difference in the 1- and 3 year graft and patient survival between HIV+ and HIV- KTRs, but the 5-year patient survival was significantly lower in the HIV+ KTRs ($P < 0.05$). Table.
SECONDARY OUTCOMES: The incidence of BPAR was 25% at 1 year and 20% at 3 years. There were no new cases of BPAR at the 5-year follow-up. All BPARs, were T-cell mediated except one case of mixed cellular and antibody-mediated rejection. Of the five HIV+ recipients co-infected with HCV, the incidence of BPAR was 60% within 1-year of KT. The incidence of BKVAN was 19.7 per 100 person-years and 7.9 per 100 person-years for CMV disease during the five-year follow-up.
Conclusions: The mandate of undetectable VL may explain the comparable graft and patient survival rates among HIV+ and HIV- KTRs in the early years post-KT. The lower patient survival at 5 years in HIV+ KTRs compared to HIV-KTRs should be further analyzed. This may be associated with the increased morbidity associated with HIV+ status. Rates of infection were not different between the 2 groups. HIV replication was well controlled in all but one patient due to medication non-adherence. No recurrence of HIVAN was reported. Studies of a larger cohort with a longer follow up periods are needed.

Survival Data

Abstract# 764

Covid-19 Caseload and Management Practices Vary by Program-Level Factors: A Multinational Survey Study

S. Sandal[1], B. Boyarsky[2], P. Chiang[2], A. Massie[2], D. Segev[2], M. Cantarovich[1], *[1]McGill University, Montreal, QC, Canada, [2]Johns Hopkins University, Baltimore, MD*

Purpose: During the pandemic, the COVID-19 patient caseload (CPC) is thought to be highly variable and likely dependant on the cumulative COVID-19 incidence (CCI) of the region. We aimed to capture this variability and COVID-19 treatment practices during the early months of the pandemic.
Methods: From June-September 2020, we conducted a multinational survey of transplant physicians. Of 1,267 physicians contacted, 40.5% from 71 countries participated. CCI was calculated in person per million population (ppm) from March-July and divide into tertiles for the entire cohort (low: <2031ppm, medium: 2032-5400ppm, high: >5400ppm). The primary outcome of interest was a CPC of ≥5 transplant recipients. Logistic regression was used to conduct a comparative analysis. We also asked centers to report their treatment practices by patient symptoms, and rate the likelihood of recommending these treatments on a scale of 1-5 (1 being very unlikely and 5 being very likely).
Results: 70.6% of programs reported seeing recipients with COVID-19 (31.0% <5, 16.2% 5-10, 13.5% 11-20, 6.4% 21-50, and 3.5% >50 cases). When compared with transplant programs from areas with low CCI, those from medium and high CCI areas had 7- and 10-times higher odds of ≥5 CPC, respectively. When compared with low/lower-middle-income countries, upper-middle-income countries and high-income countries had 68% and 71% lower odds for this outcome. More importantly, performing a transplant during this time was associated with 54% lower odds of a higher COVID-19 caseload. In terms of treatments, while reducing immunosuppression was the mainstay, in patients with mild and moderate symptoms, supportive care only (59.3% vs. 23.2%), azithromycin (14.8% vs. 22.8%), and hydroxychloroquine/chloroquine (11.3% vs.17.2%) were the top three choices. In patients with severe symptoms, a wide range of treatments was reported. Supportive care only (4.13±1.22) and Remdesivir (4.13±0.94) were strongly recommended by those that used them.
Conclusions: The CPC is strongly associated with the CCI and income level of a region. But performing a transplant during the early days of the pandemic was not associated with seeing more patients with COVID-19. In transplant recipients with COVID-19, supportive care only and decreasing maintenance immunosuppression are the mainstays of therapy. Should there be a second wave of the pandemic, our findings may help guide clinical practice.

Abstract# 765

Perioperative Anidulafungin Combined with Triazole Prophylaxis for the Prevention of Early Invasive Candidiasis in Lung Transplant Recipients

E. Sartain[1], K. Schoeppler[1], B. Crowther[1], J. B. Smith[2], M. Abidi[3], T. J. Grazia[4], M. Steele[2], T. Gleason[2], K. Porter[2], A. Gray[2], *[1]University of Colorado Skaggs School of Pharmacy, Aurora, CO, [2]Division of Pulmonary Sciences and Critical Care, University of Colorado, Denver, CO, [3]Division of Infectious Disease, University of Colorado, Denver, CO, [4]Baylor University Medical Center, Dallas, TX*

Purpose: Invasive candidiasis (IC) is a substantial cause of morbidity and mortality in lung transplant recipients (LTRs). Post-operative factors, such as prolonged hospital stay, central lines, delayed chest closure, and dehiscence increase early IC risk. Guidelines propose targeted IC coverage in the first 2-4 weeks with fluconazole or an echinocandin. To our knowledge, this is the first study investigating combination triazole/echinocandin use in the early post-LT period.

Methods: We retrospectively assessed a recent protocol at our center. LTRs from 1/2016 to 1/2020 receiving in-hospital anidulafungin and triazole prophylaxis (protocol) were compared to LTRs receiving triazole prophylaxis alone (pre-protocol). Itraconazole was the preferred triazole and was started once tolerating oral medications and continued for at least one year in both cohorts. The primary outcome was IC at 90 days.

Results: A total of 144 LTRs were analyzed. Baseline characteristics were similar, except lower lung allocation score (LAS) and more alternative triazole antifungal use in the protocol group (Table 1). Median duration of anidulafungin was 12 days. There was a numerically lower incidence of IC in the protocol group, although not statistically significant (6% vs 13%, Table 2). Incidence of IFI was lower in the protocol group. However, when controlling for LAS, donor fungal colonization, and dehiscence in multivariable analysis, protocol cohort was not significantly associated with IFI. Triazole antifungal type was not included in this model as a univariate analysis did not reveal a meaningful association with IFI. There was no difference in bacterial infections or all-cause mortality.

Conclusions: In-hospital anidulafungin for early IC prevention offers unclear benefit when used in combination with triazole prophylaxis among LTRs. LAS, donor fungal colonization, and dehiscence were significantly associated with overall IFI; however, protocol cohort assignment was not. Overall, the findings of this single-center study do not support the use of universal triazole/echinocandin prophylaxis in LTRs. Further studies of alternate strategies for early IC prevention in lung transplant recipients are warranted.

Table 1. Baseline Characteristics

	Pre-protocol (n=77)	Protocol (n=67)	P-value
Age, y, median (IQR)	62 (57-65)	61 (56-65)	0.84

Abstract# 766

COVID-19 Infection in Kidney versus Non-kidney Solid Organ Transplant Recipients: A Single Center Study

J. Schaenman[1], H. Byford[2], T. R. Grogan[3], S. Fraschilla[2], K. Meneses[4], J. C. Alejos[5], M. Rivera[6], S. Saab[7], *[1]Infectious Diseases, UCLA, Los Angeles, CA, [2]Transplant Administration, UCLA, Los Angeles, CA, [3]Division of General Internal Medicine and Health Services Research, UCLA, Los Angeles, CA, [4]Liver Transplantation, UCLA, Los Angeles, CA, [5]Pediatric Heart Transplantation, UCLA, Los Angeles, CA, [6]Pediatric Kidney Transplantation, UCLA, Los Angeles, CA, [7]Liver Transplantation, David Geffen School of Medicine at UCLA, Los Angeles, CA*

Purpose: The COVID-19 pandemic has caused significant morbidity and mortality in patients around the world. A significant impact has been observed in immunocompromised patients such as solid organ transplant (SOT) recipients, with increased rates of intubation and mortality compared to non-transplant patients. Our aim was to analyze risk factors, clinical presentation, and outcomes at a single high volume transplant center.

Methods: We reviewed the records of adult SOT recipients during the COVID-19 pandemic from March to October 2020 to identify 143 SOT recipients diagnosed with COVID-19 by SARS-CoV-2 PCR testing, the majority of whom required hospitalization. 12 cases were from pediatric patients and were excluded from further analysis, leaving 131 adult patients for analysis. Recipient demographics, clinical presentation, and outcomes were compared by transplant type.

Results: Kidney transplant recipients comprised the majority of COVID-19 cases (n=87), followed by liver (n=18), lung (n=18), heart (n=7), and intestinal (n=1) transplants. Non-kidney transplant recipients were significantly older than kidney transplant recipients (n=0.005), while kidney transplant recipients were more likely

to be overweight or obese (p=0.007) and have a diagnosis of hypertension (p<0.001) (**Table**). Time between transplant and positive COVID-19 PCR test, sex, ethnicity, incidence of diabetes, and coronary artery disease were similar across transplant types. Presenting symptoms were also comparable, with similar incidence of shortness of breath, cough, fever, nausea and vomiting, diarrhea, and loss of smell or taste. Mortality rates were not significantly different in the kidney compared with the non-kidney transplant recipients (p=0.478).

Conclusions: Although presenting symptoms were similar, kidney transplant recipients with COVID-19 had significant differences in comorbidities compared with non-kidney transplant recipients. Future studies will compare mortality rate in transplant patients compared with non-transplant patients with COVID-19 at our center after adjusting for comorbidities, including diabetes, hypertension and obesity.

Table: Demographic and clinical characteristics of transplant patients with COVID-19

	Kidney transplant recipients (n=87)	Non-kidney transplant recipients (n=44)	p-value
Median age	53	61	**0.005**
Female sex	41.4%	40.9%	1
Median BMI	27.7	25.7	**0.007**
Median months post transplant	52.9	58.8	0.591
Diabetes	58.6%	72.7%	0.114
Hypertension	89.5%	62.2%	**<0.001**
Coronary artery disease	10.3%	18.9%	0.242
Died	11.5%	15.9%	0.478

Abstract# 767

Impact of Sars-cov-2 Infection in Waiting List for Liver Transplantation: A Cohort Study on Clinical Outcomes

A. Sessa, A. Mazzola, B. Granger, D. Wakselman, M. Atif, V. Martinez, M. Mallet Maxime, D. Thabut, O. Scatton, F. Conti, *Hopital Pitie Salpetriere, Paris, France*

Purpose: Infections in cirrhotic patients are associated with an increased risk of liver-related complications (LRC) and mortality. Limited data regarding the prevalence of Coronavirus disease (COVID-19) in cirrhotic patients' awaiting liver transplantation (LT) are available. The aim of this study was to evaluate the prevalence of Sars-cov2 in a cohort of cirrhotic patients and its impact on LRC rate and on LT.

Methods: We retrospectively included 187 waitlist patients for LT from 24-January-2020 (2020-cohort) and 123 patients from 24-January-2019 (2019-cohort). All 2020-cohort patients were screened for COVID-19 symptoms with a survey. COVID-19 infection was defined by a positive PCR assay for SARS-CoV-2 on nasopharyngeal swab or the positivity for specific antibodies or typical lung lesions on CT scan. We also assessed the indirect impact of Sars-Cov2 infection on LRC and LT rate, estimated by competitive risk survival analyses in 2020-cohort vs. 2019-cohort (Fine and Gray method).

Results: In 2020-cohort, 72.7% (n=136) of patients were male with mean age of 55.5±12, 47.2% (n=85) patients have alcohol and/or NASH related cirrhosis, with a median MELD score of 14.1±7.4. 45.5% (n=71), 38.5% (n=60) and 14.8% (n=23) of patients were A, B and C for Child-Pugh-score, respectively. 172 patients responded to survey and 22% (n= 38) had symptoms. 20/38 patients were tested for Sars-Cov2 and 4 patients were positive. 3/4 patients with COVID-19 disease needed hospitalization and 1 intensive care support. No death was reported and 1 patient was LT. The 2020-cohort and 2019-cohort were comparable for sex (p=0,6), age (p=0.7), comorbidities (p=0.2) and Child-Pugh-score (p=0.2). The cumulative incidence of LRC was not significantly higher in the 2020-cohort vs. 2019-cohort (SHR 0.65, 95% CI 0.36-1.15, p=0.138). The cumulative incidence of LT was significantly lower in the 2020-cohort than in the 2019-cohort (SHR0.21, 95% CI 0.13-0.33, p<0.001).

Conclusions: Our study reported a low prevalence rate of Sars-Cov2 infection in a cohort of cirrhotic patients waiting for LT. No Sars-Cov2 infection direct or indirect impact on mortality and LRC rate was reported. However, a significant shortage of LT was found in 2020 cohort.

Abstract# 768

Delayed Valganciclovir Initiation and the Incidence of Cytomegalovirus Infection in Liver Transplant Recipients

S. Shaikh, P. Kawewat-Ho, Y. Genyk, L. Sher, J. Kahn, L. Rivera, *Keck Medical Center of USC, Los Angeles, CA*

Purpose: Opportunistic infections remain a significant burden after liver transplantation, particularly cytomegalovirus (CMV) infection. With the use of valganciclovir (VGCV), the incidence of CMV infection post-liver transplantation has reduced significantly, however the optimal time to initiate CMV prophylaxis (ppx) in liver transplant recipients is unclear and VGCV use is limited by cost and side effects including leukopenia and thrombocytopenia. This study evaluates timing to CMV ppx initiation and outcomes in liver transplant recipients.

Methods: In this single center retrospective cohort study of adult liver transplant recipients between August 2018 and May 2019, patients who received immediate VGCV (within 6 days post-transplantation) were compared to those who received delayed VGCV (7-10 days post-transplantation) for CMV ppx. Patients included in this study received VGCV within 10 days of transplant and continued through at least 3 months. Exclusion criteria included patients with a prior history of transplantation, simultaneous kidney and liver transplantation, VGCV initiation greater than 10 days after liver transplant, and patients with unknown recipient CMV serologies. The primary outcome evaluated was the incidence of CMV viremia. Secondary endpoints included CMV syndrome, CMV tissue-invasive disease, biopsy proven acute rejection episodes (BPAR), allograft loss, and 6-month all-cause mortality.

Results: The average time to initiation of VGCV ppx in the immediate group was 3.71 days ± 1.65, compared to 7.76 days ± 0.96 in the delayed group. CMV viremia occurred in 14.3% and 12.1% of patients in the immediate and delayed ppx groups respectively (p > 0.99). No differences were found in secondary outcomes. We estimated a cost savings of $429.62 per patient.

Conclusions: Our study demonstrates that timing to CMV ppx initiation with valganciclovir does not influence the incidence of CMV viremia in adult patients after liver transplantation, and is an area for cost containment for transplant centers.

Table 1. Primary Outcome

Outcome	Immediate ppx (n=21)	Delayed ppx (n=33)	p-value
CMV Viremia	2 (14.2%)	4 (12.1%)	>0.99

Table 2. Secondary Outcomes

Outcome	Immediate ppx (n=21)	Delayed ppx (n=33)	p-value
CMV Syndrome	2 (9.5%)	3 (9.1%)	>0.99
Tissue-invasive disease	0	1 (3.0%)	>0.99
BPAR	1 (4.7%)	4 (12.1%)	0.63
Allograft loss	0	1 (3.0%)	>0.99
Death	0	1 (3.0%)	>0.99

Abstract# 769

Quantiferon-tb Gold Plus in Liver Transplant Candidates: Single-center Experience

J. Simkins[1], M. A. Mendoza[1], A. Chandorkar[1], Y. Natori[1], S. Anjan[1], L. R. Arosemena[1], R. Vianna[2], *[1]Medicine, University of Miami, Miami, FL, [2]Surgery, University of Miami, Miami, FL*

Purpose: QuantiFERON-TB (QFT) is the preferred diagnostic test for latent tuberculosis infection (LTBI). The QFT-Gold Plus (QFT-Plus) data in OLT candidates is limited.

Methods: Our hospital replaced QFT-Gold In-Tube (QFT-GIT) with QFT-Plus in 3/2019. We assessed QFT-Plus results performed prior to OLT among patients that were transplanted between 4/2019 and 8/2020 at a large transplant center. We obtained previous QFT-GIT results if available to assess for discordant results. Chest-x-rays (CXR) and chest CT scans performed within 1 year prior to OLT were obtained to assess for LTBI signs (nodules, pleural thickening, and scarring). The plan by the infectious diseases (ID) team for those OLT patients with positive or indeterminate QFT-Plus was evaluated.

ID

Results: We assessed 170 OLT recipients [122(72%) Male, 94(55%) Hispanic]. Median age was 58 (range: 21-75) years. QFT-Plus was performed in 124(73%) patients [86(69%) were tested once, 28(23%) twice, 8(6%) thrice and 2(2%) four times]. Eight out of 124(6%) had positive, 20(16%) indeterminate and 96 (77%) negative QFT-Plus. One of the QFT-Plus-positive patients, tested negative 9 days after testing positive, and 9(45%) of the QFT-Plus-indeterminate patients converted to negative (Table 1). Previous QFT-GIT were performed in three QFT-Plus-positive patients (it was positive in 2 and negative in 1), in two QFT-Plus-indeterminate patients (it was negative in both), and in 16 QFT-Plus-negative patients (it was positive in 1 and negative in 15). There was no difference in the prevalence of LTBI-suggestive radiographic findings between patients with positive and negative QFT-Plus [CXR: 1/8(13%) vs. 8/96(8%), P=0.53 and CT scan: 4/5(80%) vs. 32/35(91%), P=0.43]. ID team recommended isoniazid for 9 months for 7(88%) and 9(45%) patients with positive and indeterminate QFT-Plus, respectively. Isoniazid was not recommended in 1 case of positive QFT-Plus (previously treated).

Conclusions: QFT-Plus appears to be an acceptable test for LTBI diagnosis in OLT candidates. In our cohort, indeterminate QFT-Plus was common. QFT-Plus conversion from indeterminate to negative was frequent.

Table 1. Liver transplant recipients with positive and indeterminate QFT-Plus

N° Patients	1st test	2nd test	3rd test	4th test
1 patient	Positive	Negative	X	X
7 patients	Positive	X	X	X
8 patients	IND	Negative	X	X
1 patient	IND	Negative	IND	X
2 patients	IND	IND	IND	IND
2 patients	IND	IND	IND	X
1 patient	IND	IND	X	X
4 patients	IND	X	X	X
1 patient	Negative	IND	X	X
1 patient	Negative	IND	IND	X

IND: Indeterminate

Abstract# 770

Nosocomial COVID-19 Among Hospitalized Solid Organ Transplant Recipients

J. T. Swan[1], A. Tran[1], E. Rizk[2], E. A. Graviss[1], A. Drews[2], K. A. Grimes[2], D. T. Nguyen[1], S. G. Yi[2], R. R. McMillan[2], F. Yuan[1], I. Carrillo[3], G. Book[3], F. R. Zabaneh[3], L. W. Moore[1], A. O. Gaber[2], *[1]Houston Methodist Research Institute, Houston, TX, [2]Houston Methodist Hospital, Houston, TX, [3]Houston Methodist, Houston, TX*

Purpose: This study aimed to identify probable cases of nosocomial Coronavirus Disease 2019 (COVID-19) among hospitalized solid organ transplant (SOT) recipients.

Methods: All hospitalized SOT recipients diagnosed with COVID-19 by polymerase chain reaction (PCR) from March 11, 2020 to August 24, 2020 were evaluated. Potential nosocomial cases included admissions where the first positive PCR occurred on hospital day 3 or later (intra-admission) or within 14 days of a previous hospital discharge (inter-admission). Two infectious disease specialists independently adjudicated all potential cases into four categories (definitely community-acquired, likely community-acquired, likely hospital-acquired, and definitely hospital-acquired) using systematic chart review of symptom onset, radiographic findings, and community risk factors. Discrepancies were resolved by a third investigator.

Results: Of 132 hospitalized SOT recipients diagnosed with COVID-19, nosocomial infections were apparent in 19 (14%; Figure 1). Intra-admission cases (n=11, 4 likely hospital-acquired and 7 definitely hospital-acquired) were diagnosed a median (IQR) of 43 (8 to 53) days after admission. Inter-admission cases (n=8, all likely hospital-acquired) had 5 (3 to 10) days of hospital care in the 14 days preceding diagnosis. The proportion of COVID-19 infections classified as nosocomial varied by time from most recent transplant until diagnosis (P<0.001) and transplant type (P<0.001; Table 1). Probable nosocomial infections peaked in June and gradually declined.

Conclusions: Despite infection control measures to sequester SOT recipients and their nurses on dedicated transplant floors and provide patients and healthcare workers with screening, COVID-19 may have been acquired during healthcare interactions in 14% of hospitalized SOT recipients diagnosed with COVID-19. Vaccination against COVID-19 for front-line healthcare workers is important for protection of SOT recipients.

Proportion of COVID-19 infections that were nosocomial			
		Patients with COVID-19, *n*	Patients with nosocomial COVID-19, *n* (row %)
Transplant type	Heart only	9	4 (44%)
	Lung only	15	6 (40%)
	History of >1 organ	17	3 (18%)
	Liver only	17	3 (18%)
	Kidney only	74	3 (4%)
Time from the last transplant to COVID-19 diagnosis	≤ 1 year	23	9 (39%)
	> 1 year	109	10 (9%)

Abstract# 771

Cytomegalovirus Nephritis: Epidemiology and Outcomes of an Uncommon Diagnosis

K. J. Swanson, A. Djamali, A. Ghaffar, F. Aziz, N. Garg, M. Mohamed, D. A. Mandelbrot, M. Jorgensen, S. Parajuli, *Division of Nephrology, University of Wisconsin-Madison, Madison, WI*

Purpose: Cytomegalovirus (CMV) nephritis is an uncommon end-organ manifestation of CMV disease. Due to this, associated outcomes have not been completely elucidated.

Methods: This was a single-center case-series of adult kidney transplant recipients (KTR)s diagnosed with biopsy-proven CMV nephritis from 1997 to 2020. Primary objective was to describe epidemiology and outcomes associated with this diagnosis.

Results: 12 KTRs had biopsy-proven CMV nephritis within the study period, with mean interval from transplant to diagnosis of 6.8 ± 4.3 mos. 5 KTRs (42%) were high risk for CMV (D+/R-); the remaining 7 intermediate. Median interval from transplant to first detectable CMV was 3.5 mos (IQR = 3.9 mos). As CMV detection has evolved over time, only 3 KTRs underwent quantitative PCR testing. Mean CMV level at biopsy in these patients was 2.4 million ± 3.5 million IU/mL. Most KTRs were symptomatic (n =10, 83%) mainly with diarrhea (n = 7, 70%), fever, fatigue, and nausea (all n =3, 30%). The most common lab findings were AKI (n=10, 83%) and leukopenia (n = 4, 33%). Main biopsy features were glomerular CMV inclusions (n = 7, 58%) followed by the tubulointerstitial inclusions (n = 6, 50%). The most common concomitant end-organ CMV manifestations were gastrointestinal, with 2 cases of biopsy-proven CMV colitis (16%) followed by esophagitis (n=1, 8%). No cases of CMV retinitis, hepatitis or pneumonitis were seen. 11 KTRs were treated with IV ganciclovir. 6 (55%) received IVIG. Antimetabolite discontinuation occurred in 83% (n= 10) in response to CMV diagnosis. A renal biopsy of one patient is presented below in Figure 1. 11 KTRs (92%) experienced graft failure, of which 5 (42%) were death-censored. 5 KTRS (42%) had rejection: 3 patients having concurrent rejection at the time of index biopsy, 2 had rejection at 2 and 3 months post biopsy. Mean SCr at 12 mos post-index biopsy was 1.8 ± 0.6 mg/dL (n = 8) compared to a mean SCr at the time of biopsy of 3.0 ± 1.5 mg/dL.

Conclusions: CMV nephritis is rare but can cause significant graft dysfunction associated with poor patient/allograft outcomes. Unifying characteristics include CMV high risk status, high viral load, AKI and leukopenia in the setting of symptomatic disease. Early identification and prompt treatment of CMV infection may prevent end organ manifestations and improve outcomes.

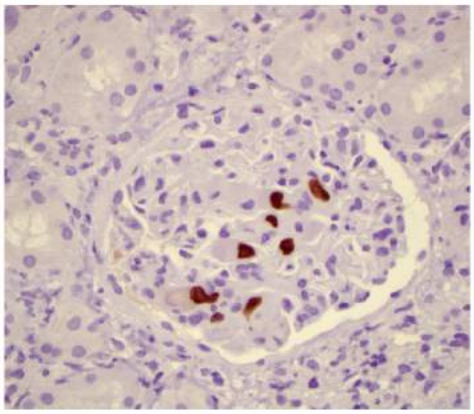

Figure 1. Cytomegalovirus nephritis. Kidney allograft biopsy with segmental intracapillary CMV-positive cells in a representative glomerulus. In total, eight glomeruli had these findings. Immunohistochemical stain (IHC).

Abstract# 772

Changes in Cytomegalovirus Specific T Cell Immunity With Immunomodulation in Serodiscordant High Risk Transplant Recipients

T. Tinkham, C. Song, R. Winstead, I. Yakubu, A. Brown, S. Sterling, G. Gupta, D. Kumar, *Virginia Commonwealth University Health, Richmond, VA*

Purpose: Cytomegalovirus (CMV) infections cause significant morbidity and mortality among all solid organ transplant recipients. CMV discordant (D+/R-) recipients are at higher risk of developing CMV viremia after cessation of prophylaxis. CMV specific T cell immunity has been shown in many publications to predict those at highest risk for CMV associated events. However it is unknown if changes in maintenance immunosuppression guided by CMV T cell immunity may lead to fewer CMV events as a result of improved immunity.

Methods: This is a retrospective single center analysis of 38 CMV discordant recipients between October 2018 and June 2020 that received a CMV T cell immunity assay prior to cessation of universal prophylaxis. 32 (84%) were kidney recipients, 3 (8%) liver, 3 (8%) simultaneous liver-kidney and 1 (3%) simultaneous pancreas-kidney. CMV viremia was defined by positive CMV PCR (>137 U/mL) and/or symptomatic disease. Recipients who had low T cell immunity (CMV CD4/CD8 < 0.20) on initial testing underwent reduction of antimetabolite (MMF) dose if deemed appropriate based on immunological and hematological parameters. Subsequent CMV T cell immunity was tested after reduction of immunosuppression.

Results: The majority of CMV discordant recipients were male (N=26, 68%), African American (N=22, 58%), and received rabbit anti-thymocyte globulin induction (N=32, 84%). At a median follow-up of 9 months (IQR 4, 24), six (16%) episodes of CMV viremia were observed. Those who developed viremia had significantly lower CMV CD8 specific T cell immunity compared to those who did not develop viremia (0.14±0.20 vs. 1.54±4.09, p=0.03) with a similar though non-statistically significant CD4 specific T cell immunity (0.057±0.03 vs. 0.33±1.07, p=0.08). Thirteen (34%) recipients underwent repeat testing at an average of 78±44 days after initial test. Of the 13, nine (69%) had a median MMF dose reduction of 500 mg (IQR 500,750) while four (31%) had no dose reduction. On subsequent testing those with reduction of MMF had an improvement in both CD8 [0.01 (IQR 0, 0.04) to 0.05 (IQR 0, 1.17) p=0.07] and CD4 [0.04 (IQR 0.02, 0.09) to 0.1 (IQR 0.06, 0.25) p=0.007] specific T cell immunity. Conversely, those with no change in MMF dose had no discernable improvement in both CD4 [0.02 (IQR 0, 0.09) to 0.06 (IQR 0.01, 0.25), p=0.11] and CD8 [0.03 (IQR 0.02, 0.04) to 0.04 (IQR 0.02, 0.12) p=0.17] specific T cell immunity. No significant difference in acute rejection episodes occurred between groups.

Conclusions: This single center study confirms previous findings that CMV high-risk recipients with low CMV T cell immunity had higher rates of CMV viremia. More importantly, we demonstrated that CMV specific T cell immunity may improve with changes to maintenance immunosuppression. Further studies are required to see if serial T cell immunity assays may be used as adjunctive data to adjust maintenance immunosuppression to reduce the risk of CMV events.

Abstract# 773

Ganciclovir Therapeutic Drug Monitoring in Obese Adults Patients - Opportunity for Clinical Utility

Y. Tran[1], S. Bernard[1], R. W. Stevens[1], L. Myhre[1], R. Razonable[2], *[1]Department of Pharmacy, Mayo Clinic, Rochester, MN, [2]Division of Infectious Diseases, Department of Internal Medicine, Mayo Clinic, Rochester, MN*

Purpose: Ganciclovir (GCV) is the drug of choice for the treatment of cytomegalovirus (CMV) infection; optimal dosing of GCV in the obese patient population is unknown. The primary objective of this study is to assess the frequency of ganciclovir therapeutic drug monitoring (TDM) obtained in obese patients with prolonged use. Secondary objectives are to explore the role of GCV TDM and its associated clinical outcomes, understand barriers to clinical utilization of GCV TDM, and improve our institutional protocol.

Methods: This was a retrospective, multicenter chart review spanning Jan 2014-Jun 2020. Patients were included if they were adults with obesity (BMI ≥ 40 kg/m^2 and/or actual body weight ≥ 120 kg) and GCV therapy indicated for treatment of CMV viremia, CMV syndrome, suspected or biopsy-proven CMV invasive disease, or other viruses. A qualitative survey among clinical pharmacists was also completed to assess the perspective and practices with regards to GCV TDM.

Results: This study screened 447 patients receiving GCV. A total of 23 (5%) were obese, with 2 patients having 2 separate courses of induction (Figure 1). Baseline characteristics are in Table 1. The majority of episodes were indicated for the treatment of CMV viremia (n=9, 36%) or suspected CMV-tissue-invasive disease (n=7, 28%). Among the 18 patients with duration of therapy ≥ 14 days, GCV TDM was completed for 3 patients (17%) (Figure 2) and time from treatment initiation to TDM ranged from 21 to 18 days (Table 3). The pharmacist survey revealed support for use of GCV TDM; however, additional evidence was desired (Table 4).

Conclusions: GCV TDM in obese patients is potentially underutilized at our institution. This is complicated by a limited number of obese patients contracting CMV. This topic requires further study with additional patients undergoing GCV TDM to explore safety and efficacy outcomes relevant to GCV TDM in the obese patient population.

Table 1. Baseline patient characteristics	
Parameters	Results (n =23)
Age (years) median, range	47 (20 – 78)

Ganciclovir TDM result	Patient 1	Patient 2	Patient 3
Time from treatment initiation to TDM (days)	126	186	21
Trough serum concentration			
Below target (< 1 mcg/ml)		< 1.0	
Within target (1.0 - 3.0 mcg/ml)	1.2		
Above target (> 3.0 mcg/ml)			7.7
Peak serum concentration		N/A	N/A
Below target (< 3.0 mcg/ml)			
Within target (3.0 - 12.5 mcg/ml)	6.6		
Above target (> 12.5 mcg/ml)			

Table 4. Pharmacists survey results
Benefits of ganciclovir TDM among obese patients
• Appropriate dosing to balance between efficacy and safety
• Prevention of toxicity
• Get therapeutic levels
• Achieve treatment goal in viral clearance
Challenges in ganciclovir TDM implementation
• Lack of supporting evidence about the relationship of ganciclovir level and efficacy
• Unclear guidance with the term "consider"
• Unfamiliarity with ganciclovir TDM among pharmacists
• Coordination between outpatient clinic and lab operation

Abstract# 774

Variation of Mortality from SARS-CoV-2 Infection in Kidney Transplant Recipients Over the Course of the Pandemic

Y. Al Azzi, C. Pynadath, P. Loarte, O. Alani, L. Liriano-Ward, M. Ajaimy, R. Bartash, J. Graham, M. Le, H. Yaffe, S. Greenstein, J. Rocca, M. Kinkhabwala, E. Akalin, *Montefiore Medical Center, New York, NY*

Purpose: We aimed to investigate the mortality from SARS-CoV-2 in kidney transplant recipients in the Bronx, New York, one of the epicenters of the pandemic over the period of the pandemic.
Methods: Between March 16 and November 30, 2020, 158 patients were tested positive by SARS-CoV-2 RT-PCR.
Results: 94 (59.5%) were male, at a median age of 62 years old (IQR: 51-71), predominantly Hispanic (54.4%) and African American (29.7%). 127 patients were admitted to the hospital and 29 were observed at home. 75.3% received a deceased-donor renal transplant, 57% received anti-thymocyte globulin induction. Most patients were on triple immunosuppression (94.3% on calcineurin inhibitors, 86.7% on anti-metabolite, 96.7% on prednisone). Hypertension was present in 96.2%, diabetes mellitus in 62.7%, heart disease in 19.6% and lung disease in 8.9% of the patients. The figure shows the number of RT-PCR positivity and mortality over the course of the pandemic starting on March 16, 2020. A total of 50 (31.6%) died as of November 30, 2020. The mortality rate was 40% (17/43) in patients diagnosed between March 16 and 31,2020, 39% (23/59) in patients diagnosed between April 1 and 15,2020 and 29% (7/24) in patients diagnosed between April 16 and 30, 2020. Since May 1st 2020, the mortality rate has significantly decreased to 9% (3/32).
Conclusions: In summary, mortality from SARS-CoV-2 infection in kidney transplant recipients was higher during the first 6 weeks of the pandemic and has significantly decreased over time. This could be explained by initial exposure of the patients with higher viral load due to lack of personal protection and social distancing due to the fact that there is no current proven treatment for SARS-CoV-2 infection and clinical approach to patients has not been changed since the beginning of the pandemic.

Abstract# 775

Risk Factors of COVID-19 in Kidney Transplant Recipients

M. M. Alkadi, E. Abuhelaiqa, M. Asim, O. Fituri, R. Elidrisi, R. Abdul Rahiman, M. Elshirbeny, M. Othman, A. Hamad, A. Ashour, A. Hamdi, A. Nauman, H. Tohid, M. Jarman, H. Al-Malki, *Nephrology-Medicine, Hamad Medical Corporation, Doha, Qatar*

Purpose: Kidney transplant recipients have been shown to develop a severe form of coronavirus disease (COVID-19) that poses a significant mortality risk. The aim of this study was to evaluate risk factors associated with acquiring COVID-19 in our kidney transplant population.
Methods: We retrospectively reviewed the medical records of all kidney transplant recipients in our national transplant registry. There were 249 out of 693 kidney transplant recipients who underwent SARS-CoV-2 infection testing by August 1st, 2020. All testing was done by government using RT-PCR of throat and nasal swabs. Forty-three of the tested patients had positive COVID-19 (17%), while the remaining 206 were negative. Mann-Whitney and Fisher's exact tests were used to study the different continuous and categorical variables, respectively.
Results: Among patients tested for COVID-19, Asian ethnicity (37% vs. 16%, P=0.003), history of hypertensive nephropathy (23% vs. 9%, P=0.01) and deep vein thrombosis (12% vs.1%, P=0.002) were statistically significant in COVID-19 positive group compared to COVID-19 negative group. Tacrolimus trough level at the time of COVID-19 testing was also significantly higher in COVID-19 positive patients (7.7 ng/mL vs. 6.6 ng/mL, P=0.03). Recipient age, gender, year of transplant, donor type, maintenance immunosuppression, flu vaccine within 1 year and use of ACE inhibitors or ARBs were all similar in both groups. Most patients with positive COVID-19 were symptomatic at the time of testing compared to negative patients (84% vs. 18%, P=0.0001). However, close contact with positive COVID-19 people was similar in both groups (14% vs. 14%, P=1).
Conclusions: Prevention and reduction of COVID-19 infection development is crucial in kidney transplant recipients to avoid unfavorable outcomes. With the widespread of COVID-19 worldwide, avoiding exposure might not be possible. Our results suggest that targeting lower tacrolimus trough levels may reduce the risk of acquiring SARS-CoV-2 infection.

Variable	Positive N = 43	Negative N = 206	P value

Abstract# 776

Impact of Early versus Late Ureteric Stent Removal and Antibiotic Prophylaxis on Urinary Tract Infection Incidence in Kidney Transplant Adult Recipients

K. Althiab[1], B. Alqahtani[2], R. Alotaibi[3], R. Alhussein[3], R. Almuhiteb[2], L. Alnajjar[2], M. Alqahtani[2], K. Bin Saad[4], W. Ohali[4], A. Tamimi[4], M. N. Almarastani[4], S. Kashkoush[4], G. Aboalsameh[4], M. Shaheen[4], M. Tawhari[4], A. Altheaby[4], Z. Arabi[5], *[1]Pharmaceutical Care Services, King Abdulaziz Medical Center, Riyadh, Saudi Arabia, [2]College of Pharmacy, Princess Nourah bint Abdulrahman University, Riyadh, Saudi Arabia, [3]bCollege of Pharmacy, Princess Nourah bint Abdulrahman University, Riyadh, Saudi Arabia, [4]Organ Transplant Center, King Abdulaziz Medical Center, Riyadh, Saudi Arabia, [5]King Abdulaziz Medical Center, Riyadh, Saudi Arabia*

Purpose: To investigate the impact of early Vs. late ureteric stent removal while utilizing various antibiotic prophylaxis regimens on UTI in renal transplant recipients.

Methods: A retrospective study of 279 renal transplantation from January 2017 to May 2020 with 6 months follow-up, that was conducted at King Abdulaziz Medical City, Riyadh, Saudi Arabia. Patients were divided into two groups: early stent removal group (<3 weeks) or late stent removal group (>3 weeks). Peri-transplant antibiotic prophylaxis included Cefazolin or Ampicillin plus Cefotaxime while the post-transplant included single strength Bactrim or double strength Bactrim plus Norfloxacin.

Results: Ninety-seven (35%) patients developed UTI (mean age 45.8±16.0 years; 60 [61.9%] women). The mean stent removal time was 15.3±4.8 days in the 1st group and 49.7±25.9 days in the second. Among 114 patients in the 1st group, 32% had UTI Vs 37% of 165 in the second. The rate of UTI before removing the stent was 20% and 80% in the early and late group, respectively. Asymptomatic UTI was observed in 70% and 34% before stent removal in the early and late group, respectively (*P*=0.037), and in 27% and 33% after stent removal in the early and late group, respectively (*P*=0.692). No difference in the distribution of multidrug resistant organisms among the early and late groups (47.50% Vs 33.30%, respectively; *P*=0.205), and before or after stent removal (65.90%% Vs 51.80%, respectively; *P*=0.213). Predictors for UTI were age > 40 years (odds ratio, 2.028; 95% CI, 1.098-3.745; P=0.024), female gender (odds ratio, 5.165; 95% CI, 2.768-9.636; *P*<0.001), and type II diabetes (odds ratio, 2.023; 95% CI, 1.003-4.08; *P*=0.049). Type of post-transplant antibiotic prophylaxis was not a significant predictor for UTI (odds ratio, 1.507; 95% CI, 0.735-3.091; *P*=0.263).

Conclusions: Early stent removal is associated with lower rate of UTI without significant effect form the choice of prophylactic antibiotics.

Abstract# 777

Methenamine for the Prevention of Recurrent UTIs Post-Renal Transplant

A. Bigness[1], S. Mohamed[2], S. Mandala[1], N. Khodieva[2], K. Robichaux[3], H. Mohammed[1], J. Buggs[4], A. Kumar[1], A. Brueckner[5], L. Bowman[5], *[1]Morsani College of Medicine, University of South Florida, Tampa, FL, [2]College of Public Health, University of South Florida, Tampa, FL, [3]Honors College, University of South Florida, Tampa, FL, [4]Transplant Surgery, Tampa General Hospital, Tampa, FL, [5]Department of Pharmacology, Tampa General Hospital, Tampa, FL*

Purpose: Urinary tract infections (UTIs) are a highly prevalent postoperative complication in kidney transplant recipients (KTRs), occurring in approximately 34% of patients. The common method for UTI prophylaxis is systemic antibiotics; however, this practice is associated with an increased risk of drug resistance. Methenamine has been proposed as a bacteriostatic alternative for the prevention of recurrent UTIs, but data is limited in the KTR population. The purpose of this study was to evaluate differences in outcomes in kidney transplant patients before and after the implementation of methenamine for recurrent UTIs.

Methods: A retrospective, single-center, pre-post cohort study of adult (>18 years old) KTRs transplanted from 2012-2019 who received methenamine for the prevention of recurrent UTIs was conducted. The primary endpoint was the change in UTI incidence after methenamine initiation.

Results: A total of 902 patients received a kidney transplant during the study period, of which, 38 patients received methenamine for the prevention of recurrent UTIs. After initiation of methenamine, there was a significant decrease in the incidence of UTIs (2.42 vs 0.77, p<0.0001). Additionally, there were significantly fewer overall admissions (3.39 vs 1.5, p<0.001) and admissions for UTIs (1.47 vs 0.44, p<0.0001) post-methenamine initiation. Methenamine had one reported adverse event (rate of 2.8%) with no increase in crystalluria (p= 0.995).

Conclusions: Methenamine boasts a low-risk profile and was shown to have no increased incidence of crystalluria. There was an associated decrease in the average number of UTIs, admissions, and admissions for UTI after patients were initiated on methenamine. This study adds to the paucity of data on methenamine for the prevention of recurrent UTIs in KTRs. Methenamine is a promising prophylactic agent that should be considered for use in KTRs. Future studies like a randomized controlled trial are necessary to ascertain methenamine's full prophylactic capabilities in a prospective trial.

Abstract# 778

Outcomes Among CMV Mismatched and Highly Sensitized Kidney Transplant Recipients Who Develop Leukopenia or Neutropenia

S. Brar[1], R. Berry[2], A. Raval[3], Y. Tang[3], F. Vincenti[2], N. Skartsis[2], *[1]University of British Columbia, Vancouver, BC, Canada, [2]University of California, San Francisco, San Francisco, CA, [3]Merck and Co., Inc., Kenilworth, NJ*

Purpose: Kidney transplant recipients (KTRs) who receive antiproliferative agents for immunosuppression and valganciclovir for CMV prophylaxis are at high risk of

developing leukopenia and neutropenia. Limited data exist on the extent to which this results in a dose reduction or discontinuation of mycophenolate acid and/or valganciclovir.

Methods: This is a retrospective cohort study of 573 KTRs at University of California, San Francisco Medical Center between 2012 and 2018, who were CMV mismatched (D+/R-) or had a PRA ≥ 80%. Individuals with HIV, Hepatitis B and C, and primary non-function were excluded. KTRs were followed for ≥ 1-year post-transplant. Neutropenia and leukopenia were defined as an absolute neutrophil count < 1000 cells/microliter and an absolute white blood cell count < 3500 cells/microliter, respectively. Cox proportional hazards regression models using leukopenia or neutropenia as a time-varying predictor were used to determine the risk of mycophenolate acid and valganciclovir dose reduction or discontinuation and use of granulocyte colony stimulating factor (G-CSF). Models were adjusted for recipient demographics, transplant characteristics, and duration of valganciclovir prophylaxis.

Results: Study cohort consisted of 233 and 379 KTRs who were CMV mismatched and/or were highly sensitized, respectively. Mean follow-up was 3.7 (SD, 1.8) years. The mean age of the cohort was 50.4 (13.1) years and 57.6% were female. A total of 468 (81.7%) of the participants had leukopenia, 208 (36.3%) had neutropenia and 108 (18.8%) had CMV viremia. Neutropenia modeled as a time varying predictor was associated with an increased risk of both valganciclovir [adjusted hazard ratio, aHR: 13.0, 95% CI: 7.9-21.6] and mycophenolate acid [aHR 10.8, 95% CI: 6.9-17.0] discontinuation. Neutropenia was also associated with more G-CSF use [aHR 45.5, 95% CI: 27.9-74.0] and hospitalizations [aHR 3.3, 95% CI: 2.1-5.1]. Similar findings were shown for leukopenia.

Conclusions: Leukopenia and neutropenia occur frequently after kidney transplantation in patients who are CMV mismatched or highly sensitized, and this leads to discontinuation of mycophenolate acid and/or valganciclovir and increases the utilization of G-CSF. Early modification of antiproliferative immunosuppression and/or antiviral drugs for CMV may lead to long-term adverse outcomes.

Abstract# 779

Clinical Characteristics, Risk Factors and Outcomes of Norovirus Infection in Renal Transplant Patients: A Retrospective Single Center Study

T. Brooks[1], T. Crilley[1], B. Gaglani[2], N. Jakharia[2], *[1]Department of Internal Medicine, Wake Forest University Baptist Medical Center, Winston Salem, NC, [2]Division of Infectious Diseases, Wake Forest University Baptist Medical Center, Winston Salem, NC*

Purpose: Norovirus gastrointestinal infection has been identified as a cause of significant morbidity among immunocompromised hosts, particularly hematopoietic stem cell transplant (HSCT) and solid organ transplant (SOT) recipients. It can cause severe disease with prolonged diarrhea, which is often complicated by dehydration, malnutrition, kidney injury, rejection, and mortality. We describe the clinical characteristics and outcomes of this infection in a large cohort of kidney transplant patients.

Methods: We conducted a single center, retrospective chart review study of adult patients (age >18 years) who were recipients of kidney or kidney-pancreas transplant and had norovirus infection, diagnosed by positive PCR testing during the time period from January 2015 through March 2020.

Results: A total of 72 renal transplant recipients were reviewed. 37(51%) patients were female. Median age was 53 years. 26% allografts were from living donors. 11% had simultaneous pancreas kidney transplant. Most patients (95%) received T cell depleting agents for induction. 28% had other concomitant infections at the time of diagnosis. The mean duration of diarrhea was 54 days (0-771) and 24 (33.3%) patients had diarrhea for longer than 30 days. 47 patients (65%) were hospitalized, of which 14.9% required ICU level of care. 70% required administration of IV fluids. Average length of stay was 7.5 days (1-111). Immunosuppression was reduced in 64% of the patients. 12 (17%) patients received nitazoxanide. Renal failure (defined as > 20% reduction in baseline GFR) occurred in 24 (35.3%) patients, of which 16.7% required renal replacement therapy. The average weight loss was 2.3% and 0.3% of total body weight(TBW) at 1 and 6 months post diagnosis respectively. In patients with diarrhea for longer than 30 days, average weight loss was 3.7% and 2% of TBW at 1 and 6 months respectively. 5 patients had biopsy proven allograft rejection by 1 year of diagnosis and 8 received treatment for rejection. 6 (9.1%) patients died by 1 year and one was attributed to norovirus infection.

Conclusions: Norovirus infection led to severe diarrheal disease in our cohort. Significant number of patients developed prolonged diarrhea, acute kidney injury, and required hospitalization. Reduction of immunosuppression was the most commonly implemented strategy.Clinicians must have a high suspicion for this illness and obtain PCR testing for timely diagnosis and appropriate management.

Abstract# 780

Evaluation of Low Dose Famciclovir as Herpes Simplex Virus and Varicella Zoster Virus Prophylaxis in Cytomegalovirus Low Risk Solid Organ Transplant Recipients

M. Cote, A. Cubley, C. Rogers, S. Shao, C. N. Kotton, *Massachusetts General Hospital, Boston, MA*

Purpose: Famciclovir is recommended for herpes simplex virus (HSV) and varicella-zoster virus (VZV) prophylaxis in cytomegalovirus (CMV) low risk (both donor and recipient CMV seronegative) solid organ transplant (SOT) recipients in current guidelines, however there is no data evaluating its use in SOT recipients. At our institution, we use famciclovir dosed at 500 mg daily for 3 months as a convenient option, with the lowest pill burden, for HSV/VZV prophylaxis. We aimed to evaluate the efficacy and safety of once daily famciclovir for antiviral prophylaxis, in addition to conducting a multicenter provider survey on antiviral prophylaxis in CMV low risk SOT recipients.

Methods: Two-part analysis was done, consisting of a retrospective chart review of kidney transplant recipients discharged on famciclovir between April 2, 2016 and August 31, 2018 and a national provider survey. The primary outcome of the chart review was the incidence of HSV, VZV or CMV infection at 12 months post-transplant. Secondary outcomes included immunosuppression doses and levels, famciclovir dose, hematology cell counts, and renal function at predetermined time points post-transplant. Rates of acute rejection, graft loss/failure, and incidence of famciclovir premature discontinuation were also collected.

Results: Of the 78 patients included in our retrospective chart review, one patient (1.3%) developed a VZV infection at 12 months post-transplant after completing prophylaxis (Table 1). One patient (1.3%) required premature discontinuation of famciclovir due to concern for acute interstitial nephritis. There was a low incidence of additional safety endpoints including graft loss, rejection, death with functioning graft and filgrastim administration. Providers from forty-five transplant centers within the United States responded to the survey. Across all organs, acyclovir 400 mg twice daily was utilized by most respondents (70.4%) for a duration of 3 months (68.8%). No respondents reported use of famciclovir at their institution (Table 2).

Conclusions: Among our patients receiving the novel regimen of famciclovir 500mg once daily for CMV low risk antiviral prophylaxis, there were no documented cases of HSV/VZV/CMV infection while on prophylaxis. Nationwide, the most common antiviral prophylaxis used in CMV low risk SOT recipients is acyclovir 400 mg twice daily. Once daily famciclovir may provide an effective and convenient once daily dosing regimen for antiviral prophylaxis in CMV low risk SOT recipients.

Abstract# 781

Relationship Between Diabetes Mellitus and Covid-19 Prognosis in Kidney Transplant Patients

D. D. de Lucena, I. A. de Brito, M. P. Cristelli, J. O. Medina-Pestana, H. Tedesco-Silva, É. B. Rangel, *Department of Medicine, Division of Nephrology, Federal University of São Paulo, São Paulo, Brazil*

Purpose: A high number of comorbidities associated with the severity of the disease caused by SARS-CoV-2 (COVID-19) has been reported, such as systemic arterial hypertension (SAH), diabetes mellitus (DM), cerebrovascular and cardiovascular diseases, obesity, chronic kidney disease, among others. Importantly, poor glycemic control in diabetic individuals and hyperglycemia at admission are associated to COVID-19 progression. To evaluate whether kidney transplant recipients with DM have worse outcomes in COVID-19 setting when compared to non-diabetics, as well as to verify whether the poor glycemic control contributes to COVID-19 progression.

Methods: Retrospective analyses of 590 kidney transplant recipients who were diagnosed with COVID-19 at one single Brazilian center. We used DM, SAH and poor glycemic control as dependent variables in univariate analyses to determinant the risk factors for COVID-19 progression.

Results: 60% male, 64.4% white, average age 51.6 years-old, 192 (32.6%) DM and 158 (26.8%) SAH. COVID-19-related symptoms included: fever (63.4%), chills (63.4%), cough (60.3%), dyspnea (49.3%), myalgia (46.3 %), diarrhea (32.4%), anosmia (31.2%), headache (23.7%) and runny nose (21.7%). DM was associated with acute respiratory distress syndrome (ARDS) (P=0.0001), use of supplemental oxygen (P=0.001), intensive care unit (ICU) admission (P=0.0001), mechanical ventilation (MV) (P=0.001), acute graft dysfunction (P=0.0001), hemodialysis (P=0.009), and death (P=0.0001). Fasting blood glucose prior to hospitalization was related to the risk of death (130 vs 112 mg/dL, P=0.002), MV (130 vs 119 mg/dl, P=0.0001) and ICU admission (127 vs 109 mg/dl, P=0.0001). HbA1c values were associated with the risk of MV (7.2 vs 6.9%, P =0.031) and ICU admission (7.1 vs 6.6%, P=0.025). SAH was associated with ARDS (P=0.044), ICU admission (P=0.028), MV (P=0.018), graft dysfunction (P=0.006), HD (P=0.007) and death (P=0.037). ACE inhibitors or ARBs were not associated with the risk of death (P=0.792 and P=0.138, respectively).

Conclusions: DM and poor glycemic control, as well as SAH were associated with worse outcomes in COVID-19. These findings highlight the importance of adequate management of comorbidities in transplant patients, especially in relation to DM, since poor glycemic control contributes to the worst outcomes in COVID-19. ACE inhibitors and ARBs should not be discontinued during COVID-19 pandemic, as they do not increase the risk of death.

Abstract# 782

Management of Asymptomatic Bacteriuria in Kidney Transplant Recipients

A. Diamond, *Pharmacy, Temple University Hospital, Philadelphia, PA*

Purpose: Asymptomatic bacteriuria (ASB) is the presence of bacteriuria with no symptoms. Recent guidelines recommend against treatment of ASB in kidney transplant (KT) recipients more than 2 months post-transplant. These recommendations stem from clinical studies that have demonstrated minimal effect on graft function and low risk of progression to symptomatic urinary tract infection (UTI) if ASB is untreated. The risk of unnecessary antibiotic exposure may exceed the potential treatment benefits. The purpose of this study is to evaluate trends in treatment and clinical outcomes in KT recipients with ASB. In addition, current literature and guidelines only address urine culture growth of ≥ 10^5 CFU/mL and this study aimed to broaden that definition to include urine culture growth of ≥ 10^4 CFU/mL.

Methods: This was a retrospective chart review that included all patients 18 years and older with a KT at our institution between 1/20/2016 and 2/28/2019. Patients with multi-organ transplantation were excluded. The primary endpoint was the incidence of at least 1 episode of ASB between 2-12 months post-KT. ASB was defined based on two different yields of urine culture growth, ≥10^4 CFU/mL (noted as total ASB) and ≥10^5 CFU/mL (noted as guideline concordant (GC) ASB) with no symptoms. Secondary endpoints, evaluated for all ASB episodes, include treatment rate, progression rate to symptomatic UTI, ASB treatment agent and duration, and development of resistance (6 months from treated ASB). Graft function and patient survival were also assessed.

Results: 134 KT recipients were included. Incidence of at least 1 episode of ASB (per patient) for total and GC ASB was 29% and 16%, respectively. Treatment rates of total ASB and GC ASB cultures were 40% and 64%, respectively. Fluoroquinolones were the most common agents prescribed (61.7% of treated cultures). The median treatment duration of an ASB episode was 10 days. Progression rate of untreated ASB episodes to symptomatic UTI was 7.7% and for treated ASB episodes was 11.8% (P=0.71). Antibiotic resistance developed in 7.7% of treated cultures. Graft function was similar between the ASB population and the non-ASB population, with a median serum creatinine of 1.4 mg/dL for both groups at 12 months post-KT. Mortality was similar in both groups.

Conclusions: Overall, this study found that prescribers chose to treat 40% of ASB episodes, including cultures with less CFU/mL than the GC definition. With a low incidence of progression to symptomatic UTI identified and no difference in graft function, this study supports the guideline recommendations to routinely refrain from treatment of ASB episodes. Future studies are needed to further explore the association of treatment of ASB and development of antimicrobial resistance.

Abstract# 783

Survival Outcomes in Kidney Transplant Recipients Aged 18-60 Years by CMV Discordance Status: A Multivariable Analysis

A. Dinesh[1], T. Shaker[1], S. Jackson[2], S. Riad[3], T. L. Pruett[1], *[1]Division of Transplantation, Department of Surgery, University of Minnesota, Minneapolis, MN, [2]Biostatistics, Analytics Consulting Services- Solid Organ Transplant, M Health Fairview, Minneapolis, MN, [3]Department of Medicine, University of Minnesota, Minneapolis, MN*

Purpose: Despite advances in CMV therapeutics, CMV infection can pose significant comorbidity after transplantation. We sought to examine the impact of high-risk CMV discordance in our primary kidney transplant recipient population aged 18-60.

Methods: We retrospectively reviewed all primary kidney transplant recipients aged 18-60 years from 2008-2019. At our institution, we use Thymoglobulin (r-ATG) as induction with early steroid withdrawal followed by CNI plus MMF maintenance, and typically patients receive CMV prophylaxis with Valganciclovir for 90 days for low-risk (CMV IgG R+/D+, R+/D- or R-/D-) and 180 days for high-risk (CMV IgG R-/D+) status. We stratified our study population into clinically high-risk status recipients (CMV IgG R-/D+) (n=170) and low-risk status recipients (CMV IgG R+/D+, R+/D- or R-/D-) (n=652). Kaplan-Meier curves were generated for recipient survival, death-censored graft survival, and CMV-infection-free survival with follow-up censored at 5 years post-transplant. We examined the effect of CMV high-risk status on outcomes of interest in a multivariable Cox proportional hazards model adjusted for age, gender, race, BMI, maintenance immunosuppression, donor type, and donor age. CMV-free survival was not modeled due to severe proportional hazard violations.

Results: In univariate analysis, no difference was noted in patient survival (log-rank, p=0.465) or death-censored graft survival (log-rank, p=0.215) between low and high-risk groups. However, CMV-free survival was significantly lower in the high-risk group (log-rank, p<0.001). High-risk recipients had a 35% cumulative incidence of CMV infection at two years post-transplant, compared to 15% in the low-risk group. In the multivariable model, CMV status was not a predictor of patient survival (HR=0.71, 95% C.I. (0.26-1.90), p=0.50) or graft survival (HR=1.01, 95% C.I. (0.40-2.57), p=0.98).

Conclusions: In primary kidney transplant recipients aged 18-60 years, receiving r-ATG induction immunosuppression followed by CNI plus MMF maintenance with early steroid withdrawal, the incidence of post-transplant CMV viremia is significantly higher in high-risk CMV discordant recipients. However, it did not predict the patient or graft survival.

Abstract# 784

Does High-Risk CMV Discordance Affect Elderly Kidney Transplant Recipient Survival? A Multivariable Analysis

A. Dinesh[1], S. Jackson[2], S. Riad[3], T. L. Pruett[1], *[1]Division of Transplantation, Department of Surgery, University of Minnesota, Minneapolis, MN, [2]Biostatistics, Analytics Consulting Services- Solid Organ Transplant, M Health Fairview, Minneapolis, MN, [3]Department of Medicine, University of Minnesota, Minneapolis, MN*

Purpose: High-risk CMV discordance (R-/D+) has often been linked to deleterious outcomes after kidney transplantation. The elderly transplant population is more susceptible to CMV infections due to severe immunosenescence. We sought to examine the survival outcomes in our elderly kidney transplant recipients (≥60years) by CMV concordance status.

Methods: We retrospectively reviewed all primary kidney transplant recipients ≥60 years of age from 2008-2019. We use Thymoglobulin (r-ATG) as induction with early steroid withdrawal followed by CNI plus MMF maintenance, and typically, patients receive CMV prophylaxis with Valganciclovir for 90 days for low-risk (CMV IgG R+/D+, R+/D- or R-/D-) and 180 days for high-risk (CMV IgG R-/D+) status. We stratified our study population into clinically high-risk (CMV IgG R-/D+) (n=85) and low-risk status recipients (CMV IgG R+/D+, R+/D- or R-/D-) (n=376). Kaplan-Meier curves were generated for recipient survival, death-censored graft survival, and CMV-infection-free survival with follow-up censored at five years post-transplant. We examined the effect of CMV high-risk status on outcomes of interest in a multivariable Cox proportional hazards model adjusted for age, gender, race, BMI, maintenance immunosuppression, donor type, and donor age. CMV-free survival was not modeled due to severe proportional hazard violations.

Results: In univariate analysis, no difference was noted in patient survival (log-rank, p=0.372) or death-censored graft survival (log-rank, p=0.844) between low and high-risk groups. However, CMV-free survival was significantly lower in the high-risk group (log-rank, p<0.001). At two years from engraftment, the cumulative incidence of CMV infection was 42% of the high-risk recipients vs. 21% of the low-risk recipients. In the multivariable model, CMV status was not a predictor of patient survival (HR=1.10, 95% C.I. (0.54-2.23), p=0.80) or graft survival (HR=0.90, 95% C.I. (0.28-2.86), p=0.86).

Conclusions: In primary kidney transplant recipients ≥60 years of age, receiving r-ATG induction immunosuppression followed by CNI plus MMF maintenance with early steroid withdrawal, the incidence of post-transplant CMV viremia is significantly higher in the high-risk CMV discordant recipients. However, we did not detect an association between CMV discordance and patient or graft survival.

Abstract# 785

Outcomes of Kidney Transplantation at the Epicenter of the Covid-19 Pandemic: The Experience of the Ospedale Maggiore Policlinico

E. Favi[1], C. Alfieri[2], M. Gandolfo[2], A. Brescacin[1], M. Bilato[3], R. Cacciola[4], P. Messa[2], M. Ferraresso[5], *[1]Renal Transplantation, Ospedale Maggiore Policlinico, Milan, Italy, [2]Nephrology, Ospedale Maggiore Policlinico, Milan, Italy, [3]Urology, Ospedale Maggiore Policlinico, Milan, Italy, [4]HBP Surgery, Policlinico Tor Vergata, Rome, Italy, [5]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy*

Purpose: To evaluate patient- and allograft-related outcomes following living and deceased donor kidney transplantation (KTx) in a unit operating at the epicentrum of the COVID-19 pandemic.

Methods: Single-centre observational study comparing results of patients transplanted during the COVID-19 pandemic (SARS2-Tx group; 71#) with those remaining on the transplant waiting list (TWL) during the same period (SARS2-TWL group; 142#) or receiving a kidney in 2019 (CONTROL group; 75#) at the Ospedale Maggiore Policlinico, Milan, Italy. Data refer to latest follow-up available. Donor and recipient screening included: real-time reverse transcriptase polymerase chain reaction based molecular assay on nasal swab and BAL (at induction of anesthesia), serologic test, CRP, and chest high-resolution CT scan.

Results: Demographic and clinical characteristics of the three groups were similar with an equivalent proportion of high immunological and surgical risk subjects. Patient survival was 98.6% in SARS2-Tx, 96% in CONTROL, and 97.2% in SARS2-TWL (P=ns) whereas death-censored transplant survival was 97% in SARS2-Tx and 96% in CONTROL (P=ns). There were 3 episodes of COVID-19 infection in SARS2-Tx (4.2%; 2 asymptomatic and 1 with moderate respiratory symptoms), 6 in CONTROL (8%; 5 asymptomatic and 1 fatal), and 3 in SARS2-TWL (97.9%; all fatal). The vast majority of COVID-19 infections were acquired during transplant-related hospital stay or dialysis sessions. Rejection rates before and during the pandemic were comparable (6% vs 4.2%; P=ns) reflecting the fact that we did not change our immunosuppression strategy. In fact, median tacrolimus C0 as well as MMF and steroid daily doses in SARS2-Tx and CONTROL were not significantly different at any time point of the study.

Conclusions: Overall, our data seem to reassure centres worldwide willing to effectively continue their KTx program despite the COVID-19 crisis as no clinically relevant differences were observed among patients transplanted before and during the pandemic. The perceived increased risk of SARS-CoV-2 infection and virus-related death among patients remaining on dialysis further supports this point of view as long as strict and rigorous infection control strategies are embraced. A national multicentre study with larger population and longer follow-up is warranted to confirm these findings and help clinicians offer their patients adequate counselling.

Abstract# 786

Delay in Pediatric Kidney Transplantation Due to Infection: A Single Center Study

T. A. Heald-Sargent[1], S. Manz[2], P. Verghese[3], *[1]Pediatric Infectious Diseases, Lurie Children's Hospital/Northwestern University, Chicago, IL, [2]Central Michigan University, Mt Pleasant, MI, [3]Pediatric Kidney Diseases, Lurie Children's Hospital/Northwestern University, Chicago, IL*

Purpose: The infectious risks of immunosuppression following pediatric kidney transplant are well described but little is known about the impact of infections on patients with advanced chronic kidney disease awaiting kidney transplant. We hypothesized that infections were a common cause of delays in anticipated living donor transplants (LDKT) and accounted for increased periods of inactivation from the UNOS deceased donor (DDKT) waiting list.

Methods: We conducted a retrospective review of all pediatric kidney transplants completed at our institution between July 2015 and November 2020 to assess for infections as a cause of LDKT re-scheduling and / or inactivations on the UNOS waitlist. Patients that underwent multiple kidney transplants were included if both transplants were conducted at our center within the given time frame.

Results: A total of 86 pediatric kidney transplants (40% living donor) were performed at our institution (average age at transplant 11 years, range 1-20). Of the 4 (11%) LDKT that were delayed after an initial surgical date had been scheduled, two were due to active infections noted at the time of admission for transplant, one due to COVID-19 restrictions at the hospital, and one was not documented. In the 52 DDKT, 17 patients had 24 periods of inactivation from the UNOS waiting list that ranged in duration from 6 - 156 days (mean 27 days). Eleven (46%) of inactivation periods were due to infectious illnesses: 1 urinary tract infection, 1 disseminated varicella, 1 line infection, 3 peritonitis, 5 respiratory infections (two complicated with concurrent bacterial infections).

Conclusions: Infections during the pre-transplant period resulted in multiple delays of both living and deceased donor pediatric kidney transplants. Multicenter studies should be performed to assess the risk of infectious complications for children on the kidney transplant waiting list in order to evaluate risk mitigation strategies.

Abstract# 787

Clinical Outcomes and Management of Covid-19 Patients Among Kidney Transplant Recipients: A Systematic Review

S. Ismail[1], A. Babonj[2], S. Al Harbi[3], A. Babonj[2], A. Almalki[1], E. J. Murray[4], *[1]King Khalid hospital, MNGHA, Jeddah, Saudi Arabia, [2]King Abdulaziz University, Jeddah, Saudi Arabia, [3]King Faisal Specialist Hospital, Jeddah, Saudi Arabia, [4]Boston University School of Public Health, Boston, MA*

Purpose: We aim to systematically review published literature and synthesize the evidence available on therapeutic interventions and clinical outcomes used in the management of COVID-19 among adults' kidney transplant recipients (KTRs).

Methods: We searched PubMed, EMBase, the Cochrane registry for systematic reviews, and ClinicalTrials.gov with no language restrictions for articles published from November 1st, 2019 to August 13th, 2020 on adult KTRs diagnosed with COVID-19 infections in the inpatient and the outpatient settings. We excluded studies of other organ transplants or dual organ transplants. Two independent reviewers assessed articles for study selection and five researchers extracted data. Our primary outcome was to describe the use of therapeutics for the treatment of COVID-19, assess the alterations of the immunosuppressive regimens and the clinical progression of this patient group.

Results: We identified ninety eligible study (1052 KTRs), of which, 68 (155 KTRs) were case reports or cases series and 23 aggregate-level studies (897 KTRs) of descriptive observational data. Among the 155 patients described in case reports or case series, 44 received intravenous steroids while 55% continued their oral maintenance steroid doses. Aminoquinolines, azithromycin, antivirals, tocilizumab were used for 100, 64, 38, 24 KTRs respectively. Acute kidney injury (AKI) occurred in 56.6% , of whom 15 KTRs required renal replacement therapy (RRT). Twenty-five patients were admitted to intensive care units (ICU) and had a median ICU stay of 10 days,IQR (5-14). The median length of hospital stay was 17 days, IQR (11-29) and death occurred in 22.6% of patients. Antimetabolites were withheld or doses reduced in 90.9%. Among the 897 patients included in the aggregate-level studies, 26.5% died and 35.11% developed AKI, of whom 37 patients required RRT. The incidence of ICU admission in the aggregate-level data was 14.8%. Furthermore, Hydroxychloroquine, azithromycin and tocilizumab were used for 813, 491 and 373 KTRs respectively. Antimetabolites were stopped in 51.2%, calcineurin inhibitors were stopped or doses reduced in 320 KTRs, and 222 patients had an increase in their steroids' doses.

Conclusions: Kidney transplant recipients diagnosed with COVID-19 present a vulnerable population with high risk of severe clinical outcomes, including acute kidney injury, ICU admission, and mortality. A careful risk-benefit assessment between the use of antiviral drugs and the interruption of maintenance immunosuppressive agents including steroids is likely to be an important factor in the treatment of COVID-19 in this group.

Abstract# 788

Efficacy and Safety of a High Dose Ganciclovir Dosing Strategy in Kidney and Pancreas Transplant Recipients

M. Jorgenson[1], J. Descourouez[1], G. Leverson[2], C. Saddler[2], J. Smith[2], D. Mandelbrot[2], J. Odorico[2], *[1]UW Health, Madison, WI, [2]UW School of Medicine and Public Health, Madison, WI*

Purpose: Evaluate efficacy and safety of a strategy utilizing high dose ganciclovir in kidney and pancreas transplant recipients requiring hospital admission for CMV infection.

Methods: Adult kidney and pancreas transplant recipients admitted for CMV infection (4/29/19-7/15/20) received IV ganciclovir (10 mg/kg Q 12 hours x 7 days, renally adjusted) with step down to standard of care dosing thereafter (5 mg/kg Q12, renally adjusted). These patients were then compared to a standard of care (SOC) cohort admitted for CMV infection in a comparable time frame before implementation of the dosing strategy (10/20/16-3/2/19). Primary objective was response to the dosing strategy as measured by rate of viral clearance (delta log CMV) at day 7 of therapy. Secondary objectives were safety/toxicity as measured by leukopenia and short term (90 day) efficacy outcomes.

Results: 54 patients met inclusion criteria; 22 in the high dose cohort, 32 in the SOC cohort. Clinical characteristics were similar in the two groups, including induction type at transplant and degree of immunosuppressive modification in response to CMV diagnosis (Table). Patients who received the high-dose strategy had a significantly greater response to therapy at day 7 compared to the SOC cohort (high dose -0.92 log vs SOC -0.56 log, p=0.04). Change in WBC at day 7 was not different between groups (high-dose -0.49 vs SOC -0.45). Despite significantly more rapid clearance kinetics at day 7, the intensified dosing strategy was not associated with reduction in hospital length of stay (10.9 days high-dose vs 9.5 days SOC, p=0.52), 30 and 90 day all-cause readmission rates (30d: 4.5% high-dose vs 15.6% SOC, p=0.38, 90d: 13.6% high-dose vs 21.9% SOC, p=0.5) or clearance of viremia by day 90, as defined as achievement of CMV viral load less than lower limit of quantification (73% high-dose, 84% SOC, p=0.06).

Conclusions: A high dose strategy of IV GCV results in increased viral clearance kinetics without additional leukopenia at day 7 but does not significantly affect hospital length of stay, hospital readmission or viral clearance to <LLOQ at day 90. Future studies are needed to evaluate the effect of the rapid viral clearance kinetics induced by this strategy on outcomes of CMV infection, including persistence, resistance, recurrence as well as patient and graft survival.

Clinical characteristics

	High Dose (n=22)	Standard of Care (n=32)	P value
Age at Transplant	55.5 ± 12.3	54.4 ± 10.8	0.72
Male sex	12 (54.6%)	27 (84.4%)	0.03
Race Non-Hispanic White	19 (86.4 %)	26 (81.3%)	>0.99

Abstract# 789

Covid 19 Re-infection versus Re-activation in Two Renal Transplant Patients

L. Liriano-Ward, Y. Al Azzi, R. Bartash, C. Pynadath, M. Ajaimy, P. Loarte, J. Graham, S. Greenstein, M. Kinkhabwala, J. Rocca, E. Akalin, *Montefiore Medical Center, New York, NY*

Purpose: Rare cases of potential COVID 19 re-infection have been reported throughout the world.

Methods: We describe two renal transplant recipients with possible SARS-COV-2 re-infection.

Results: Patient #1 is a 63-year-old man with a history of renal transplant in February 2010, who initially experienced symptoms consistent with COVID-19 in April 2020 along with several family members. Due to limitations in outpatient testing, no SARS-CoV2 testing was able to be performed but he was treated as presumed COVID-19 infection due to high community prevalence and three weeks following his symptoms, SARS-CoV2 IgG was positive. The patient subsequently had four negative PCR tests from July-September 2020. In October, he was admitted for hypoxic respiratory failure and was found to be SARS-COV-2 positive by PCR and SARS-COV- IgG was negative (Figure 1). The patient was treated with Remdesivir and recovered. Patient #2 is a 64-year-old man with history of renal transplant in 2003, who was found to be SARS-COV-2 positive by RT-PCR in April 2020 after presenting with hypoxia. The patient had an uneventful hospital course and was discharged off supplemental oxygen. He had two negative SARS-COV-2 PCR tests in August and September and his SAR-COV-2 IgG was positive. In September, he was readmitted with hypoxic respiratory failure requiring intubation and ICU admission and was again found to be SARS-COV-2 positive by PCR. The patient had a complicated hospital course and expired on September 30th (Figure 1).

Conclusions: Potential cases of SARS-COV-2 re-infection have been previously reported, but it is unclear whether these are true re-infections versus reactivation of a prior infection, prolonged viral shedding, or dynamic RT-PCR results. In our cases, we believe prolonged viral shedding from the initial infection or inaccurate testing is less likely given the prolonged time interval between the two events, the multiple negative tests in between, and the severity of the second episodes. While both of these patients were suspected of having re-infections, this could not be confirmed as genomic analysis was not performed. Future studies of similar cases are needed to determine factors contributing to re-infection.

Abstract# 790

Infectious Complications and Malignancy After Kidney Transplantation in the Elderly Population

L. Liriano-Ward, M. Parides, Y. Al Azzi, C. Pynadath, M. Ajaimy, P. Loarte, J. Graham, S. Greenstein, M. Le, H. Yaffe, M. Kinkhabwala, J. Rocca, E. Akalin, *Montefiore Medical Center, New York, NY*

Purpose: All patients, regardless of age, may benefit from renal transplantation due to improved quality of life and decreased mortality. However, elderly patients are at an increase risk of developing side effects related to immunosuppressive medications including infections and malignancy. We aim to evaluate clinical outcomes in recipients older than 65 years of age.
Methods: This is a retrospective review of all patients over the age of 18 transplanted at our center from January 2013 to December 2018. We compared clinical outcomes including allograft and patient survival, as well as the development of infections (opportunistic and non-opportunistic) malignancy in patients older than 65 compared to younger patients.
Results: Of the 806 patients analyzed, 201 (24.9%) were older than 65 years of age. The two groups had no statistically significant difference in terms of gender and race. Older patients were more likely to receive a deceased donor kidney transplant (90% vs. 80.3%, p=0.002) and less likely to receive thymoglobulin induction (<0.001). During a median follow up of 46.6 months (28, 65), as expected mortality was higher in older patients (20.4% vs. 7.1%, p=0.0001), but compared to younger patients, there was no difference in terms of death-censored graft loss (10% vs 10.4 %, p=0.85). Detailed analysis of infections revealed that there was no difference in terms of BKV and CMV viremia, pneumonia, influenza and c. diff between the two groups. However, older patients had more fungal, urinary tract infections, and malignancy. 9% of elderly patients developed a fungal infection, the most common being PJP pneumonia (44%), followed by candida infection (39%), and cryptococcal infection (17%). 27% of elderly patients developed a malignancy, which included skin cancer (37%), prostate cancer (11%), breast cancer (7%), and colon cancer (7%), Kaposi's sarcoma (7%), among others occurring less frequently.
Conclusions: While recipients older than 65 had an increase incidence of fungal, urinary tract infections, and malignancies, their graft survival was similar to that of younger patients.

Clinical outcomes	Patients with age > 65	Patients with age <=65	p-value
BKV	16.4%	17.4%	0.43
CMV	11.7%	9.2%	0.31
Influenza	8.2%	9.9%	0.48
Pneumonia	23.1%	19.0%	0.22
C. Diff	7.2%	5.9%	0.51
Urinary tract inf	45.1%	29.7%	< 0.001
Fungal infections	9.7%	5.0%	0.02
Malignancy	12.8%	5.5%	< 0.001

Abstract# 791

Impact of Belatacept and Tacrolimus on Cmv Viral Load Control and Relapse in Moderate and High-risk Cmv Serostatus Kidney Transplant Recipients

W. Magua[1], A. C. Johnson[1], G. M. Karadkhele[1], I. R. Badell[1], P. Vasanth[1], M. G. Lyon III[2], A. K. Mehta[2], K. A. Easley[3], J. Rickert[4], C. P. Larsen[1], *[1]Department of Surgery, Emory University, Atlanta, GA, [2]Department of Medicine, Emory University, Atlanta, GA, [3]Biostatistics and Bioinformatics, Emory University, Atlanta, GA, [4]RStudio and R Consortium, San Jose, CA*

Purpose: We aim to evaluate the impact of belatacept and tacrolimus on CMV viral load control, remission and relapse in CMV high-risk (serostatus, D+/R-) and moderate-risk (D+/R+ or D-/R+) recipients.
Methods: We included 175 CMV recipients with at least 1 episode of viremia within 1 year after transplantation. We used a multi-state, continuous time homogenous Markov model to evaluate viral load transitions across states: state 1, undetectable or low viral load [0, 500) copies/mL; state 2, moderate viremia [500, 10^4) copies/mL; and state 3, high viremia (viral load >= 10^4).
Results: CMV high-risk belatacept-treated recipients presented an increased risk **(HR = 2.06; CI = 1.14, 3.74)** of transition from state 1 to 2 and a decreased risk **(HR = 0.365; CI = 0.164, 0.812)** of transitioning from state 2 to 3 than high-risk tacrolimus-treated recipients. Hence, state 2 emerged as a sticky state for high-risk belatacept-treated recipients. High-risk belatacept-treated recipients were predicted to persist in state 2 for a significantly longer time **(128 days, CI =110,145)** than high-risk tacrolimus-treated recipients **(70.6 days, CI = 47.6, 99.2).** Conversely, the high-risk tacrolimus group had greater persistence in state 1 compared to belatacept. In contrast, moderate-risk belatacept-treated recipients showed much better viral load control with a decreased risk of transitioning from state 2 to state 3 **(HR 0.307; CI =0.110, 0.852)** and with no other significant differences in viral load transition risks and in the short durations in viremic states when compared to moderate-risk tacrolimus-treated recipients.
Conclusions: High-risk belatacept-treated recipients showed a pattern of protracted viremia with impaired development of protective immunity. High-risk tacrolimus-treated recipients established some level of protective immunity despite blocking signaling in both naïve and memory T cells. Viral control was similar in moderate risk recipients treated with belatacept or tacrolimus. The results suggest that knowledge of viral-specific T cell response remains incomplete and that belatacept should be used with caution in CMV high-risk recipients while further strategies that can improve CMV serostatus matching are considered.

Abstract# 792

Impact of Non-active Hepatitis B on Patient Survival After Renal Transplantation

A. Paschereit[1], K. Budde[2], M. Duerr[2], M. G. Naik[2], *[1]Medical Department, Division of Nephrology and Internal Intensive Care Medicine, Charité University Medicine Berlin, Berlin, Germany, [2]Medical Department, Division of Nephrology and Internal Intensive Care Medicine, Charité, Berlin, Germany*

Purpose: Dialysis patients (pts) have an increased risk for hepatitis B (HB) infection and impaired response to HB vaccine compared to the general population. As shown in other studies, pts and graft survival in pts with chronic HB is worse. This study assesses the outcome of HBc-positive patients after kidney transplantation (KTx).

Methods: In our retrospective analysis we included all pts >18 years old, who underwent KTx from 01.01.1990 to 31.08.2019 in our center. Pts were grouped by their serostatus prior to KTx into "A: naïve" (HB negative), "B: HBc-positive" (non-active HB) and "C: HBsAg-positive" (chronic HB). Primary endpoints included pts and graft survival analyzed with Kaplan-Meier (KM) and log-rank test. Regression analysis (RA) was applied to determine independent risk factors for the occurrence of primary endpoints.

Results: Out of 2487 KTx pts we identified n=2198 HB naïve, n=218 non-active HB and n=75 chronic HB pts. Overall 29.1% (A:27.7%, B:37.6%, C:45.3%) pts died and 20.3% (A:19.1%, B:27.5%, C:37.3%) pts suffered from graft failure. 5-year pts survival was A: 87.0%, B: 82.8%, C: 82.2%. 10-year pts survival was A: 71.7%, B: 61.1%, C: 64.5% and 20-year pts survival was A: 43.1%, B: 26.1%, C: 40.9% (p=0.01). Pts and graft survival rate (fig. 1) was: 5 year A: 78,7%, B: 74,2%, C: 68,6%, 10 year A: 59.8%, B: 46.4%, C: 51.8%, 20 year A: 30.8%, B: 26.4%, C: 14.9% (p=<0.001). RA (fig. 2) showed that anti-HBs positivity (≥100 IE/l) was a protective factor for graft failure and death (p<0.001).

Conclusions: HB leads to earlier graft loss and inferior pts survival. Beside the known negative effect of chronic HB, also in pts with non-active HB infection overall survival was significant worse to HB naïve pts. Thus, non-active HB is an important risk factor for transplant outcome. Next, influence of antiviral and immunosuppressive regimens and incidence of HB-reactivation are to be analyzed.

Abstract# 793

Intensive Monitoring and Early Treatment for Urinary Infection in Renal Transplant Recipients Reduces Readmission and Sepsis

A. Patel, S. Desai, B. R. Schleich, M. Wynd, T. Carrea, Y. Yushkov, S. Geatrakas, N. White, R. Luongo, R. Sosnicki, V. Wadhera, D. Serur, M. J. Goldstein, *Organ Transplant, Hackensack University Medical Center, Hackensack, NJ*

Purpose: Urinary tract infection (UTI) is a common renal transplant (RT) complication that is observed in up to 60-70% of RT recipients and may affect allograft function and long-term survival. A retrospective review identified an opportunity for reduction in the adverse events related to post-RT UTI. We hypothesized that implementation of an early detection and treatment program would reduce the incidence of readmission and complications from UTI after RT.

Methods: An intensive, prospective UTI monitoring and treatment performance improvement plan (PIP) was established in April 2018. A retrospective cohort study was conducted comparing patient outcomes after PIP with cases before implementation. We defined bacteriuria as having 25,000 to 100,000 and UTI having more than 100,000 bacteria present on urine culture. Urinalysis and urine culture were sent on all RT recipients weekly for 1-month post-RT Recipients at higher risk (recurrent history of UTI before RT, urinary retention history and congenital or acquired urogenital abnormalities) for UTI were monitored for 3 months.

All symptomatic patients within 3 months and all asymptomatic patients within 1 month of RT with bacteriuria on uncontaminated urinalysis were treated empirically. High risk, asymptomatic patients within 3 months of RT with bacteriuria on uncontaminated urinalysis were treated empirically.

Results: A retrospective data analysis comparing RT case controls (N=73) and post PIP implementation (N=220) was conducted. Figure 1 shows that the prevalence of urine testing was much higher post protocol implementation. Despite a higher 3-month UTI rate most likely detected through more screening, post-RT outcomes were significantly (p<0.05) improved after PIP implementation for 90-day readmissions with UTI, diagnosis of sepsis, and rejection (Figure 2).

Conclusions: The 11% UTI rate observed within 3 months resulting from this PIP is one among the lowest observed. The reported high incidence of UTI and adverse outcomes related to this complication can be mitigated through intensive monitoring, detection, and a lower threshold for early treatment. While protocol testing identified a slightly higher incidence of UTI relative to case controls, as expected, there was a significant reduction in the severity of disease requiring a readmission for UTI or sepsis. We did not identify adverse effects of early antibiotic intervention for symptomatic or asymptomatic bacteriuria.

Abstract# 794

Unquantified Blips Lead to CMV Slips - Post Transplant CMV Monitoring in High Risk Kidney Transplant Recipients

A. T. Payne[1], J. G. Timpone[2], A. Gilbert[2], B. Thomas[2], B. K. Lindner[2], *[1]Georgetown University School of Medicine, Washington, DC, [2]Medstar Georgetown University Hospital, Washington, DC*

Purpose: Cytomegalovirus (CMV) is a significant cause of morbidity, mortality, and graft failure after solid organ transplantation, with high risk (D+/R-) patients being the highest risk for infection. While guidelines suggest using highly sensitive, quantitative NAT (QNAT) assays for CMV detection, they stipulate "there is no widely applicable viral load threshold to guide preemptive therapy". This study evaluates the progression to CMV viremia following a CMV "blip" in high risk kidney/kidney-pancreas (KP) transplant recipients.

Methods: This is a single center, retrospective study of CMV high risk kidney or KP transplant recipients from January 2015 - April 2020. A CMV "blip" was defined as a first positive QNAT assay below the level of quantification (< 1.37 x 10^2 IU/mL). Subsequent CMV QNAT assays were followed to assess the progression from blip to CMV viremia, syndrome, or tissue invasive disease. Outcomes were assessed for 1 year from the date of transplant and were evaluated using descriptive statistics and the chi-squared test.

Results: One hundred thirty-four patients were included in the study. Fifty-three (39.6%) patients had their first positive CMV QNAT value below the level of quantification and were considered a CMV "blip". Of these 53 patients, 69.8% (n=37) progressed to viremia while 30.2% (n=16) did not. The median time from transplant to the first CMV blip was 68 (46-97) days and the majority of blip patients (71.1%) were receiving anti-viral prophylaxis at the time of their blip. Median time from blip to CMV viremia was 19.5 (7-28) days. Low rates of CMV syndrome (7.5%) and resistant CMV (1.9%) were found in the blip population (n=53) or the overall population (n=134), 5.2% and 0.75% respectively. No differences were found when comparing patients who progressed from blip to viremia to those who only had a blip.

Conclusions: In CMV high risk kidney/KP transplant recipients, CMV blips progressed to CMV viremia in the majority of cases. This progression typically occurred 2-3 weeks following the initial blip. Early CMV treatment or the development of monitoring protocols after blip identification could prevent the progression to CMV viremia or syndrome.

Abstract# 795

Discontinuation of Trimethoprim/sulfamethoxazole Prophylaxis Due to Hyperkalemia in Kidney Transplant Recipients

D. Pett[1], G. Malat[2], C. Domenico[1], R. Samudralwar[1], A. Forte[1], D. Sawinski[2], J. Hu[1], B. Steiner[1], J. Rashid[1], J. Trofe-Clark[2], *[1]Pharmacy, Hospital of Univ of Pennsylvania, Philadelphia, PA, [2]Penn Transplant Institute, Hospital of Univ of Pennsylvania, Philadelphia, PA*

Purpose: Trimethoprim-sulfamethoxazole (TMP-SMX) is the drug of choice for Pneumocystis jirovecii pneumonia (PJP) prophylaxis in kidney transplant recipients (KTRs), however, it can be complicated by hyperkalemia. Study aims were to assess the number of KTRs who discontinued TMP-SMX as an intervention for hyperkalemia within 6 months (mos) post-op vs those who did not, and to describe risk factors for hyperkalemia in both groups.

Methods: This IRB approved single-center retrospective case-control analysis included KTRs who were: ≥ 18 yrs, HIV negative, transplanted at our center Jan 2019-Jan 2020, initiated on tacrolimus (TAC) immunosuppression and TMP-SMX PJP prophylaxis at transplant, and had ≥ 6 mos follow-up. Hyperkalemia (defined as ≥ 2 consecutive serum potassium levels ≥ 5 mEq/L) was assessed at defined time-points: 1 week (wk), 2 wks and monthly for 6 mos post-op.

Results: This interim analysis included 100 of 200 KTRs. Overall, the majority of KTRs were male (60%), Caucasian (55%) and were deceased donor KTRs (58%). Glomerulonephritis was the primary cause of kidney failure in 27% of KTRs. TMP-SMX was discontinued in 23 KTR and held in 2 KTR (25% overall) within 6 mos post-op. Hyperkalemia was the reason for holding/discontinuing TMP-SMX in 8% of KTRs. The overall hyperkalemia incidence was 38%. Evaluated time-point where hyperkalemia was most commonly first experienced was 2 wks post-op (40% of KTRs). When comparing earlier vs later evaluated time-points, hyperkalemia occurred more frequently early on [(87%) KTRs with hyperkalemia first identified at 1 wk-2 mos vs 3-6 mos (13%), p =0.001]. A significant risk factor for hyperkalemia was pre-existing diabetes mellitus (DM) with an additional numeric trend for post-transplant DM (Table 1). There were no differences in delayed graft function (DGF) or low eGFR at wk 2 between groups (Table 1), or at other timepoints (data not shown). One yr graft loss occurred in 5 KTRs (5%) with death being the cause in 1 KTR.

Conclusions: 1) TMP-SMX, considered first-line PJP prophylaxis, was held/discontinued in a quarter of KTRs overall, with hyperkalemia being the reason in < 10% of KTRs. 2) Hyperkalemia occurred in almost 40% of KTRs, and most commonly occurred in the first 2 wks post-op. 3) A significant risk factor for hyperkalemia was pre-existing DM with a numeric trend for post-transplant DM. Data collection is ongoing, and will include data on use of potassium lowering therapies.

Risk Factors for Acute Hyperkalemia in KTRs			
Parameter Evaluated	Hyperkalemia Identified (n=38) n (%)	No Hyperkalemia Identified (n=62) n (%)	p Value
Age ≥ 60 yrs	13 (34%)	16 (26%)	0.5016
Pre-transplant DM	16 (42%)	9 (15%)	**0.0039**
Deceased donor kidney	27 (71%)	31 (50%)	0.0626
Occurrence of DGF	9 (24%)	9 (15%)	0.3734
Supra-therapeutic TAC at wk 2 (>12 ug/L)	8 (21%)	22 (36%)	0.0905
eGFR <30 ml/min/1.73 m^2 at wk 2	3 (8%)	7 (11%)	0.8368
Post-transplant DM	5 (13%)	20 (32%)	0.0570

Abstract# 796

Covid Infection Among Kidney Transplant Recipients: Management and Outcomes

A. Price, K. Soliman, C. Zayas, V. Rao, M. Casey, D. Taber, M. Posadas Salas, *Medical University of South Carolina, Charleston, SC*

Purpose: COVID pandemic has posed a significant challenge among kidney transplant recipients (KTR) due to their immunocompromised state. There is uncertainty on immunosuppression management among those who have COVID infection. We sought to better understand the clinical course, management, and outcomes of our KTR who developed COVID infection.

Methods: Single-center experience of COVID infected KTR. Baseline demographics, clinical data, management, and outcomes were obtained by manual chart abstraction of the EMR.

Results: 50 KTR had COVID infection. Mean age was 53; 50% males; 74% African-Americans. Fever was the most common symptom (71%); 36 patients (71%) required hospitalization; 11 (22%) required ICU admission and 8 (16%) required mechanical ventilation. 23 developed AKI with one-third requiring RRT; 50% of patients requiring RRT eventually had renal recovery. Majority of admitted patients received dexamethasone, remdesivir, and convalescent plasma. In terms of immunosuppression, 28 of 49 (57%) had their MMF held while 8% had MMF dose reductions; one had everolimus held and one had AZA held; 7 (14%) had CNI dose reductions with none held. Six patients (12%) died. Those who died were significantly more likely to receive dexamethasone (42% vs 2%; p=0.002), remdesivir (33% vs 7%; p=0.027), and convalescent plasma (40% vs 0%; p=0.001). Mortality rates were similar across those who had immunosuppressive agents dose reduced vs held vs not adjusted (11% vs 17% vs 12%, respectively; p=0.919). CNI dose reductions tended to be more common in those who died (43% vs 7%; p=0.122). There were no subsequent acute rejections or graft losses in those who recovered.

Conclusions: KTR represent a vulnerable patient population during COVID. Due to their immunocompromised state and often more severe clinical presentation, the majority require hospitalization, with a significant number needing ICU admission and mechanical ventilation. Severe illness led to higher use of dexamethasone, remdesivir and covalescent plasma in those who ultimately died of COVID. It is unclear what impact immunosuppression dose reductions had on the COVID clinical course, but these reductions did not appear to increase risk of rejection or graft loss.

Table 1. Clinical Parameters

Parameters	
Total number of COVID episodes	N=51
Onset of COVID infection	
<3 months post-transplant	6 (12%)
3-12 months post-transplant	7 (14%)
1-3 years post-transplant	14 (27%)
>3 years post-transplant	24 (47%)
Symptoms	
fever	36 (71%)
respiratory	33 (65%)
GI	13 (25%)
asymptomatic	2 (4%)
Required hospitalization	36 (71%)
Mean length of hospital stay (days)	12
Length of hospital stay	
≤3 days	11 (30.5%)
4-6 days	11 (30.5%)
≥7 days	14 (39%)
Required ICU admission	11/36 (30.5%)
Required O2 support	16/36 (44%)
Required mechanical ventilation	8/36 (22%)
Required ECMO	1/36 (3%)
Developed AKI	23/51 (45%)
Managed outpatient	1/23
Managed inpatient but no RRT	15/23
Managed inpatient with RRT	7/23
AKI resolved	20/23(87%)
Renal recovery in those who required RRT	3/7 (43%)
Death	6 (12%)

Table 2. Management of COVID infection

Management	Number of patients
Dexamethasone	12
Remdesivir	9
Convalescent plasma	15
Reduced MMF dose	4
Held MMF	28
Reduced CNI dose	7
Other immunosuppression reduction	4

Abstract# 797

SARS-CoV-2 Infection Among Kidney Transplant Recipients: A Multicenter Brazilian Cohort Study

T. Sandes-Freitas[1], J. Medina-Pestana[2], o. COVID-19 Brazil Study Group[3], *[1]Universidade Federal do Ceará, Fortaleza, Brazil, [2]Hospital do Rim, São Paulo, Brazil, [3]Brazil, Brazil, Brazil*

Purpose: Limited data are available on COVID-19 clinical presentation and outcomes among kidney transplant (KT) recipients.

Methods: Multicenter Brazilian cohort of KT patients with laboratory-confirmed SARS-CoV-2 infection. Patients were followed for 3 months. In this preliminary report, we included patients added to the database until 19thSep20 (40 centers, 1,145 patients).

Results: 68% received deceased donor grafts, 60% were male, the median age was 52 years (IQR 42-60), median time post-KT was 5.7 years (IQR 2.1-11.1), and 94% had comorbidities beyond chronic kidney disease. 12.6% had nosocomial-acquired COVID-19, the main signs/symptoms were fever (64%), cough (51%), dyspnea (36%), myalgia (33%), and diarrhea (29%). Main laboratory abnormalities were lymphopenia (756 cells/mm^3, IQR 446-1164), increased C-reactive protein (18.9 mg/dl, IQR 5.5-70.7), and acute kidney injury (AKI) (48%). Ground-glass opacities were the main radiological finding (55%). 68% of patients required hospitalization, 35% intensive care, 28% mechanical ventilation (MV), 26% require dialysis, 9% lost their grafts, and 24% died. Lethality rates were 36% and 82%, respectively, among hospitalized patients and among those who needed MV. Age (years)(HR 1.059), BMI (Kg/m^2)(HR 1.052), baseline creatinine (mg/dL)(HR 1.425), delta creatinine (mg/dL) (HR 1.385) and lactic dehydrogenase (LDH)(U/L)(HR 1.001) were risk factors for death.

Conclusions: Except for the higher incidence of diarrhea, lymphopenia, and AKI, clinical presentation appeared to be similar to that described for immunocompetent patients. A high percentage of patients in this cohort required hospitalization, probably because patients who sought medical care were those with more severe disease. The lethality rate was high and similar to that described in international cohorts. Older patients, obese, those with inferior baseline renal function, and graft dysfunction were at higher death risk. Higher LDH was also associated with death risk, possibly reflecting larger pulmonary injury.

Abstract# 798

Risk Factors Associated with Multidrug Resistant Organism (MDRO) Infections in Kidney Transplant Recipients: A Single Center Experience

S. Schrank[1], J. Timpone[2], B. Javaid[3], P. Kumar[2], M. Cooper[3], *[1]Internal Medicine, MedStar Georgetown University Hospital, Washington, DC, [2]Infectious Diseases and Travel Medicine, MedStar Georgetown University Hospital, Washington, DC, [3]Transplant Institute, MedStar Georgetown University Hospital, Washington, DC*

Purpose: Risk factors for MDRO infections in kidney transplant recipients have previously been studied but limited to urinary tract infections. We sought to evaluate the rate and risk factors of all MDRO site infections.

Methods: A retrospective chart review was performed on kidney transplant recipients from 2018 to 2019 at our transplant center. Recipients were followed for 1 year post transplantation to evaluate for infection. Demographic and clinical data were abstracted from the EMR. Analysis was completed using Fisher's exact test, Student's t-test, and descriptive statistics.

Results: 300 transplant recipients were evaluated, 182/300(60.7%) were male and 118/300(39.3%) female. Mean age at transplant was 53 years. 163/300(54.3%) received a deceased donor kidney and 137/300(45.7%) received a living donor kidney. 64/300(21.3%) experienced delayed graft function, 51/300(17%) required hemodialysis post-transplant, and 13/300(4.3%) required treatment for rejection. The average duration of ureteral stents was 35.5 days. 128/300(42.7%) required readmission to the hospital. 72/300(24%) patients were treated for a total of 151 bacterial infections which included: complicated UTI/pyelonephritis 116/151(78.8%), blood stream 19/151(12.5%), intraabdominal 6/151(3.9%), gastrointestinal 5/151(3.3%), skin and soft tissue/surgical site 3/151(2.0%), and respiratory 2/151(1.3%). *C. Difficile* infection occurred in 5/300(1.7%). 5/300(1.7%) had laboratory confirmed MDRO infections. Of patients with documented infections, 5/72(6.9%) were MDRO, which included 3 gram-negatives (2 Enterobacteriaceae ESBLs, 1 MDR *Pseudomonas Aeruginosa*) and 2 gram-positives (1 VRE, 1 MRSA). No infections due to CRE Enterobacteriaceae were observed. Significant differences in patients with treated MDRO infections compared to those without are as follows; post-operative hemodialysis (60% vs 20.4%; p=0.04) and length of stay postoperatively (11.0 vs. 5.03 days; p=0.0003). There were no significant differences found between those with MDRO infections compared to those without for the following; average HbA1c(5.3 vs. 6.2; p=0.33), age(46.4 vs. 53.7; p=0.21), sex(male 1.6% vs. female 1.7%; p=1.0), delayed graft function(3.0% vs. 1.3%; p=0.29), mean duration of stents(27.6 vs. 35.6 days; p=0.1), and type donor (deceased 1.8% vs. living 1.5%; p=1.0).

Conclusions: We observed a low prevalence of MDRO infections in our kidney transplant population. MDRO infections were associated with post-transplant hemodialysis and post-transplant length of stay.

Abstract# 799

Predictive Factors and Management of Urinary Tract Infections After Kidney Transplantation: A Retrospective Cohort Study

T. Shimizu, Y. Kinoshita, T. Shinzato, D. Iwami, *Jichi Medical University, Shimotsuke City, Japan*

Purpose: Urinary tract infection (UTI) is one of the most common infectious complications in kidney transplant recipients. The predictive factors for UTI are controversial because of wide discrepancies in the frequency and causes of the development of posttransplant UTI. We investigate the factors that can predict the development of UTI and the type of pathogenic bacteria isolated from kidney transplant recipients to elucidate the predictive factors of UTI development, and we advocate for the proper management of posttransplant patients.

Methods: This study was a single-center retrospective cohort study of kidney transplant recipients (≥18 years old) who underwent KT from January 2013 to December 2018 at Jichi Medical University Hospital. Kidney transplant recipients were divided into two groups: UTI group and no UTI group. The primary outcome measure of this study was the incidence of UTI. UTI was defined as the detection of pathogenic bacteria in urinary culture tests and various relevant symptoms in patients. A P-value <0.05 was considered to be statistically significant.

Results: A total of 163 kidney transplant recipients were eligible during the study period and included in the analysis. Forty-one patients (25.2%) were assigned to UTI group, and 122 patients (74.8%) were assigned to no UTI group. Cox hazard regression analysis after variable selection using the stepwise method was performed for the characteristics that were significant in the univariate analysis, and urinary catheterization and small bladder capacity (<150mL) in addition to serum albumin levels at one month after KT were independent predictive factors for UTI onset. The number of patients developing their first UTI was 15 (36.6%) within one month and 24 (58.6%) within one year after KT, respectively. The median period to UTI onset (UTI-free survival) after KT was 189 days (Figure). UTI-free survival was defined as the duration from KT until the occurrence of a UTI. Urine culture led to the identification of a total of 83 UTI-related organisms, including multiple organisms in 15 patients. The microorganism most commonly identified was *Escherichia coli* (n=47), followed by *Enterococcus* spp. (n=13), and *Klebsiella* spp. (n=10).

Conclusions: Kidney transplant recipients with prolonged postoperative malnutrition, posttransplant voiding dysfunction and/or urinary storage disorder had an increased risk of UTI. Bladder function tests were needed to predict UTI. Kidney transplant recipients who develop UTI should be treated as complicated UTI patients.

Figure. Time to first UTI onset (UTI-free survival) after KT in the UTI group

Abstract# 800

An Unusual Viral Tropism in a Solid Organ Transplant Recipient

P. Singh, A. Bentall, C. Langstraat, A. Swanson, P. Deziel, Y. Huang, R. Razonable, *Mayo Clinic, Rochester, MN*

Purpose: Cytomegalovirus (CMV) tissue-invasive disease occurs in higher proportion in CMV-mismatched kidney transplant recipients (KTxR) with no pre-existing immunity and those who are markedly immunologically-impaired. While CMV disease may affect any organ, cervicitis has not been reported in KTxR.

Methods: A 46 year old woman with end stage kidney disease due to adult polycystic kidney disease underwent a living unrelated donor kidney transplant. She received induction with thymoglobulin and was maintained on belatacept, mycophenolate mofetil (MMF) and prednisone. She was a CMV mismatch and was receiving Valganciclovir 900 mg daily prophylaxis. Patient also had a history of cryotherapy for abnormal Pap smear and endometrial ablation for abnormal uterine bleeding. Post-transplant, she developed antibody mediated rejection which was treated with plasmapheresis, intravenous immunoglobulins and eculuzimab. Eight weeks later, she developed acute cellular rejection and received thymoglobulin and methylprednisone. Serum creatinine settled down at 1.5 mg/dl. Four months post-transplant, she developed watery diarrhea while still being on valgancilovir. CMV DNA level was 123,000 IU/ml plasma. She was switched to IV ganciclovir while MMF was discontinued, and prednisone increased to 10 mg along with CytoGam infusions. CMV titers increased to up to 2 million copies and treatment was changed to IV Foscarnet because of CMV UL97 resistance confirmed by next generation sequencing.
Results: Surveillance ultrasound (US) of kidney revealed a right adnexal cyst which led to transvaginal US showing increased endometrial fluid collection. Dilation and curettage failed thus leading to an MRI of pelvis which showed multilocular cysts within cervix (Figure 1) suspicious for *adenoma malignum*. As such, a cervical biopsy was performed which showed viral inclusions consistent with CMV infection (Figure 2). These CMV-induced changes were confirmed on immunohistochemistry.
Conclusions: CMV occurs commonly in the most immunocompromised KTxR and may be manifested in atypical syndromes. Our case shows the first description of CMV cervicitis in a KTxR. The presence of an endocervical mass during episodes of CMV viremia should prompt a consideration of CMV disease of cervix.

Abstract# 801

Incidence of Oral Candidiasis in Renal and/or Pancreas Transplant Recipients When Administering Prophylaxis versus No Prophylaxis

L. Von Stein[1], S. Patel[1], L. Wardlow[2], *[1]Transplant, The Ohio State Wexner Medical Center, Columbus, OH, [2]Pharmacy, The Ohio State Wexner Medical Center, Columbus, OH*

Purpose: Oropharyngeal candidiasis (OC), or thrush, is a fungal infection associated with immunosuppression post renal and or/pancreas transplant. Currently, the role of prophylactic oral nystatin for OC is controversial as incidence is variable. This study compares the incidence of OC within 3 months post renal and/or pancreas transplant in patients receiving 0, 1, or 3 months of oral nystatin.
Methods: This study was a retrospective analysis of patients who underwent kidney and/or pancreas transplant between August 2018 and March 2020. Exclusion criteria included: alternative antifungal agent used for prophylaxis (ie: clotrimazole, fluconazole), the use of antifungal therapy for indication other than OC, and death within 3 months post-transplant. The primary outcome compared incidence of OC development after receiving no prophylaxis, 1 month, or 3 months of nystatin prophylaxis. Secondary outcomes include time to OC, severity of OC and readmission rates due to OC.
Results: A total of 238 patients met inclusion criteria, 68 received no nystatin prophylaxis, 87 received 3 months of prophylaxis, and 83 received 1 month of prophylaxis (Table 1). Baseline characteristics were similar between groups with the majority of patients receiving ATG induction and tacrolimus with mycophenolate sodium for maintenance immunosuppression. There was a greater incidence of OC in the no prophylaxis group compared to 1 month and 3 months of prophylaxis (5.9% vs 0% vs 0%). Three out of four patients developed OC within 30 days post-transplant. Patient 2 was readmitted for OC, while Patient 3's index admission was extended due to OC (Table 2). Of the patients being treated for OC, none worsened to esophagitis.
Conclusions: Given the low incidence of OC infections post-transplant and concern for patient adherence, a shortened duration of 1 month of nystatin prophylaxis is reasonable to decrease the occurrence of OC. Given the small sample size, further evaluation of 1 month OC prophylaxis versus no prophylaxis should be considered.

Table 1. Baseline Demographics and Clinical Characteristics

Abstract# 802

Clinical and Pathological Features of Lobar Nephronia in Renal Allograft

Y. Wang[1], Z. Yan[1], Y. Liu[1], Y. Zhou[1], Y. He[1], W. Zeng[1], R. Xia[1], W. Deng[1], J. Xu[1], C. Wu[2], Y. Miao[1], *[1]Department of Organ Transplantation, Nanfang Hospital, Southern Medical University, Guangzhou, China, [2]Department of Urology and Pathology, Massachusetts General Hospital, Harvard Medical School, Boston, MA*

Purpose: Lobar nephronia (acute focal nephritis) is a rare form of nephritis which can be presented as a renal mass and misdiagnosed as renal cancer, resulting in nephrectomy. Several single case reports of this disease in renal allograft have been published. The aim of this study is to characterize the clinicopathological features of lobar nephronia in renal allograft.
Methods: Seven recipients were diagnosed with lobar nephronia in renal allografts in our hospital. The disease presentation, including clinical manifestations, imaging studies, pathological and lab data, are summarized and analyzed.
Results: The disease presentation can be divided into three phases (Table 1). Phase I: Early Urinary tract infection (UTI). Mild urinating discomfort or white blood cells in urine are found. Phase II: Acute pyogenic infection. Typical symptoms of acute pyelonephritis including hyperpyrexia, chills, discomfort in the allograft area and significant infectious index. Regional renal parenchyma is extensively involved by the inflammatory process, leading to a mass formation. Imaging investigations indicate renal enlargement with exudation. PET-CT displays consolidation and hypermetabolic foci which can be easily misdiagnosed as malignancy. Biopsy can

be performed to establish the diagnosis and exclude malignancy. Phase III: Chronic scarring after infection. Clinical symptoms ameliorate promptly after administration of antibiotics; however the renal lesions will not disappear simultaneously. Inflammation will reduce and result in fibrosis and scar. Eventually PET-CT will not detect focal lesion. (Figure 1)

Conclusions: Sufficient antibiotics and regular follow-up are of great importance for recipients with UTI after transplantation. Besides, it's crucial to distinguish lobar nephronia from malignancy and post-transplant lymphoproliferative disorders.

Table 1. Disease presentation at the patient cohort.

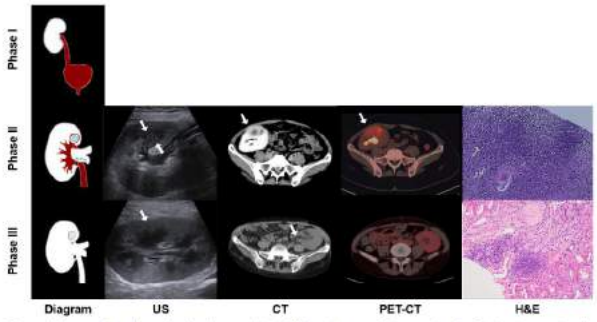

Figure 1. Diagram, imaging and pathology results at different stages of lobar nephronia. Dark red areas show the range of inflammation. Blue particles represent pathogens. Light capsules with obvious rim represent consolidations. Phase I: Early urinary tract infection. There is no abnormal imaging and pathological findings. Phase II: Acute pyogenic infection. Ultrasonography (US) shows heterogeneous liquid anechoic area mostly at the upper pole of renal parenchyma with unclear borders, while some lesions turn into solid mass. Computed Tomography (CT) reveals heterogeneous hypodense mass in renal allograft with ill-defined margins, and enhanced scanning shows moderate enhancement. PET-CT displays solid lesion and hypermetabolic foci. Pathological biopsy is beneficial to confirm the diagnosis, which presents suppurative lesions and proliferation of surrounding fibrous tissue without signs of oncogenesis and rejection. Phase III: Chronic scarring after infection. US shows increased echogenicity with inner heterogeneous hypoechoic area and ill-defined margins. CT reveals the increasing density of adipose space. There is no apparent abnormality in PET-CT images. Hematoxylin and Eosin (H&E) staining demonstrates chronic tubulointerstitial injury and fibrosis.

Real-world Treatment Patterns of Antiviral Agents for Cytomegalovirus Among Adult Kidney Transplant Recipients: A USRDS-Medicare Linked Database Study

A. D. Raval[1], M. Ganz[2], P. Saravanan[2], Y. Tang[1], C. A. Santos[3], *[1]Merck & Co., Inc., Kenilworth, NJ, [2]Evidera, Inc., Waltham, MA, [3]Rush University Medical Center, Chicago, IL*

Purpose: Cytomegalovirus (CMV) is a common viral pathogen among kidney transplant recipients (KTRs). Although guidelines recommend the use of prophylaxis or pre-emptive antiviral (AV) therapy depending on the risk level, limited data exist on the recent national level treatment patterns of CMV antiviral agents (AV) among KTRs. We examined the real-world CMV-AV utilization patterns among adults KTRs in the United States (US) overall and by CMV serostatus of donor (D) and recipients (R).

Methods: We utilized a retrospective cohort design using the US Renal Data System registry-linked Medicare data from January 1, 2011, through December 31, 2017. The study cohort included adults undergoing their first KT during the study period with continuous medical coverage for at least 6-month pre and 12-month post KT and pharmacy benefits coverage for at least 12-month post- KT. CMV-AV prophylaxis was defined as ≥ 1 prescription fill or medical claim for either (val)acyclovir or (val)ganciclovir (VGC) therapeutic dose within 28 days post-KT. Descriptive statistics were reported by CMV prophylaxis status by CMV risk strata (low: D-/R-; medium: R+; and high: D+/R).

Results: The study cohort comprised of 23,445 KTRs of which 11%, 74% and 15% were at low, medium and high risk of CMV, respectively. The mean age (standard deviation, SD) of KTRs was 53.8 (13.9) years. The majority of KTRs were males (59%), Whites (59%) and African Americans (33%); received a graft from deceased donor (86%); and received induction with anti-thymocyte globulin (54%), mycophenolate (96%), tacrolimus (95%), and steroids (96%). CMV-AV prophylaxis was used by 35%, 83%, and 85% of low-, intermediate- and high-risk KTRs, respectively. Overall, valganciclovir was utilized in 98% of KTRs treated with CMV AV-prophylaxis. From 2011 to 2016, an increase in the use of VGC 900 mg in high-risk and a relatively stable trend of VGC 450 mg dose were noted in intermediate-risk KTRs. The mean duration of CMV prophylaxis was 102 (SD:70.4) days. Proportions of KTRs with duration of CMV prophylaxis ≥100 and ≥ 200 days were 50% and 11% of high-risk, and 25% and 5% of intermediate-risk KTRs, respectively.

Conclusions: Valganciclovir was commonly utilized as CMV-AV prophylaxis. The majority of KTRs had shorter than the guideline-recommended duration of 100 or 200 days of CMV-AV prophylaxis, especially among high-risk KTRs, which may lead to suboptimal efficacy for CMV prevention.

Abstract# LB 68

Cytomegalovirus Infection Among Adult Kidney Transplant Recipients: Findings From the USRDS-medicare Linked Database Study

A. Raval[1], M. Ganz[2], S. Alam[2], Y. Tang[1], C. Santos[3], *[1]Merck & Co., Inc., Rahway, NJ, [2]Evidera-PPD, Waltham, MA, [3]Rush University Medical Center, Chicago, IL*

Purpose: Cytomegalovirus infection (CMVi) is a frequent complication and significant cause of morbidity and mortality after kidney transplantation (KT). However, there are limited recent national data on the incidence of CMVi among KT recipients (KTRs). We examined the incidence of CMV infection overall and stratified by donor (D) and recipients (R) CMV serostatus pairing among adults undergoing KT in the United States (US).

Methods: A retrospective cohort design was utilized to examine the incidence of CMV infection among adult KTRs from the US Renal Data System Registry-Medicare linked data. Adults who received their first KT from July 1, 2011, through December 31, 2016, with continuous medical coverage for 6-month pre and 12-month post-KT were included. CMVi was considered as ≥ 1 medical claim with the International Classification of Disease, 9th Revision (ICD-9) codes of 078.5 or ICD-10 codes of B25.0, B25.1, B25.2, B25.8, B25.9, B27.1, H32.00, K87.00, K93.820 within 12-month post-KT. CMV antiviral (AV) prophylaxis was identified as ≥ 1 fill for (val)ganciclovir or (val) acyclovir within 28 days post-KT. Descriptive statistics were reported on the frequency and incidence of rates of CMVi for the study cohort and by D/R pairing/groups.

Results: The study cohort included 23,445 KTRs of whom 15%, 74%, and 11% had D+/R-, R+ and D-/R- CMV serostatus pairing groups, respectively. Overall, 77% received CMV AV prophylaxis, and 10% had CMVi within 12-month post-KT. KTRs with D+/R- CMV serostatus pairing had higher rates of CMVi (20%) compared to KTTs with R+ (9%) and D-/R- (2%) groups (see Table 1). The average time to first CMVi event was longer among KTRs with D+/R- in comparison to R+ or D-/R- group, and frequency of CMVi post-200 days was higher among D+/R- group.

Conclusions: Nearly one in ten KTRs had at least one medical claim for CMV infection. KTRs with D+/R- CMV serostatus pairing had a higher incidence rate of overall CMV infection and late infection post-200 days KT.

CMV Infection Among Individuals undergoing 1st KT (Overall and CMV serostaus)				
CMV Outcome	Overall	D+/R-	R+	D-/R-
Sample Size, n	23445	3,582	17,398	2,465
1st CMV infection, n(%)	2259 (9.6%)	716 (20.0%)	1,490 (8.6%)	53 (2.2%)
Time to 1st CMV infection post KT, in days, mean (SD)	125.6 (102.2)	165.9 (96.0)	107.4 (99.8)	94.2 (92.4)
1st CMV infection: 0-100 days post-KT 0-100 days, n(%)	1041 (46.0%)	211 (29.4%)	795 (53.3%)	35 (66.0%)
1st CMV infection: 100-200 days post-KT, n(%)	625 (27.7%)	219 (30.6%)	397 (26.6%)	9 (16.9%)
1st CMV infection: 200+ days post-KT, n(%)	593 (26.3%)	286 (39.9%)	298 (20.0%)	9 (16.9%)
Incidence Rate for CMV infection, in Person-Years IR (95% CI)	10.43 (10.01 - 10.87)	22.83 (21.19 - 24.56)	9.24 (8.78 - 9.72)	2.22 (1.66 - 2.90)

Abstract# LB 69

Impact of Cytomegalovirus Prophylaxis on Herpes Simplex and Varicella Zoster Virus Infections in Kidney Transplant Recipients

K. Ridgely[1], B. Crowther[2], P. Klem[2], K. Schoeppler[1], K. Schwarz[1], A. Nadrash[2], V. Lewis[1], E. Benamu[3], *[1]Department of Pharmacy Services, UCHealth University of Colorado Hospital, Aurora, CO, [2]Ambulatory Care Pharmacy Services, UCHealth University of Colorado Hospital, Aurora, CO, [3]Department of Medicine, UCHealth University of Colorado Hospital, Aurora, CO*

Purpose: To assess the impact of cytomegalovirus (CMV) targeted antiviral prophylaxis on the development of herpes simplex (HSV) and varicella zoster (VZV) infections after kidney transplantation.

Methods: This single center retrospective analysis at a large academic medical center included 987 patients who underwent kidney transplant between 1/1/2012 and 12/31/2018. Per institutional protocol, patients who were both CMV IgG recipient (R) and donor (D) seronegative or those who did not receive T-cell depleting induction therapy at the time of transplant received no antiviral prophylaxis thereafter. Those who were CMV R+ and received T-cell depleting induction or D+/R- received 3 or 6 months of valganciclovir (VGC) prophylaxis, respectively, with a target dose of 450 mg by mouth daily with appropriate renal adjustment. The primary outcome was a composite of HSV and VZV infection within the first 3 months after transplantation, defined as a prescription order for acyclovir or valacyclovir at appropriate treatment dosing regimens with confirmed therapeutic indication via chart review.

Results: HSV or VZV infection occurred in 6/688 (0.9%) of those who received VGC and 8/299 (2.7%) of those who did not receive prophylaxis at 3 months (p=0.055). There was a significant difference in HSV infection risk at 3 months between the groups (0.3% vs. 2.0%, p=0.011) (Table 1). No difference was seen in HSV or VZV infections at 6 months (Table 2).

Conclusions: Antiviral prophylaxis with VGC was associated with a decreased risk of HSV infections within the first 3 months after kidney transplantation with little effect on the development of VZV infections. These results indicate that VGC is effective at preventing both CMV and HSV infections in the early post-transplant period, therefore kidney transplant recipients not receiving antiviral prophylaxis with VGC, acyclovir or valacyclovir prophylaxis is warranted to mitigate risk of HSV emergence.

Table 1: Primary Outcome

	Valganciclovir N=688	No prophylaxis N=299	p-value
HSV or VZV at 3 months, n (%)	6 (0.9)	8 (2.7)	0.055
HSV at 3 months, n (%)	2 (0.3)	6 (2.0)	0.011
VZV at 3 months, n (%)	4 (0.6)	2 (0.7)	1

Table 2: Secondary Outcomes

	Valganciclovir N=688	No prophylaxis N=299	p-value
HSV or VZV at 6 months, n (%)	15 (2.2)	9 (3.0)	0.57
HSV at 6 months, n (%)	9 (1.3)	7 (2.3)	0.27
VZV at 6 months, n (%)	6 (0.9)	2 (0.7)	1
Time from transplant to infection, median days (IQR)	103 (87)	27 (37)	0.17
Time from transplant to HSV, median days (IQR)	110 (30)	48 (36)	0.3
Time from transplant to VZV, median days (IQR)	58.5 (76.8)	20.5 (6.5)	0.29
Hospitalized at time of infection, n (%)	4 (0.6)	1 (0.3)	1
Hospital LOS, median (IQR)	8 (8.8)	8 (0)	1
Site of infection			
Orolabial, n (%)	6 (40.0)	5 (55.6)	
Cutaneous, n (%)	7 (46.7)	3 (33.3)	
Orbital, n (%)	1 (6.7)	0	
Genital, n (%)	2 (13.3)	1 (11.1)	
Other, n (%)	2 (13.2)	1 (11.1)

Belatacept Pharmacokinetics in Patients with and without Infection

A. Bickenbach[1], M. McGowan[1], B. Miyagawa[2], T. Mizuno[2], A. Shields[3], A. Christianson[1], P. West-Thielke[4], J. Leone[5], E. Woodle[1], D. Kaufman[6], A. Wiseman[7], A. Vinks[2], R. Alloway[1], *[1]U Cincinnati, Cincinnati, OH, [2]Cincinnati Children's Med Center, Cincinnati, OH, [3]Christ Hospital, Cincinnati, OH, [4]UIC, Chicago, IL, [5]Tampa Gen, Tampa, FL, [6]U Wisconsin, Madison, WI, [7]Centura Transplant, Denver, CO*

Purpose: Two belatacept(BELA) fixed mg/kg dosing regimens, less intense(LI) and more intense(MI) were compared. The LI regimen was approved due to the higher risk profile of MI. Incidence of BK and herpes tended to be higher in pts with higher BELA troughs and a 17% increase in odds of serious infection was observed for every 10mcg/mL increase in the concentration average at 6 months(Cavg6mo). BEST samples were utilized to explore associations between BELA PK and infections.

Methods: Collected samples in BELA treated pts were utilized to analyze BELA troughs via validated quantitative enzyme-linked immunoassay. Clearance(Cl) was estimated using Bayesian estimation with a published population PK model as the Bayesian prior with the clinical software MWPharm++(Mediware). Allometric scaling accounted for body weight differences. Individual patient profiles were analyzed to estimate troughs, cumulative area under the curve(AUC) and Cavg. PK parameters were analyzed with clinical data of any infection, severe bacterial, fungal, or viral.

Results: 876 troughs in 191 pts showed agreement between observed concentrations and both population model-predicted and Bayesian estimated concentrations (R^2=0.84 and 0.88, respectively). BELA exposure was higher than reported previously. Inter-individual variability in Cl was low (CV=22%) and matched reports. No significant differences between allometrically standardized Cl estimates were observed. BELA AUC and Cavg were significantly higher in pts with any infection(n=132) including viral(n= 82) compared to those without(Figure 1). Logistic regression revealed increased probability of infection based on Cavg6 and 12mo exposure. No difference in exposure was observed in CMV(n=23) pts. Significant increases in AUC and Cavg were observed in BK(n=41). BK pts experienced 11.8-14.6% increase in AUC out to 12mo. The Cavg or AUC at infection event is shown in Figure 2. Mean time to BK was 190±163 days. No significant differences in exposure were observed in bacterial(n=163) or fungal infected(n=13) pts.

Conclusions: Higher BELA exposure was observed in pts with infection, particularly viral and BK . Effective CMV prophylaxis may prevent CMV in BELA treated pts regardless of exposure. BELA concentration controlled trials at lower doses may improve the overall infection, viral, and BK infection profile.

Figure 1. BEST Belatacept Model Predicted Trough Concentrations in Non-infection and Infection Patients. Dashed line Phase 3 target troughs for LI regimen

Abstract# 804

Significance of Detectable but Unquantifiable Viremias Post Renal Transplantation

M. Chaung, S. Puri, S. Bunin, Z. Mondal, O. Eletta, R. Pelletier, A. Bongu,
Robert Wood Johnson University Hospital, New Brunswick, NJ

Purpose: It is unknown whether the degree of the initial viremia following kidney (KT) or combined kidney-pancreas transplantation (SPKT) correlates with future allograft rejection or loss. We sought to characterize transplant outcomes based on initial BK virus and cytomegalovirus (CMV) level.
Methods: In this single center, retrospective, observational study 97 adult KT (88%)/ SPKT (12%) recipients (age≥18 years old) transplanted from 2018-2019 with first detectable CMV and BK viremia during their first year of transplant were included. Adults with BK or CMV viremia were divided into groups based on whether their initial PCR results were quantifiable (QL, Group1) or only detectable (DL, Group2). The primary end-points were biopsy proven acute rejection and graft loss following initial treatment for BK or CMV viremia. Initial treatment of BK viremia or CMV viremia was defined as any immunosuppression (IS) reduction (for BK viremia > 2000 copies/ml and CMV level >500 copies/ml).
Results: Demographics: Males (52%), Blacks (35%), deceased donor (68%) and thymoglobulin induction (97%). There were no differences in donor or recipient demographics between BK or CMV categories when comparing initial detectable (DL) and quantifiable (QL) groupings. Using detectability as the threshold, the incidences of BK and CMV in the first 6 months were 19% (18/97) and 41% (40/97) respectively. The median time to rejection overall was 214 (96, 373) days. 12/13 (92%) of those patients had a concurrent BK or CMV viremia. A viremia preceded a rejection in 5/6 cases with BK and 7/10 cases with CMV. Comparing DL and QL groupings, for BK/CMV there were no differences in primary end points, days to viremia, days to treatment, and percentage of patients requiring viremia targeted therapy (Table 1). 50% of BK and 40% of CMV patients with initial DL never progressed to QL.
Conclusions: Initial viremia for both BK and CMV does not seem to correlate disease severity or post-transplant outcomes.

Table 1: Outcomes for BK and CMV viremia based on initial levels

BK GROUP	Group1 (*start quantifiable*) n=9	Group2 (*start detectable*) N=14	p
Days to BK	88 (63, 231)	84 (34, 87)	.214
IS Reduction	89% (8/9)	72% (10/14)	.611
Days to IS Reduction	161 (105, 222)	168 (63, 203)	1
Any Rejection 1st year	33% (3/9)	21% (3/14)	.436
Days to 1st Rejection	315 (123, 467)	267 (105, 440)	.874
CMV GROUP	**Group1 (*start quantifiable*) n=22**	**Group2 (*start detectable*) N=27**	**p**
Days to CMV	138 (89, 162)	78 (28, 144)	.015
Days to IS reduction	158 (117, 229)	128 (70, 146)	.688
Any Rejection 1st year	18% (4/22)	19% (5/27)	.984
# Rejections	1 (0, 2)	1 (0,1)	.683
Days to 1st Rejection	318 (135, 404)	315 (123, 440)	.897

Abstract# 805

Influence of HLA Compatibility on Bk Virus Associated Nephropathy Among Japanese Living Donor Kidney Transplant Recipients

N. Fujiyama[1], M. Saito[2], R. Yamamoto[2], R. Sagehashi[2], T. Saito[2], S. Kashima[2], K. Numakura[2], S. Narita[2], T. Habuchi[2], S. Satoh[1], *[1]Center for Kidney Disease and Transplantaion, Akita University Hospital, Akita, Japan, [2]Department of Urology, Akita University Graduate School of Medicine, Akita, Japan*

Purpose: BK polyomavirus-associated nephropathy (BKVN) after kidney transplantation is associated with a high morbidity and higher risk of graft loss. In this study, the relationship between BKVN post-kidney transplantation and HLA, and between killer immunoglobulin-like receptor (KIR) compatibility of recipients and donors was evaluated.
Methods: We included 228 cases among patients who received a living kidney transplants at Akita University Hospital from December 2004 to November 2016. BKVN replication was evaluated by detection of decoy cells in urine cytology smears and/or immunohistochemical staining by simian virus 40 positive cells in graft biopsy. Using HLA and KIR haplotypes were determined by WAKFlow and LAB type reagents, HLA loci type and HLA match/HLA-KIR match between donor and recipient were evaluated.
Results: Eleven cases were diagnosed with BKVN infection after renal transplant (4.8% of the total). In the analysis using HLA loci type, BKVN was significantly high frequency in A24 and DR14 carriers compared with each non-carrier (8.4% vs 0.9%; p=0.011 and 12.8% vs 2.8%; p=0.011, respectively). In the analysis using HLA match, the incidence in the 2- or 1-match case group of HLA-DR14 was significantly higher than in the 0-match case group (19.0% vs. 3.4%, p=0.012) while there were no association of BKVN with other HLA match. In Kaplan-Meier analysis, HLA-A24 carrier, HLA-DR14 carrier and HLA-DR14 match were significantly high morbidity compared with non-carrier/match (p=0.009, p=0.005 and p=0.002, respectively). On the other hand, as a result of comparison among KIR haplotypes and of comparison with or without KIR-ligand match between recipient KIR and donor HLA, there were no significant different of BKVN frequency.
Conclusions: HLA and match/mismatch in kidney transplantation are important not only for suppressing alloresponse but also for predicting BKVN.

Abstract# 806

Dissecting the Intrarenal Immune Response to Viral Infected Cells in Pediatric BK Virus-associated Nephropathy (BKVAN)

D. M. Okamura[1], S. W. Jackson[1], V. R. Dharnidharka[2], J. M. Smith[1], *[1]Pediatric Nephrology, Seattle Children's Hospital & Research Institute, Seattle, WA, [2]Pediatric Nephrology, 2St. Louis Children's Hospital, Washington University School of Medicine, St. Louis, MO*

Purpose: BKVAN is not only a cause of acute renal allograft injury but is a recognized cause of chronic allograft disease and in some patients, allograft failure. Currently, there is little understanding of the intrarenal mechanisms involved in the resolution of BKVAN. To better understand these pathways, we investigated the intrarenal immune responses to BKV infected tubular cells.

Methods: We examined the course of three pediatric patients diagnosed with BKVAN: one progressive BKVAN leading to graft failure and two BKVAN with resolution of BK viremia, but with either new donor-specific antibodies (DSA) or new interstitial fibrosis/tubular atrophy (IFTA). Each patient had an initial biopsy prior to the diagnosis of BKVAN: two normal and one with Banff 1A rejection. Using digital spatial profiling with the human IO TAP panel v2 on the Nanostring GeoMX DSP, we identified regions of interest (ROI) with BK polyoma infected tubular cells in BKVAN biopsy samples and compared it with normal tubular ROI from baseline biopsy, n=8-12 ROI/biopsy. Signal intensities from equal area ROIs were normalized to host antibody levels (rabbit and mouse).

Results: Digital spatial profiling identified many upregulated proteins with significant differences between normal (n=24), rejection (n=12), and BKVAN biopsy groups (n=32) (P<0.0001). As expected, CD8 levels were approximately 13 times higher in BKVAN compared to normal (**Figure 1A**; P=0.012). There was a significant increase in CD20 levels (7.8-fold) that distinguished BKVAN from normal and rejection kidneys (**Figure 1B**, P<0.0001). Furthermore, activated macrophage markers such as CD44 and CD68 not only distinguished BKVAN from normal kidneys (**Figure 1C,D**, P<0.0001 and P=0.002, respectively) but also was associated with progressive BKVAN (P<0.01).

Conclusions: Although this study is limited by the low number of patients, it more accurately represents the intrarenal immune microenvironment of BK infected tubular cells compared to whole tissue investigations and needs further study. These results represent the first step to devise improved treatment strategies.

Abstract# 807

BKV-Associated Urothelial Carcinoma in Patients After Renal and Extrarenal Carcinoma

A. Schwarz[1], J. Schmitz[2], J. Gottlieb[3], C. Bara[4], H. Haller[1], J. Braesen[2], *[1]Nephrology Department, Hannover Medical School, Hannover, Germany, [2]Institute of Pathology, Hannover Medical School, Hannover, Germany, [3]Department of Pneumology, Hannover Medical School, Hannover, Germany, [4]Department of Thoracic Surgery, Hannover Medical School, Hannover, Germany*

Purpose: Polyomavirus BK (BKV) reactivation or transmission is a wellknown problem in renal transplant (TX) patients with BKV nephropathy and interstitial cystitis. The role of BKV-associated urothelial carcinoma is still debated.

Methods: We reviewed the clinical data of five patients with BKV-associated urothelial carcinoma to understand the difference of this severe late complication of renal and extrarenal TX compared to usual BKV-related problems in renal TX patients.

Results: Between 2014 and 2020, we saw five patients (three men and two women aged 49±17 yrs at TX) with urothelial carcinoma after renal (n=2) and extrarenal TX (heart 1, lung 1, and combined heart-lung 1). Basal immunosuppression consisted in tacrolimus, mycophenolate mofetil (MMF), and prednisolone (Predni) in 3 patients, and everolimus, MMF, and Predni as well as cyclosporine and Predni in 2 other patients. All patients had high viremia (n=5; maximum 596286±444272 copies/mL) and high viruria (n=4; maximum 7.5±5 billion copies/mL; one patient not tested) 4 to 7 years before diagnosis of urothelial carcinoma. Four of 5 patients had had BKV nephropathy 3 to 58 months after TX. Urothelial carcinoma was diagnosed 102±27.2 (71-144) months after TX. Three tumors were located mainly in the bladder, one in the TX ureter, one in both. All had carcinoma metastasis in the lymph system, 3 had also other meststases. Tumor histology was undifferentiated and grade 3 in all cases and showed distinct nuclear SV40 staining of the tumor cells. Cystectomy was performed in 3 cases, TX-ureterectomy in one renal TX and both in the other renal TX patient. Three patients died by metastatic tumor 3, 7, and 26 months after diagnosis. Two patients are alive 36 and 6 months after tumor diagnosis.

Conclusions: BKV-associated urothelial carcinoma is a late phenomenon after renal and extrarenal TX. Diagnosis occurs often delayed and at an advanced stage, since BKV problems mostly happen up to two years after renal and only rarely after extrarenal TX; therefore BKV testing usually is not done routinely late after renal and in general rarely done at all after extrarenal TX. Prognosis therefore is poor. Diagnosis may be suspected in cases of persisting high viruria, especially after preceding BKV nephropathy earlier.

Abstract# 808

Polyomavirus BK-Associated Nephropathy in Patients After Renal and Extrarenal Transplantation

A. Schwarz[1], J. Schmitz[2], J. Braesen[2], C. Bara[3], M. Sauer[4], H. Haller[1], J. Gottlieb[5], *[1]Nephrology Department, Hannover Medical School, Hannover, Germany, [2]Institute of Pathology, Hannover Medical School, Hannover, Germany, [3]Department of Thoracic Surgery, Hannover Medical School, Hannover, Germany, [4]Department of Pediatric Hematology, Hannover Medical School, Hannover, Germany, [5]Deparment of Pneumology, Hannover Medical School, Hannover, Germany*

Purpose: Patients with non-renal organ transplantation (TX) may suffer BK-viral nephropathy (BKVN) of their own orthotopic kidneys. We aimed to know if these patients with BKVN after non-renal organ transplantation differ from renal transplant (TX) patients with BKVN.

Methods: We followed retrospectively the clinical course of non-renal transplant patients with BKVN.

Results: Since 2001, we have seen twelve patients with biopsy-proven and one with clinically highly suggestive BKVN after non-renal organ transplantation (eight patients after lung, and two after heart TX, respectively; two after hematopoetic stem cell transplantation (HSCT); and one other patient without being transplanted at all but with biopsy-proven BKVN and interstitial renal infiltration of chronic lymphatic leucemia cells). All ten patients with lung and heart TX had calcineurin-based triple or dual immnosuppression. Four patients with chronic lung TX and both patients with HSCT and graft versus host reaction needed additional immunosuppression. Twelve of thirteen patients were men (92%); age at TX (n=12) was 39±18 yrs (5-69). Six of thirteen patients had end stage renal disease (ESRD, 46%), and the other seven had progressive renal insufficiency with eGFR <25mL/min (54%); five patients died (38%). Diagnosis by renal biopsy was established 87±107 months after TX in 12/13 patients. Maximum of viruria was 76,5±41,1 million copies/mL in 10/13 patients (3 not tested); and maximum of viremia 4,1±6,9 million copies/mL in 12/13 patients (1 not tested since no TX). First positivity of viruria and viremia PCR was measured 75±77 and 39±43 months in 9 and 12 patients, respectively, after TX.

Conclusions: In patients after non-renal Tx, BKVN of the orthotopic kidneys develops always by reactivation of their own viral population living in latency of urothelial cells. BKVN after non-renal TX occurs preferentially after lung, but also after heart TX and HSCT. Diagnosis is established late and with high viral load of long persistence. The patients develop severe renal insufficiency and often ESRD, five patients died. The course of BKVN of orthotopic kidneys after non-renal transplantation seems to be more malignant than BKVN after renal transplantation.

Abstract# 809

Conversion from Tacrolimus to Envarsus in Rapid Metabolizers for Prevention of BK Infection

G. Towns, G. Agarwal, C. Kew, *Transplant Nephrology, UAB, Birmingham, AL*

Purpose: The incidence of BK virus infection is high among rapid metabolizers (RM) in kidney transplant (KT) patients. RM can be identified using validated and clinically available information with tacrolimus concentration to dose ratio (c/d) < 1. The RM patients have high peak levels and greater tacrolimus exposure to achieve a therapeutic trough. As compared to immediate-release tacrolimus (IR-Tac), Envarsus, though its high bioavailability, has lower peak levels and overall tacrolimus exposure. This study investigated whether conversion of IR-Tac to Envarsus would reduce the incidence of BK infection among RM.

Methods: RM kidney transplant patients were identified using c/d <1, starting in March 2019, and prospectively followed for 12 months. All patients received standard of care immunosuppression with thymoglobulin induction, tacrolimus (trough level 8-12 ng/mL), mycophenolate mofetil (2000 mg daily), and prednisone at month 1. Patients met the criteria for the study if tacrolimus c/d remained < 1 at month 2 and serum BK PCR was negative at month 1. The study group was converted from IR-Tac to equivalent Envarsus at month 2. We retrospectively obtained the control group from January 2018 to February 2019 by chronologically screening every patient who underwent a KT prior to the study start date. We included everyone who met the above criteria of the standard immunosuppression and negative serum BK PCR at month 1. Control group data was collected 12 months post-transplant. Data are presented as counts and percentages or means. Significant differences between cases and controls were identified using t test and chi-square testing as indicated.

Results: We compared 35 prospective study patients with 46 historical controls. The cohort consisted of deceased donor KT (88.89%), with a mean age of 50.93 ± 10.65 years and predominantly black race (87.65%). There was no difference in baseline characteristics (Table 1). At 6 months post-transplant, there was no difference in the incidence of BK viruria or BK viremia (28 study group vs. 46 controls). As expected in an RM cohort, there was a high incidence of BK viruria (49.38%) and BK viremia (37.04%). It appears to date, at a mean follow-up of 10.43 months, there is no difference in the incidence of BK viruria, BK viremia, or BK nephropathy (Table 2) in the two groups.

Conclusions: We hypothesized that among rapid metabolizers, a lower peak level, and overall drug exposure with Envarsus would lead to a lower incidence of BK infection. There were no significant differences observed among the groups

Non-Organ Specific: Viral Hepatitis

Abstract# 810

Successful Single-Center Experience Using HCV+ Organs for Single and Dual-Organ Transplantation

S. Aslam, C. Logan, N. Law, J. Kerr, J. Kozuch, V. Ajmera, K. Afshar, A. Khan, E. Adler, K. Mekeel, E. Golts, V. Pretorius, *UCSD, San Diego, CA*

Purpose: National data demonstrate that increasing organ transplantation opportunities exist from hepatitis C virus (HCV)-infected individuals to HCV negative recipients.

Methods: We developed a clinical practice protocol in 2017 for the acceptance of HCV+ donors for HCV-negative patients who underwent solid organ transplantation. HCV+ donors included both viremic, i.e. HCV nucleic acid test positive (NAT+) as well as non-viremic, i.e. HCV antibody positive but NAT negative (Ab+/NAT-). Recipients were treated with direct acting antivirals (DAA) after documentation of infection transmission. After obtaining institutional review board approval, we retrospectively reviewed the outcomes at our institution.

Results: We transplanted 112 patients from HCV+ donors during the time-period 4/1/2017-10/31/2020 (Table 1). 97 patients received a single organ transplant and 15 received dual organ transplant. Median age of recipients was 59 years (IQR 49.5-65.5), 83/112 (75.5%) were male and median waitlist time was 214 days (IQR 45-902). All 88 patients receiving HCV NAT+ organs developed HCV viremia and 87 were treated in the post-operative period with 12 weeks of DAA. One recipient died soon after transplant from non-HCV related reasons and was not initiated on DAA. Additionally, 2/24 (16.7%) patients receiving HCV Ab+/NAT- organs developed HCV viremia (liver 1, heart-kidney 1) and were also treated with 12 weeks of DAA. DAA used included glecaprevir/pibrentasvir (68), sofosbuvir/velpatasvir (15), elbasvir/grazoprevir (2) and ledipasvir/sofosbuvir (4) with drug choice determined by patient's medical insurance coverage. Among patients treated with DAA, sustained virological response at 12 weeks after end of DAA therapy (SVR12), indicative of a treatment cure, was achieved in 72/74 (97.3%) recipients. 15 DAA- treated recipients are pending follow-up to assess for SVR12, two recipients failed the initial DAA course, one died prior to DAA initiation of unrelated cause and one died after completion of DAA but prior to completion of 12 weeks of follow-up to determine SVR12.

Conclusions: We report successful single-center experience using HCV+ organs for both single and dual solid organ transplant. As experience using such organs for transplant continues to increase and long term follow-up is obtained, HCV+ donors may be routinely used to increase the organ donor pool.

Table 1. Characteristics of solid-organ transplantation from HCV+ donors.

Transplanted organ(s)	HCV NAT+ n (%)	HCV Ab+/NAT- n (%)	Median waitlist time, days (IQR)	HCV outcome with additional details
Heart, n=30	24 (80%)	6 (20%)	146 (16-326)	-SVR 12: 23/24 (96.8%) -One failure -> Genotype 3, pre-treatment HCV viral load 1.4 million copies/mL. Initial DAA was 12 weeks sofosbuvir/velpatasvir -> retreated with 12 weeks sofosbuvir/velpatasvir/voxilaprevir but failed again -> currently clinically stable and on third course with glecaprevir/pibrentasvir + sofosbuvir + ribavirin
Lung, n=13	13 (100%)	0	35 (11-442)	-SVR12: 12/12 (100%) -One pending follow-up
Liver, n=30	13 (65%)	7 (35%) (1 became viremic)	184 (58-281)	-SVR12: 11/11 (100%) -3 pending follow-up
Kidney, n=84	25 (73.5%)	9 (26.5%)	1607 (941-2190.5)	-SVR12: 7/7T (100%) -8 pending follow-up
Heart-kidney, n=7	6 (85.7%)	1 (14.3% became viremic)	31 (10-76)	-SVR12: 5/6 (83.3%) -One failure -> Genotype 1a, pre-treatment HCV viral load 33.7 million copies/mL. Initial DAA was 12 weeks elbasvir/grazoprevir -> retreated with 12 weeks sofosbuvir/velpatasvir/voxilaprevir with SVR12. -One death unrelated to HCV prior to completion of follow-up
Heart-liver, n=2	2 (100%)	0	59.5 (45-74)	-SVR12: 2/2 (100%)
Heart-lung, n=1	1 (100%)	0	182 (NA)	-One pending follow-up
Liver-kidney, n=5	4 (80%)	1 (20%)	101.5 (66.5-691)	-SVR12: 2/2 (100%). -One pending follow-up, one death unrelated to HCV prior to DAA initiation.
Total, N =112	88 (78.6%)	24 (21.4%)	214 (IQR 45-902)	-SVR12: 72/ 74 (97.3%) 16 pending follow-up -Two failures -Two deaths unrelated to HCV

Abstract# 811

Hepatitis E Diagnosis and Management After Liver, Kidney, or Heart Transplant: A Single Center Experience

M. Carter[1], M. Fitzmaurice[2], S. Yeddula[2], A. Singh[2], S. Nagai[2], S. Jafri[2], *[1]Wayne State University School of Medicine, Detroit, MI, [2]Henry Ford Health System, Detroit, MI*

Purpose: Transplant-related Hepatitis E virus (HEV) infection is a rarely recognized entity with significant clinical importance given potential for chronic hepatitis post-transplant. We evaluated HEV diagnosis, treatment, and outcomes after liver, kidney and heart transplant in a single center.

Methods: We evaluated all patients transplanted at a single center and identified patients diagnosed with HEV by serologic testing. We gathered data on patient outcomes, laboratory evaluation, treatment course, reduction in immunosuppression, and mortality.

Results: 13 transplant recipients developed HEV infection between 2017-2020. The average age for all patients was 62 years (range 47-74 years) with 46% male. The average time between transplantation and positive HEV IgM antibody testing was 35 months (range 3-240 months). Ten patients received a liver transplant for reasons including Hepatitis C virus, Hepatitis B virus, alcoholic cirrhosis, and Hepatocellular Carcinoma. Two patients received a kidney transplant for SLE and hypertensive nephrosclerosis respectively. One patient had a heart transplant for hypertrophic cardiomyopathy.All 13 patients presented with elevated liver enzymes and were positive for HEV IgM antibody. Nine patients had an undetectable HEV PCR Quantitative. Four patients did not have HEV PCR testing done. Three patients were treated with ribavirin for an average of 84 days (range 56-120 days) with two patients at 800mg per day and one patient at 600 mg per day. One of these patients had a recurrence of HEV but recovered after immunosuppression was reduced. All three patients' liver enzymes normalized with therapy. Eight patients had their immunosuppression reduced without anti-viral treatment. Seven of these patients' liver enzymes normalized and they recovered. One of these patients died of acute pancreatitis two months after positive HEV IgM antibody. Two patients had spontaneous reduction of liver enzymes without treatment or change to immunosuppression.

Conclusions: The gravity of active HEV infections in transplant recipients necessitates prompt diagnosis and treatment. In order to prevent ongoing hepatic inflammation and irreversible damage, HEV PCR should follow a positive HEV IgM antibody test. The PCR confirmation is vital given that HEV IgM antibody testing may have false positivity for active infection. Ribavirin and reducing immunosuppression are effective treatments. Larger multi-center studies are needed to confirm the risks and benefits of adding ribavirin therapy versus simple reduction of immunosuppression as first line therapy of HEV post-transplant.

Abstract# 812

Processes to Successfully Utilize Hepatitis C (HCV) Infected Donor Kidneys as Standard of Care

A. Dao[1], A. Reyad[1], J. Guiteau[1], M. Madhrira[2], S. Allam[2], *[1]Transplant, Medical City Fort Worth, Fort Worth, TX, [2]Tarrant Nephrology Associates, Premier Physicians Group Health, Fort Worth, TX*

Purpose: Despite robust evidence supporting the safety and efficacy of HCV-infected donor kidneys, great heterogeneity continues to exist regarding centers willingness to utilize these in HCV negative recipients. In 2019, our transplant center began utilizing these kidneys as standard of care. Processes were approved by institutional and transplant quality teams. All patients received education regarding HCV-infected donors and were approached for consent during evaluation. Eligible candidates were discussed in multidisciplinary selection committee. Financial and case management verification of HCV treatment coverage is required prior to listing. Post-transplant, nephrology/pharmacy-driven monitoring/treatment were completed per center protocols. We report here the experience of our multidisciplinary comprehensive approach to utilizing HCV-infected donor kidneys.

Methods: Recipients of HCV-nucleic acid test (NAT) and/or antibody (ab) positive donors were prospectively monitored for protocol adherence. Retrospective chart review was completed for transplants between July 2019 and October 2020. Donor/recipient characteristics, clinical outcomes, and HCV treatment details were collected.

Results: During the time period, 152 kidneys were transplanted at our center, 30 (20%) were from HCV-infected donors. Donor/recipient characteristics are summarized in Table 1. Adherence to testing schedule per protocol was 100%. No HCV transmission occurred in recipients of HCVAb+/NAT- donor kidneys. HCV viremia was detected in all 20 recipients of HCVNAT+ donors. Treatments were initiated in all infected recipients within 1 month following transplant. All insurances required HCV genotype and prior authorization for medication approval. No therapy failure or resistance were reported. At last follow-up, 19 of the 20 patients completed HCV treatment, 16 patients achieved SVR-12, and 1 patient is yet to start therapy. Overall, 10 (33%) patients had transient transaminitis which resolved at last follow-up.

Conclusions: Safe and effective utilization of HCV-infected donor kidneys outside the context of clinical trials is feasible and requires center-specific protocols involving multiple disciplines. Partnership with a designated specialty pharmacy and protocolized pathways lead to prompt treatment initiation to reduce potential risk of HCV-related complications. HCV-infected donors continue to provide a significant source of kidneys to increase transplant volume and shorten wait time.

Abstract# 813

Not Always as it Seems: Lack of Hepatitis C Virus Transmission from Nucleic Acid Testing Positive Deceased Donors

A. Nishio Lucar[1], A. Kumar[1], S. Rao[1], V. L. Kelly[1], K. Coles[2], J. Kamal[1], C. W. Green[1], A. M. Doyle[1], *[1]Medicine, University of Virginia, Charlottesville, VA, [2]University of Virginia, Charlottesville, VA*

Purpose: Hepatitis C virus (HCV) + organs are increasingly use to transplant HCV naive candidates with good short-term outcomes. HCV transmission with HCV nucleic acid test (NAT) + donor is near to 100%. HCV-seronegative NAT+ donors indicate acute infection and carry high risk for infection transmission. Here we report a case series of solid organ transplant recipients (SOTR) of HCV NAT+ organs who did not develop viremia in their post-transplant period.

Methods: Retrospective review of adult HCV naive SOTR receiving HCV NAT+ organs since 10/2018. SOTR data obtained from electronic medical record and donor data from DonorNet.

Results: Out of 118 SOTR receiving HCV-positive organs, we identified 10 HCV naive SOTR receiving organs from 9 different HCV NAT+ donors without evidence of HCV transmission. Donors had a mean age of 35±16 y, 22% females, 22% Black, 22% history of IV drug use, 44% died from CVA/stroke. All donors were HCV NAT+, 44% were HCV seropositive. Median time of NAT collection to transplant was 34.4 hours. Recipients mean age was 56±9 y, 50% females, 50% Black and 60% received a kidney or kidney-pancreas transplant. All recipients were HCV seronegative. Anti-thymocyte globulin induction was given to 60% of recipients and 90% were maintained on triple immunosuppression. Median recipient follow up was 349 days (IQR 246-423). By 1 month post-transplant, all recipients had negative HCV viral load (VL). At 3 months, most recipients (80%) remained without detectable viremia including 1 liver recipient. From 2 SOTR without 3 month data, 1 had the 3 month VL pending at the time of this abstract and 1 had died from non-HCV related complications. HCV viremia details in Table 1.

Conclusions: Despite the high risk of HCV transmission when transplanting HCV NAT+ organs into naive recipients, we identified 10 SOTR where transmission did not occur at last follow up. This finding may be due to a low HCV viral replication at time of procurement and further virion removal through post-recovery organ washout. It is also possible HCV NAT testing was falsely positive, despite its high sensitivity and specificity (>98 and 99%, respectively). In conclusion, the infectivity of all HCV NAT+ donors may not be the same and thus, HCV NAT+ organs should continue to be used with confidence to expand access to a scarce resource.

Table | HCV NAT-positive recipients viremia progression over time

Recipient	Organ Type	Time since transplant (days)	HCV VL 2 weeks	HCV VL 1 month	HCV VL 3 months	HCV VL - Last negative (months)

Abstract# 814

Transplantation of Hepatitis C Positive Kidney and Pancreas Allografts Into Hepatitis C Naïve Recipients - A Single Center Experience as a Standard of Care

K. Yadav[1], A. Padiyar[2], K. Zhao[3], J. Rabets[3], A. Jittirat[2], S. Sclair[4], *[1]Transplant Surgery, University of Toledo Medical Center, Toledo, OH, [2]Nephrology, University Hospitals Cleveland, Cleveland, OH, [3]Transplant Surgery, University Hospitals Cleveland, Cleveland, OH, [4]Gastroenterology and Hepatology, University Hospitals Cleveland, Cleveland, OH*

Purpose: Transplantation of Hepatitis C positive organs into Hepatitis C naïve recipients is rapidly gaining widespread acceptance. We report our experience with transplanting HCV D+/R- kidneys at our institution as a standard of care.

Methods: Prospective kidney/SPK transplant recipients were approached at time of listing for Hepatitis C positive (Ab+/NAT - or Ab+/NAT +) kidney offers. Post-operative outcomes were assessed including Hepatitis C related outcomes and graft/patient outcomes.

Results: 50 patients received kidney transplants, 2 received SPK transplants. Out of the 52 patients, 10 organs were Ab+/NAT- while 42 were Ab+/NAT+. There was no seroconversion in the Ab+/NAT- cohort, and 100% seroconversion at 1 week in NAT+ cohort.Genotypes- 1A/1B/2/3 - 22/3/2/15 respectively. 6 patients received Ledipasvir/Sofobuvir, 16 patients Glecaprevir/Pibrentasvir, and 20 received Velpatasvir/Sofobuvir based on our institutional protocol.Therapy was initiated after a mean of 34 days post-transplant. Patient insurance was billed for DAA therapy with 100% approval. At end of treatment, 2/35 patients who have completed therapy continued to be PCR positive. Out of them, one patient had very low viral load which was undetectable on subsequent checks and achieved SVR. The other patient had negative PCR at 4 weeks of treatment but had subsequent treatment failure. He has started Velpatasvir/Voxilaprevir therapy with good initial response. 19 patients have achieved SVR thus far.Average donor KDPI was 62%, 8 (15%) donors had KDPI>85%. Average PRA for recipients was 16%. 13 (25%) patients had DGF. 7 (13%) patients developed acute rejection. 11 (21%) patients developed BK viremia, 7 developed BK nephropathy. 10 patients (19%) had a creatinine >2 at 4 weeks post-tx. There was no fibrosing cholestatic hepatitis C/ post-tx mortality.

Conclusions: Hepatitis C positive to naïve transplants can be done as a standard of care with good post-transplant outcomes. Early initiation of therapy is important. We found a higher incidence of BK viremia in these patients compared to standard. This has been reported by other groups and needs further research for better understanding.

Abstract# LB 70

Exploring the Correlation with Donor Hepatitis C Viral Load and Viral Kinetics in Naïve Kidney Transplantation Recipients

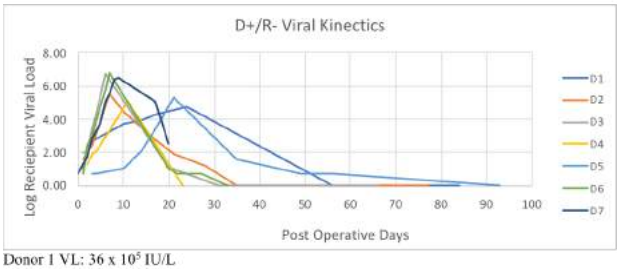
A. Brooks[1], A. Rechnitzer[1], R. Teo[1], D. Y. Goldstein[2], M. Narlieva[2], J. P. Rocca[1], M. Ajaimy[1], L. Liriano-Ward[1], Y. Azzi[1], C. Pynadath[1], P. Loarte-Campos[1], E. Akalin[1], M. E. Le[1], H. Yaffe[1], S. Greenstein[1], J. Torabi[1], M. M. Kinkhabwala[1], J. A. Graham[1], *[1]Montefiore-Einstein Center for Transplantation, Montefiore Medical Center, Bronx, NY, [2]Pathology, Montefiore Medical Center, Bronx, NY*

Purpose: The transplantation of Hepatitis C viremic (HCV) kidneys into uninfected recipients was made possible by effective direct acting anti-viral (DAA) therapy. This study aims to analyze the relationship between the donor HCV viral load and recipient HCV viral kinetics.

Methods: A single center retrospective study of HCV naïve patients that received HCV nucleic acid test positive kidneys (D+/R-) was performed. Seven *donors* had documented donor HCV viral loads at time of transplantation. Recipient viral loads were measured at regular intervals following transplantation. Area under the curve (AUC) was calculated to represent the extent of viral burden in the recipients. Recipient peak viral load, viral load AUC, recipient age, date of DAA initiation, and type of induction were analyzed using a linear regression model. D+/R- patients were monitored post-operatively for development of viremia and were all subsequently treated with DAAs.

Results: The average age in the D+/R- group was 43.4 years. The mean donor age was 36.5 years. KDPI was 57.1%. The mean *donor* viral load was found to be 3.05 x 10^6 UI/L. The mean peak recipient viral load was 2.23 x 10^6 IU/L. The mean AUC was 16.13 x 10^6 (IU/L x days). The linear regression model showed no correlation between the donor viral load and the recipient peak viral load or the recipient viral load AUC (p = 0.7 and 0.6). DAA initiation and induction was also non-predictive.

Conclusions: D+/R- transplantation offers patients an alternative strategy to increase access to kidney transplantation. Although, donor viral load did not correlate with the degree of recipient viremia, future studies may find this association significant with a larger cohort.



Donor 1 VL: 36 x 10^5 IU/L
Donor 2 VL: 44 x 10^5 IU/L
Donor 3 VL: 9.8 x 10^5 IU/L
Donor 4 VL: 1.8 x 10^5 IU/L
Donor 5 VL: 667 IU/L
Donor 6 VL: 2.1 x 10^5 IU/L
Donor 7 VL: 119 x 10^5 IU/L

Abstract# 815

Post-Transplant Lymphoproliferative Disorder as a Trigger for Hemophagocytic Lymphohistiocytosis in Solid Organ Transplant - Case Series

M. Doraiswamy, P. Singh, T. Pesavento, *Comprehensive Transplant Center, The Ohio State University Wexner Medical Center, Columbus, OH*

Purpose: Hemophagocytic Lymphohistiocytosis (HLH) is a hyperinflammatory syndrome characterized by cytokine storm from the activated reticuloendothelial system. Due to the nonspecific presentation and overlap with other illnesses, diag-

nosis is often delayed. It has a very poor prognosis, with a 40-50% mortality rate. Reports in solid organ transplant (SOT) are meager. In this study, we aim to evaluate the incidence, triggers, and outcomes of HLH in SOT.
Methods: We did a diagnosis-based database search of all the SOT performed at our center in the past ten years.
Results: Seven SOT recipients with a diagnosis of HLH [Five Kidneys, one Liver, and one Heart] were identified. Induction agents were ATG in all Kidney recipients and IL-2 receptor antagonist for Liver and Heart transplant. Maintenance agents were Calcineurin Inhibitors and Myfortic. The median time to diagnosis post-transplant was 2 years [1-13]. All recipients were Caucasians, 72% male, and the median age of diagnosis was 50 years [28-72]. The presentation included fever, acute hypoxic respiratory failure, shock, altered mental status, hemiplegia, tremors, and hearing loss. Labs showed hyperferritinemia (8000-124,000 ng/mL), elevated Interleukin 2 receptor [1600-6500, normal 139-579 pg/mL], hypertriglyceridemia [613-765-normal less than 150mg/dL], transaminitis, coagulopathy, and pancytopenia. Bone marrow (BM) biopsy demonstrated hemophagocytosis in 72% of patients. This is consistent with previous reports where 25% could have a negative biopsy. The triggers for HLH were EBV positive PTLD (4 cases, EBV PCR 0.3-10 million IU/mL), CMV (PCR - 70 million IU/mL), Ehrlichia, and Clostridium difficile. Treatment modalities used were immunomodulatory agents (dexamethasone, anakinra, ruxolitinib), PTLD guided treatments (R-EPOCH, rituximab, etoposide, prednisone, vincristine, cyclophosphamide, and doxorubicin), and treatment of inciting illness (doxycycline for the Ehrlichiosis and ganciclovir/foscarnet for CMV]. Both patients who died were Kidney transplant and died within a month of diagnosis. The first patient was a 72-years old male with CMV titers of 70 million. He initially responded to dexamethasone, anakinra, and ruxolitinib but later developed multi-organ failure. The second patient was 59-years old with EBV positive PTLD (PCR - 10 million) and was treated with R-EPOCH and anakinra. Overall, the mortality was 28%, which is less than previously reported studies and could be due to early treatment initiation.
Conclusions: Our case-series suggest that severe infections especially EBV positive PTLD, and elderly recipients have a poor prognosis. Early empiric dexamethasone improves outcomes and should be considered if HLH is suspected without waiting for the BM biopsy. The development of a registry for SOT with HLH would enhance our understanding of this syndrome.

Kidney Deceased Donor Allocation

Abstract# 823

Black Patients Do Not Have Worse Short-Term Outcomes After Receiving High KDPI (>85%) Kidneys

K. Atiemo[1], S. Guisti[1], K. Guo[2], T. Amankonah[1], A. Vijay[1], A. Paramesh[1], M. Killackey[1], H. Jeon[1], L. Zhao[2], D. Ladner[2], *[1]Tulane University, New Orleans, LA, [2]Northwestern University, Chicago, IL*

Purpose: Some studies have suggested Black kidney transplant recipients have an increased incidence of graft failure and worse survival. We examined whether this finding is consistent using a cohort of recipients of high KDPI (gt85%)/lower quality grafts.
Methods: National data (UNOS) and Multivariable Cox Models were used to assess death-censored graft failure and survival at 1-year post kidney transplant.
Results: 2,845 adults who received a deceased donor kidney only (multiorgan excluded) categorized as high KDPI >85% for the first time (6/1/2015 to 6/1/2018) met inclusion criteria. 984 (35%) were White, 997 (35%) were Black, 583 (20) were Hispanic and 281 (10%) were Asian. The median KDPI for Whites was 90% (IQR 87%-94%), Blacks 90% (IQR 87%-94%), Hispanics 90% (IQR 87%-93%) and Asians 89% (IQR 87-93). The median EPTS score for Whites was 74% (IQR 56%-89%), Blacks 75% (IQR 51%-91%), Hispanics 81% (61%-91%) and Asians 77% (58%-91%). Graft failure rate for Whites was 7%, Blacks 7%, Hispanics 4% and Asians 5%. Survival for Whites was 93%, Blacks 95%, Hispanics 94% and Asians 95%. After adjusting for age, gender, insurance, education level, cause of renal failure, waiting time, number of HLA mismatches and cold ischemic time there were no racial differences in death censored graft failure. Black vs White [HR 0.89 (95% CI 0.6-1.3)]; Hispanic vs White [HR 0.63 (95% CI 0.4-1.1)] and Asian vs White [HR 0.69(95%CI 0.4-1.2)]. Similarly, after adjusting for EPTS score, BMI, gender, insurance, education level and cold ischemic time no racial differences in 1-year survival were observed. Black vs White [HR 0.80 (95% CI 0.6-1.2)]; Hispanic vs White [HR 1.1 (95% CI 0.7-1.7)] and Asian vs White [HR 0.82 (95%CI 0.5-1.5)].
Conclusions: Concern for poorer outcomes among Black recipients of high KDPI kidneys may be unwarranted at least in the short-term. Greater utility can be made of high KDPI kidneys for which survival benefit has been demonstrated yet are still discarded at a high rate.

Abstract# 824

Low Immunogenic Donors Improved Survival of Kidney Transplants in African American Recipients

D. Bekbolsynov[1], R. Green[2], B. Mierzejewska[1], O. Ekwenna[1], M. Rees[1], S. Stepkowski[1], *[1]University of Toledo, Toledo, OH, [2]Bowling Green State University, Bowling Green, OH*

Purpose: Kidney transplants fail more often in African American (AA) than in Caucasian (CAU) recipients. We calculated the hydrophobic mismatch score (HMS) from polymorphic amino acids out of donor/recipient HLAs to select low immunogenic kidney transplants for African American patients.
Methods: The HMS immunogenicity (IM) on a scale of 0-20 for 64,053 AA and CAU recipients was correlated with Kaplan-Meier survival estimates and Cox regression analyses.
Results: The median kidney graft survival was 12.0 years in AA vs. 18.6 years in CAU recipients, a 6.6-year difference ($p<0.001$). Our analysis showed that AA recipients had higher both donor/recipient HLA-A/B/DR disparities and HMS IM values than CAU recipients (both $p>0.001$). We performed a re-matching simulation of 5,000 donor/recipient pairs with a priority for either 1,000 AA recipients or 4,000 CAU recipients. When 1,000 AA were matched first with 5,000 donors, 27.2% found HMS=0 donors, 44.5% HMS≤1.0 donors, and 66.5% HMS≤3.0 donors, all with an improved graft survival (Table 1). When CAU recipients were prioritized, AA patients found significantly less donors (Table 1). Importantly, preferential re-matching of AA recipients still allowed to accommodate the vast majority of CAU recipients: 35.8% with HMS=0 donors; 55.8% with HMS=2 donors and 74.6% with HMS=7 donors. Preferential CAU re-matching only slightly increased CAU re-matching, while dramatically decreased chances for AA recipients.
Conclusions: Because higher HMS threshold is acceptable for CAU patients, the preferential AA matching significantly increased chances in finding low IM donors for AA recipients, but still providing excellent chances to find low IM donors for CAU recipients.

Recipient race	HMS Value	% re-matched AA first (±SD)	% re-matched CAU first (±SD)	Median survival (95% CI)
African Americans	0	27.2 (±1.7)	3.7 (±0.3)	16.1 (12.3-NA)
	1.0	44.5 (±1.2)	7.5 (±0.7)	16.1 (13.9-NA)
	2.0	57.2 (±1.5)	12.4 (±0.7)	14.6 (12.3-16.1)
	3.0	66.5 (±1.1)	18.0 (±0.8)	13.9 (11.9-15.0)
	7.0	87.6 (±1.0)	39.4 (±1.2)	11.9 (11.5-12.6)
Caucasians	0	35.8 (±0.5)	43.9 (±0.7)	21.6 (NA-NA)
	1.0	44.5 (±0.5)	55.6 (±0.8)	24.1 (NA-NA)
	2.0	53.8 (±0.7)	65.6 (±0.6)	22.6 (NA-NA)
	3.0	60.5 (±0.5)	72.3 (±0.6)	22.5 (18.3-NA)
	7.0	74.6 (±0.6)	85.6 (±0.5)	18.7 (18.1-NA)

Abstract# 825

VO_{2peak} Differentiates Survival Post Kidney Transplant

H. Chakkera[1], B. Kaplan[2], P. Budhiraja[1], R. Butterfield[1], *[1]Mayo Clinic Hospital, Phoenix, AZ, [2]Baylor Scott and White Health, Temple, TX*

Purpose: The OPTN/UNOS utilizes the calculated *estimated posttransplant survival* (EPTS) score as the measure of post-kidney transplant survival to guide allocation of deceased donor kidney transplantation. This score does not include any metric of functional capacity. Peak oxygen uptake (VO_{2peak}), is an established predictor of survival among both the general and diseased populations.
Methods: We assessed the association and discriminative capacity of VO_{2peak} and that of EPTS score and all-cause mortality post-kidney transplant. Additionally, we assessed the *"mortality risk"* lower VO_{2peak} conferred on those patients with low EPTS score
Results: The study cohort included 293 patients with at least 3 year follow-up. 76.1% were deceased donor transplants. Mean follow-up period was 6.0 years. The mean transplant age was 57.6 years, 61.4% were male, 15.8% with history of coronary artery disease and 48.8% diabetic . The median VO_{2peak} was 15.0 ml/Kg/min. Through last follow-up, the cohort had 38 (13%) deaths. A 1 unit increase in the VO_{2peak} conferred approximately a 10% reduction in mortality [Unadjusted Hazard Ratio (95% Confidence Interval) = 0.90 (0.82-0.98), p = 0.018] and a 10 unit increase in the EPTS score calculated at transplant conferred approximately a 29% increase in mortality [HR (95% CI) = 1.29 (1.13, 1.47), p = 0.001]. In an adjusted

survival model (N= 293), Harrell C-Statistic (Standard Deviation) for the model with VO_{2peak} was 0.76 (0.04) indicating good discriminatory ability of VO2peak and all-cause mortality.

Lower pre-transplant VO_{2peak} and higher EPTS score conferred higher risk of post-transplant mortality. Among the cohort of "low-risk" patients (patients with EPTS score less than 50) those with lower VO_{2peak} had significantly higher risk of mortality (log rank p=0.045)., Figure 1. In fact, the mortality risk among those with *low-EPTS (*less than *50) and low* VO_{2peak} less than12ml/Kg/min was equivalent to those with high EPTS (greater than 80) score., Figure 2.

Conclusions: We concluded all EPTS is not the same. Functional capacity as defined by VO_{2peak} is an important reflection of post-transplant survival**.** VO_{2peak} is able to identify those with low EPTS who have similar survival to that of high EPTS phenotype.

Figure 1

Time-to-Event Survival Comparison of Low TX EPTS (<50): Low VO_{2peak} (<12) vs High VO_{2peak} (>15)

Abstract# 826

Outcomes of Deceased Donor Transplants with Donor Specific Antibodies Before and After the New Kidney Allocation System

R. Crew, P. Khairallah, S. S. Patel, *Columbia University, New York, NY*

Purpose: KAS forced centers to list unacceptable HLA antigens. Some centers excluded antigens at any level of anti-HLA Ab. Our center only excluded antibodies posing excess risk (ie mean fluorescence intensity [MFI] >3000). We hypothesized that the restriction in anti-HLA levels improved outcomes of +DSA DDRTx.

Methods: We reviewed our database to identify +DSA DDRTx recipients from 1/1/2010-12/3/2014 (last day prior to KAS) and from 12/4/2014-8/31/2020. We recorded data on induction, anti-HLA DSA measured by Luminex®, rejection rates, renal function, graft loss and death.

Results: 86 of 565 DDRT had DSA pre-KAS compared to 74 of 538 DDRT after KAS. Follow up was 6.35 (IQR 3.2-8) and 3.1 (IQR 1.2-3.9) years respectively ($p < 0.001$). Both groups had a similar % of women with similar ages but different induction strategies (Table 1). Our protocol +DSA pts changed during this time period, leading to more post-KAS patients getting IVIg/Rituximab induction to prevent AMR and more protocol biopsies (87% vs 23%, $p < 0.01$). The type of anti-HLA Abs (class 1, 2, or both) were not different between groups but the DSA MFIs were significantly lower post-KAS. Rejection was more common post-KAS (81% vs 65%), which was entirely explained by the increased use of protocol biopsies. Patients transplanted post-KAS were diagnosed with AMR significantly later. ACR occured earlier and was significantly milder with more frequent borderline rejections. Despite the high rejection rate, kidney function at 1 year was excellent with no difference between groups (median 1.57 [IQR 1.26-2] mg/dL vs 1.42 [IQR 1.27-1.81], p 0.17). Death censored graft survival was not significantly different at 1 year (94.5% vs 98.7%) or at 3 years (84.8% vs 96%).

Conclusions: Despite listing unacceptable HLA antigens postKAS, a similar percentage of our DDRTx had DSA, though at much lower MFI. The overall renal function is excellent and graft survival comparable to UNOS reported outcomes for DDRTx at 1 year (93.2%) and 3 years (85.1%).* These outcomes suggest that transplanting sensitized patients with low level MFI is worthwhile compared to continuing dialysis while awaiting an offer without DSA.

Abstract# 827

Titer Stability vs. Terminal Pre-transplant Titer: Titer History is Irrelevant for A_2 to B Transplantation

A. Gilbert[1], S. Radomski[2], J. Vucci[1], B. Thomas[1], M. Cooper[1], *[1]Medstar Georgetown Transplant Institute, Washington, DC, [2]Johns Hopkins Medical Center, Baltimore, MD*

Purpose: Minor ABO incompatibile (ABOi) transplants from blood group A_2 or A_2B donors have increased since 2014, but initial guidance suggested that establishing an anti-A titer history is critical for effective transplantation. We reviewed our center's data to determine the relevance of the anti-A titer history in transplant outcomes.

Methods: This is a retrospective study. We reviewed all patients who received kidneys across minor ABOi. All patients getting minor ABOi transplants received standard treatment without any additional plasmapheresis. Recipients were categorized as those with only a single titer measurement pre-transplant vs those who had a titer history with readings over at least 3 months. For those with a titer history, we further stratified patients into those with persistently low titers (less than 1:8) and those that had at least 1 high titer but whose titers returned to low levels prior to being transplanted. The outcome of rejection or graft loss was evaluated using Kaplan-Meier plots and analyzed with the Mantel-Cox log rank test.

Results: Among our minor ABOi recipients, we found 15 had only a single anti-A titer and 48 had at least a 3 month titer history. We also identified 46 recipients who were transplanted with persistently low titers compared with 13 who had been identified with one or more high titers that returned to low levels by the time of transplant. Kaplan-Meier analysis showed no advantage in having an extended titer history (figure 1). Mean creatinine at 3 months and 1 year were not statistically different between the groups (1.55 vs 1.54 at 3m p=0.96, 1.57 vs 1.51 at 1 yr p=0.75). Similarly, in those with a history, a prior high titer that resolved before transplantation was associated with no increased incidence of graft loss or rejection (figure 2). Mean creatinine at 3m and 1yr were statistically similar (1.86 vs 1.50 at 3m p=0.10, 1.57 vs 1.43 at 1yr, p=0.53)

Conclusions: Contrary to common practice, a recipient's anti-A titer history demonstrated no significance in predicting graft outcomes as long as the titers were low at the time of transplant. Transplantation across minor ABOi does not require a titer history to be safe and effective.

Abstract# 828

HLA Haplotype Frequency and Racial Disparities in Access to Transplant Among Highly Sensitized Kidney Transplant Candidates

L. Gragert[1], M. Kadatz[2], D. Chang[2], H. Gebel[3], D. Stewart[4], E. Kransdorf[5], S. Brar[2], S. Vaishnav[2], J. Gill[2], J. Lan[2], *[1]Tulane University, New Orleans, LA, [2]University of British Columbia, Vancouver, BC, Canada, [3]Emory University, Atlanta, GA, [4]UNOS, Richmond, VA, [5]Cedars-Sinai, Beverly Hills, CA, Canada*

Purpose: Despite implementation of the Kidney Allocation System (KAS) which prioritizes sensitized patients, sensitized Black individuals are less likely to receive a transplant than non-Black individuals on the waitlist. Given zero-mismatch transplants are more common among sensitized patients, we hypothesized that more sensitized Black candidates have rare HLA genotypes, resulting in fewer potential matches from the donor pool and a lower likelihood of transplantation compared with non-Black candidates.

Methods: We analyzed a retrospective cohort of adult kidney transplant candidates (N=87174) from the 2019 USRDS database who were waitlisted post-KAS (Dec 4, 2014). The most likely HLA genotype for each candidate was imputed using the NMDP HapLogic algorithm from serologic HLA typing and categorized into "Common", "Intermediate" and "Rare" based on observed frequencies in the overall candidate population. Cumulative incidence of transplant from listing date was stratified by cPRA, race, and HLA genotype frequency.

Results: Black candidates had reduced probability of transplantation compared to non-Black candidates only when cPRA was >= 80%, and this disparity widened with higher cPRA (Fig 1). This effect remained significant after adjusting for competing risks of death/waitlist removal and ABO blood group. Candidates with common HLA genotype frequencies had the lowest incidence of transplantation in all candidates; however, Black candidates had a lower cumulative incidence of transplant relative to non-Black candidates, regardless of HLA genotype frequency (Fig 2).

Conclusions: Disparity in access to transplant between Black and non-Black transplant candidates is greater with increasing cPRA above 80%. This disparity is not explained by HLA genotype frequencies. Why the disparity widens with increasing cPRA remains uncertain. Contrary to our hypothesis, patients with common HLA frequency had the lowest access to transplantation. This unexpected phenomenon requires further studies.

Abstract# 829

The Incremental Cost of Transplanting Patients with 100% cPRA Under the Kidney Allocation System: A Single Center Analysis

R. Gumber, E. Kraus, K. Jackson, N. Alachkar, *Nephrology, Johns Hopkins University School of Medicine, Baltimore, MD*

Purpose: Our group has described excellent three year patient and graft survival in patients with 100% cPRA undergoing kidney transplantation under the Kidney Allocation System (KAS) (Jackson et al. AJT;20(10):2890-2898). However, there may be incremental costs of kidney transplant compared to patients with 0% cPRA associated with immunosuppression, organ allocation, hospital length of stay and readmissions. We studied the incremental cost of transplanting patients with 100% cPRA compared to patients with 0% cPRA under KAS in a single center.

Methods: Cohort of patients with 100% cPRA (n=97) and 0% cPRA (n=180) who underwent kidney transplantation from December 2014 to 2019 were retrospectively reviewed. All patients received induction therapy with anti-thymocyte globulin and high dose steroids. Recipients with presence of DSA or repeat mismatches were also given Rituximab, and those with DSA at flow cytometric cross-match level (n=6) were treated with plasmapheresis and intravenous immunoglobulin. Maintenance immunosuppression was tacrolimus, mycophenolate mofetil, and prednisone.

Results: The average cost of hospitalization for kidney transplantation (sum of hospital charges and professional fee) was $189,975 for patients with 100% cPRA and $191,700 for 0% cPRA (p-value=0.9) with similar length of stay (median=8 days). We evaluated surrogates for costs incurred after index transplant admission. 57.7% of patients with 100% cPRA versus 43.9% with 0% cPRA needed readmission within 12 months post kidney transplantation (p-value=0.028). Amongst patients readmitted, there was no difference in number of readmissions (median=2), or in readmissions within 30 days of kidney transplantation (100% cPRA=44.6%, 0% cPRA=43%). Cumulative length of stay during readmissions was similar in both groups (median=8 days). Table below summarizes these results.

	100% cPRA: Average/ Median (IQR)	0% cPRA: Average/ Median (IQR)
Hospital charges: Index admission ($)	161,664/152,783 (132,644-178,544)	154,698/135,064 (117,947-163,687)
Professional fee: Index admission ($)	28,311/24,966 (23,285 -29,271)	37,002/26,604 (21,296-35,977)
Length of stay (LOS): Index admission (days)	11/8 (6-12)	11/8 (6-13)
Readmissions (n)	2.07/2 (1-2)	2.06/2 (1-2)
LOS: readmissions (days)	13.5/8 (4-14.7)	14.3/8 (4-19)

Conclusions: Compared to 0% cPRA, patients with 100% cPRA patients did not have an incremental cost of undergoing kidney transplantation but had an increase in readmissions during the first year post transplant.

Abstract# 830

Effect of HLA-DR Mismatches on Graft Outcomes of Kidney Transplant from Elderly Donors

P. Homkrailas, S. Bunnapradist, *David Geffen School of Medicine at UCLA, Los Angeles, CA*

Purpose: Human leukocyte antigen (HLA)-DR has been shown to be more immunogenic than HLA-A or -B. The impact of HLA-DR mismatches remains unclear among kidney transplant from elderly donors. Here we report the effect of HLA-DR mismatches on graft rejection and graft survival among these patients.

Methods: The OPTN/UNOS data of kidneys from donors aged ≥65 years, transplanted between 2000-2018 were included. Study populations were grouped into recipients aged ≥65 years (old-old) and recipients aged <65 years (old-young).

Results: A total of 8,826 KTXs were included, which 50.7% were old-old. There were 26.5% and 24.9% living donor transplant in old-old and old-young groups, respectively. The median follow-up time was 5 years (IQR 2.2-8.8). KTXs with 0, 1 and 2 HLA-DR mismatches were 9.3%, 40.8% and 49.9% of old-old group, and 13.2%, 43.2% and 43.6% of old-young group, respectively. There were lower rejection rates in old-old group with 0, 1 and 2 HLA-DR mismatches which were 8.7%, 11.3% and 13.0% compared to old-young group which were 12.2%, 14.9% and 14.8%, respectively. Univariate analysis and multivariate analysis including recipient age, HLA-A and -B mismatches, panel reactive antibody, previous transplant, cold ischemic time, and delayed graft function showed that HLA-DR mismatch was associated with an increased risk for rejection (HR 1.13; 95%CI 1.04-1.23 and aHR 1.12; 95%CI 1.02-1.17 per each degree of mismatch). In old-old group, there were no differences in 5-year death-censored graft survivals (DCGSs) which were 81.7%, 80.8% and 82.6% when HLA-DR mismatches = 0, 1 and 2, respectively (p=0.51). In old-young group, there were statistically significant lower 5-year DCGSs when HLA-DR mismatches = 0, 1 and 2 which were 80.6%, 76.6% and 75.0%, respectively (p=0.01).

Conclusions: HLA-DR mismatches in KTX from elderly donors had no significant effect on DCGSs if transplant into older recipients but associated with statistically significant lower DCGSs if transplant into younger recipients. HLA-DR mismatches were an independent risk factor for graft rejection in both elderly and younger recipients. Comparing within each degree of HLA-DR mismatch, older recipients had better DCGS and lower rejection rates than younger recipients.

Abstract# 831

Organ Decline Rate and Outcomes of Shared Kidneys from OneLegacy OPO Donation Service Area in Los Angeles

M. Hussain[1], P. Homkalrias[1], K. Wheeler[2], G. Danovitch[1], S. Bunnapradist[1], *[1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]OneLegacy, Los Angeles, CA*

Purpose: Background: 20% recovered kidneys are discarded in the US. Southern California has a high number of End-Stage Kidney Disease patients and the waitlist time is one of the longest in the country.

Objectives: In this study we aimed to evaluate outcomes of organs recovered from donors in OneLegacy OPO representing seven counties of the greater Los Angeles area and to identify reasons of local organ decline.

Methods: We obtained data from UNOS and the Organ Procurement Organization (OPO), OneLegacy for kidneys under their donation service area (DSA) between January 2015 and August 2020. We calculated the local organ decline rate defined as the percentage of recovered organs declined by all centers under the OPO's DSA and shared outside the DSA. We also evaluated the offer refusal rate defined as organ offers that were refused by centers within the OPO's DSA.

Results: Out of 8113 kidneys offered for transplant, 6408 (79%) were refused by centers within the OPO's DSA at least once before being accepted. 1258 out of 7894 (15.9%) kidneys that were recovered locally within the OPO's DSA were subsequently transplanted out of the DSA. Out of the 1258 kidneys that were shared, 28 grafts had the composite outcome of primary failure and primary non-function. 219 kidneys were not offered for transplant and were discarded at the time of recovery. The most common reasons for offer refusal were "donor age or quality" (36.8%) and "patient ill, unavailable, refused or temporary unsuitable" (35.3%).

Conclusions: The local organ decline rate is significant in our DSA. A significant number of kidneys that were declined in this DSA were transplanted and 2.2% had primary non-function. Opportunities for increased utilization of these organs within the service area are being explored.

Abstract# 832

Sharing Under KAS - What is the Impact According to KDPI?

M. Jacobs, R. Stratta, C. Jay, *Wake Forest Baptist Health, Winston Salem, NC*

Purpose: The new Kidney Allocation System (KAS) implemented in 2014 was designed to facilitate sharing of kidneys due to changes in prioritization of highly sensitized patients and other groups. We sought to determine effects on sharing across pre- and post-KAS eras according to the Kidney Donor Profile Index (KDPI).

Methods: Using UNOS data, we compared local, regional, and national utilization for deceased donor kidney transplants (DDKT) alone according to KDPI strata and KAS era: Era 1 (2010-2011, pre-KDPI), Era 2 (2012-2013, pre-KAS), Era 3 (2014-2015, early post-KAS), Era 4 (2016-2017), and Era 5 (2018-2020).

Results: Since KAS, sharing of kidneys increased across all KDPI groups, and is more pronounced with increasing KDPI. Most notably, regional utilization more than doubled for KDPI >85% kidneys while local use decreased by 30% from Era 1 to 5 (Table 1). However, a 60% increase in absolute numbers of DDKTs performed from Era 1 to Era 5 compensated for increased sharing such that local DDKT volumes rebounded by Era 5. Conversely, sharing for calculated panel reactive antibody (cPRA) 99-100% patients increased post-KAS across all KDPI groups but the effect was more pronounced with lower KDPI strata (89% increase in sharing from Era 1 to 5 for KDPI 0-20%, and a 32% increase for KDPI >85%). However, sharing of kidneys for high cPRA patients accounted for only 23% of shared kidneys and 8% of DDKT alone by Era 5. Consequently, in Era 5, 70+% of kidneys in the 3 lower KDPI strata were transplanted locally whereas 50% of kidneys in the highest KDPI strata were shared.

Conclusions: KAS increased sharing across all KDPI strata with the biggest change occurring in increased regional utilization of KDPI >85% organs. Increasing DDKT volume has offset any reductions in absolute number of local transplants despite increasing sharing. Increased sharing for cPRA 99-100% patients has occurred across KDPI, particularly in the lower KDPI strata, but this represents a minority of kidneys shared.

Abstract# 833

Impact of the Kidney Allocation System on Kidney Transplant Outcomes in Patients with Long Dialysis Treatment (> 10 Years)

M. Kadatz, S. Vaishnav, S. Brar, D. Chang, J. Lan, J. Gill, *Medicine, Division of Nephrology, University of British Columbia, Vancouver, BC, Canada*

Purpose: Prior to the new kidney allocation system (KAS), patients treated with dialysis for > 10 years before transplantation were shown to derive a survival benefit from transplantation (Gill CJASN 2017). With the new KAS, the accrual of waiting time was back-dated to the date of first chronic dialysis for patients wait-listed after the start of chronic dialysis treatment. This led to a large increase in wait-list activations of patients with long dialysis vintage >10 years who had never been previously wait-listed. The outcomes of these patients with long dialysis vintage >10 years who were opportunistically wait-listed after the new KAS are unknown.

Methods: The study included n = 1446 adult > 18 years patients in the 2019 USRDS data base who were wait-listed for a kidney transplantation after >10 years of dialysis treatment in a 12 month period after the implementation of the new KAS in Dec. 2014, and a control group of n=1183 patients with >10 years of dialysis treatment who were wait-listed for transplantation in the 12 months prior to implementation of the new KAS. Patient characteristics pre- and post- KAS were compared, and access to transplantation was compared with cumulative incidence curves. Outcomes including overall survival, all cause graft loss (ACGL), death censored graft loss (DCGL), and death with function (DWF) pre- and post- KAS were compared with univariable and multivariable models.

Results: Patients with long dialysis vintage prior to waitlisting were similar pre- and post- KAS, being predominantly black (58%), Medicare insured (76%) and not highly sensitized. Those listed post-KAS had improved access to transplantation compared to those listed pre-KAS (78% vs 31% transplanted at 3 years after listing) (Fig 1A). Among patients who received a transplant (n = 686) pre and post KAS (n = 974) there was no difference allograft survival (Fig 1B). The overall unadjusted survival of waitlisted individuals was superior post-KAS compared to post KAS (Fig 1C).

Conclusions: The new KAS has successfully improved access to transplantation for patients with prolonged dialysis treatment , with improved survival and no deterioration in transplant outcomes. Unlisted patients with long-dialysis vintage should be prioritized for transplant evaluation.

Abstract# 834

Transplant Center Provisional Yes Practices for Deceased Donor Kidneys

A. M. Placona[1], C. Martinez[1], H. McGehee[1], C. Van De Walker[2], J. Rosendale[1], *[1]United Network for Organ Sharing, Richmond, VA, [2]Pacific Northwest Transplant Bank, Portland, OR*

Purpose: Improving organ allocation efficiency has been a focus of the OPTN. While the use of provisional yes (PY) by transplant centers has received recent attention, little is known about these usage and variability of these practices. Our objective was to describe transplant center PY practices at the transplant center and donor level. What is the variability between centers in terms of rate of PY usage? What is the variability in terms of acceptance rates given PY between transplant centers?

Methods: We collected kidney PTR data from 2015 to 2019 retaining all match runs with at least one kidney accepted. We applied logic to remove offers associated with multi-listed candidates, bypassed offers, and offers beyond the final acceptance. Only the first donor recipient pair was retained. We calculated the number of donors offered to each center, how often each center put in a PY for at least one of their candidates for an offered donor, and how often a transplant center accepted a donor organ given a PY was put in for a given donor.

Results: The median PY frequency for transplant centers was 40.22% [IQR: 28.90% to 49.53%]. Demonstrated in figure 1, final acceptance given provisional exhibited variability; the median transplant center acceptance rate given a PY, for at least one of their candidates for a given donor, was 20.09% [IQR: 14.42% to 27.86%]. There were centers with an acceptance rate less than 10% and greater than 40%. While large centers tended to be within the IQR, larger centers are not necessarily associated with lower acceptance rates given a PY. That said figure 2 illustrates a weak relation between the number of donors a provisional yes was inputted and provisional yes rate.

Conclusions: The variability in PY to acceptance rate requires further introspection. While PY rates do not necessarily indicate a metaphorical “rubber stamp”, the variability in acceptance rates combined with some low acceptance rates could indicate room for improvement. Understanding drivers of PY variation, i.e. time of day, missing information, and offer decision making practices, could enable work groups examining this phenomena to develop better solutions to increase system efficiency.

Abstract# 835

Changes to Allocation of En Bloc Deceased Donor Kidneys to Low Epts Patients

A. Robinson[1], M. Pavlakis[2], V. Casingal[3], *[1]United Network for Organ Sharing, Richmond, VA, [2]Beth Israel Deaconess Medical Center, Boston, MA, [3]Carolinas Medical Center, Charlotte, NC*

Purpose: The OPTN implemented a policy on September 5, 2019 standardizing en bloc deceased donor kidney allocation in order to efficiently place and utilize kidneys from small donors. Kidneys recovered from donors weighing less than 18 kilograms are required to be offered en bloc. En bloc match runs follow the same algorithm used for KDPI 0-20% kidneys, as they have been shown to have comparable outcomes. Pediatric and low EPTS candidates were expected to have increased access to en bloc transplants as a result of this change.
Methods: We queried the OPTN database for en bloc deceased donor kidney transplants performed between September 5, 2018 and August 4, 2020. Counts and percent of transplants were compared by EPTS pre- versus post-policy implementation.
Results: There were 210 en bloc deceased donor kidney transplants in the year prior to policy implementation, and 166 in the eleven months following implementation. The proportion of en bloc transplants to EPTS 0-20% recipients more than doubled from 29.5% pre-policy to 75.5% post-policy (**Figure 1**). The proportion of pediatric recipients of en bloc transplants also increased from 0.5% to 1.2%, though this reflected a change of one transplant.
Conclusions: In addition to standardizing en bloc kidney allocation nationally, this policy change directed kidneys with good expected outcomes to patients expected to maximize the longevity of the organ. The OPTN Kidney Committee will continue to monitor its impact.

Abstract# 836

Patient and Physician Perspectives on Kdpi>85 Consent and Kidney Acceptance Decision Making

K. J. Schantz[1], E. Gordon[1], U. Lee[1], M. Rocha[1], J. Friedewald[1], D. Ladner[1], Y. Becker[2], D. Kaufman[3], R. Formica[4], P. Reese[5], M. Barah[1], M. Walker[1], D. Viveros[6], O. Mehrotra[6], S. Mehrotra[1], *[1]Northwestern University, Evanston, IL, [2]University of Chicago, Chicago, IL, [3]University of Wisconsin, Madison, WI, [4]Yale University, New Haven, CT, [5]University of Pennsylvania, Philadelphia, PA, [6]University of Illinois Chicago, Chicago, IL*

Purpose: This study explores patient and physician perspectives on patients' understandings of kidney quality and patients' decision making with regards to consenting for and accepting KDPI>85 kidney offers.
Methods: In-depth,, semi-structured interviews were conducted with transplant candidates (15), transplant recipients (16), transplant surgeons (9) and transplant nephrologists (6). Patients were recruited through the American Association of Kidney Patients (AAKP) and the Northwestern Comprehensive Transplant Center. Physicians were recruited from OPTN committees and a list of transplant center medical directors. Patient interviews focused on education received at their transplant center, understandings of kidney quality and KDPI, and informed consent and kidney acceptance decision making. Physician interviews focused on how they educate patients about kidney quality and which patients they encourage to consent for KDPI>85 kidneys offers. Study team members identified emergent patters within the data, and generated themes following these patterns.
Results: Five themes emerged from the interviews. First, patients reported knowledge gaps and misperceptions about KDPI. Second, patients and physicians indicated limits to shared decision making with regards to KDPI>85 consent. Third, patients considered experiences on dialysis, health status and age in their KDPI>85 consent and acceptance decisions, while physicians reported significant variation in terms of which patients they encourage to consent for KDPI>85 offers. Fourth, patients frequently expressed concerns about infectious disease, although physicians consistently reported encouraging patients to accept PHS increased risk offers. Finally, patients underestimated the survival benefit of transplantation over dialysis, and physicians suggested that patients may misunderstand the relative risks when making consent and acceptance decisions.
Conclusions: Patient consent and acceptance decisions are influenced by the education they receive and their understandings of the tradeoff between accepting a lower quality kidney or remaining on the waiting list. Patients express willingness to accept lower quality kidneys if they offer a benefit in terms of survival and/or quality of life, but they do not always have a good understanding of options such as KDPI>85 consent. More comprehensive education is needed to ensure patients have the resources to make informed consent and acceptance decisions.

Abstract# LB 73

Trends and Outcomes Analysis of U.S. Transplant Centers Performing High Volumes of Hard to Place Kidneys

D. Bahl[1], A. Mahajan[2], H. Aramada[3], Y. Qazi[3], *[1]St. George's University, St. George's, Grenada, [2]University College Cork School of Medicine, County Cork, Cork City, Ireland, [3]Keck Hospital of USC, Los Angeles, CA*

Purpose: Despite a growing number of patients awaiting a kidney transplant, discard rate remains significantly high. The UNOS SRTR data now provides information on all centers about **Hard-to-Place Kidneys (HTPK),** which by definition are allografts allocated and transplanted after initial 100 offers. Our study is an outcomes analysis study of centers that perform high volumes of HTPK, as well as provides a trends analysis for centers that were deemed as high volume in the previous data cycle.

Methods: Scientific Registry of Transplant Recipients (SRTR) data for all active US kidney transplant center's was analyzed to identify centers likely to accept HTPK. Of these programs, High Volume HTPK centers were defined as ones that performed more than a 30 such transplants(tx)/year and their patient and graft survivals were noted. The time period for number of Tx performed was 1/1/19 to 12/31/19 and outcomes analysis from 1/1/17 to 12/31/19. This data was compared to the previous two cycles of data, from 1/1/18 to 12/31/18 and 1/1/17 to 12/31/17.

Results: A total of 2194 HTPK were transplanted in this time period. Only 21/221 (9.5 %) of all U.S. Tx centers performed high volume HTPK centers but accounted for 1290/2194 (58.7%) of such Tx. 8/21(38.1%) had outcomes as expected , 2/21 (9.5%) had below expected outcomes and 11/21 (52.4%) had outcomes above expected. When analyzing HTPK center locations by UNOS regions, Region 9 and 5 each had 6 centers; 6/21 (28.5% each), Region 11: 3/21 (14.2%), Region 2: 2/21 (9.5%), while Regions 3,4,7, and 8 each had 1 center; 1/21 (4.7% each). 49% of HTPK centers were located in AZ, CA, and NY. Region 9 and 5 continue to transplant the highest number of HTPK's, along with region 3, transplanting more than 68.2% of all HTPK. Compared to the last data cycle, an upward trend with outcomes data was observed, with a more than 20% increase in acceptable or above expected outcomes, in addition to overall increase in volume transplanting HTPK's, with a 14% increase.

Conclusions: Our study demonstrates that only 9.5% of all U.S Tx centers are high volume utilizers of HTPK. Our study locates over 68% of such centers in 4 states: Arizona, California, Florida, and New York. 90% of the HTPK centers had acceptable outcomes or better and best practice at these centers are being captured by our ongoing study. Analyzing these centers practices is imperative to understand how to better allocate kidneys with expected outcomes or better. As new organ allocation policies are formulated, center preferences need to be captured in more granularity to identify centers likely to accept a HTPK. Our study suggests when new allocation policies are formulated, algorithms be considered specifically for organs likely to be classified as HTPK and center experience be factored. Expedited offers to such centers would increase the utilization and reduce discard.

Abstract# LB 74

Is Equitable Access to Transplantation Possible in the Era of HLA Epitope Compatibility?

S. Parto[1], J. Lamsatfi[2], B. Liu[2], A. Bourdiec[2], B. Foster[2], K. Oualkacha[2], F. Claas[3], P. Keown[4], R. Sapir-Pichhadze[5], *[1]Medicine, McGill University, Montreal, QC, Canada, [2]McGill University, Montreal, QC, Canada, [3]Leiden University Medical Centre, Albinusdreef, Netherlands, [4]University of British Columbia, Vancouver, BC, Canada, [5]Medicine, McGill University Health Centre, Montreal, QC, Canada*

Purpose: We applied the calculated Panel of Incompatible Epitopes (cPIE), an algorithm informing on the likelihood of identifying blood group and eplet-compatible donors, to study how self-reported ancestry affects access to transplantation.

Methods: Candidates were identified from an incident cohort of 6169 0% PRA patients in the Scientific Registry of Transplant Recipients first activated on the kidney waiting list Jan 1, 2011 to Dec 31, 2011. Patients listed at multiple centres were excluded. For cPIE estimation, the donor pool was composed of 4608 consecutive deceased donors who presented Jan 1, 2010 to Dec 31, 2010. Imputed allele-level genotypes for HLA A, B, C, DRB1, and DQB1 were transformed to epitypes. The likelihood of finding blood group matched and eplet compatible donors by candidates' self-reported ancestry was estimated for various eplet compatibility thresholds (by HLA class, antibody-verified (AbVer), and subsets of 55 and 15 eplet mismatches (EMM) increasingly important for predicting death censored graft failure). For each threshold, donors were deemed compatible, if all their eplets were included in the candidates' epitypes (0 EMM). Distribution of cPIE when accepting residual ≤2 and ≤5 EMM were also assessed.

Results: Likelihood of identifying compatible donors (Median and Interquartile Range (IQR)) for Asian (N=300), Black (N=1194), Native American (N=52), Pacific Islander (N=31), White (N=4592) and Latino (N=1025 some overlap with prior groups) candidates was greater for subsets of higher risk eplets vs. class II AbVer, all AbVer, and complete epitypes (Figure 1). There was heterogeneity in the likelihood of identifying compatible donors at the individual level within each self-reported ancestry group, with Black candidates less likely to match. For each eplet compatibility strategy, matching was more likely for candidates accepting donors with residual ≤2 and ≤5 EMM. We found similar patterns in candidates activated in 2012 considering the 2011 donor pool.

Conclusions: Verification of allele-level HLA genotype is required for candidates of any ancestry to inform on access to eplet compatible transplants. For harder to match candidates, preferences must be established on the trade-off between immune risk and gaining access to transplantation when considering donors with residual EMM .

Kidney Deceased Donor Selection

Abstract# 837

Days of Delayed Graft Function and Its Impact on Graft Outcomes in Deceased Donor Kidney Transplant

P. Budhiraja[1], R. J. Butterfield[2], S. S. Misra[1], K. S. Reddy[3], L. Kodali[1], H. A. Khamash[1], S. Nair[1], G. K. Mour[1], H. A. Chakkera[1], C. C. Jadlowiec[3], H. Janna[1], R. L. Heilman[1], *[1]Department of Medicine, Mayo Clinic Arizona, Phoenix, AZ, [2]Department of Statistics, Mayo Clinic Arizona, Phoenix, AZ, [3]Department of Surgery, Mayo Clinic Arizona, Phoenix, AZ*

Purpose: There has been controversy regarding impact of delayed graft function (DGF) on risk of acute rejection and graft survival. This is likely due to DGF being reported as a dichotomous outcome and does not account for the difference in days of DGF.

Methods: We studied predictors and impact of DGF days on transplant outcomes in subjects who received deceased donor kidney transplant from 2003 to 2019 at our center. We have high rates of DGF as we accept high KDPI, long CIT and donor kidneys with AKI. We excluded cases with primary non function unrelated to DGF and preemptive transplant. Recipient and donor characteristics were compared by DGF status using *Kruskal-Wallis* test for continuous variables and χ^2 for categorical variables. Risk factors for DGF status and increased DGF days were assessed. We compared the chronic changes on the protocol biopsy performed from preimplantation to 4 month and 12 month. We used unadjusted and adjusted Cox Proportional Hazard model to assess graft survival, censoring for death events.

Results: There were 701 subjects without DGF and 1021 recipients who had DGF. Factors that were significantly associated with higher DGF days on multivariable analysis included dialysis vintage, DCD status, CIT, donor age and donor oliguria. There was association of acute rejection with presence of DGF with but not with DGF days. Risk for BKV infection and graft survival was not associated with DGF days on multivariate cox -proportional hazard model. At 12-month biopsy, each additional day of DGF conferred 4.5% increased odds of chronic interstitial fibrosis progression and 3.7% increased odds of chronic tubular atrophy progression from baseline.

Conclusions: This is first large cohort study to report the impact delayed graft function days on progression of fibrosis, rejection and graft survival. There is no higher risk of rejection, infection or graft survival. However, we did find association of DGF days with progression of fibrosis.

Abstract# 838

Long-Term Outcomes in Older Kidney Transplant Recipients from Older Donors

E. Cuadrado-Payán, E. Montagud-Marrahi, J. Casals-Urquiza, J. del Risco-Zevallos, D. Cucchiari, P. Ventura-Aguiar, I. Revuelta, G. Piñeiro, N. Esforzado, F. Cofan, J. Ugalde, J. Campistol, F. Oppenheimer, J. Torregrosa, F. Diekmann, *Nephrology and Kidney Transplantation, Hospital Clínic de Barcelona, Barcelona, Spain*

Purpose: The age of patients referred for kidney transplantation has increased progressively. However, the precise influence of age on hard outcomes after transplantation is controversial
Methods: Single-centre, longitudinal retrospective study in which graft and recipient survival in a cohort of ≥75 years old kidney recipients were compared with a contemporary younger cohort aged 60-65 years.
Results: We included 149 recipients between 60-65 and 60 patients of ≥75 years old. No differences in baseline characteristics were observed except for the prevalence of diabetes mellitus (62 patients versus 9 patients respectively, p < 0.0001). One- and five-year recipient survival was lower in the older group (91% and 76% for the older and 96% and 87% for the younger group, P =0.01). In the multivariate analysis, recipient age was not associated with an increased risk of death. Donor after Circulatory Death (DCD), recipient Ischemic Heart Disease and Delayed Graft Function (DGF) were associated with an increased risk of death. One- and five-year death-censored graft survival did not significantly differ between both groups (90% and 85% for the older and 98% and 88% for the younger group, respectively, *P* =0.08). In the multivariate analysis age was no associated with graft loss (HR 2.84, 95%CI [0.77-8.12], *P* =0.09), although DGF was (HR 4.46, 95%CI [1.63-12.21], *P* =0.004). DCD donor (OR 2.88, 95%CI [1.07-7.78], *P* =0.03) and Deceased Donor Kidney Transplantation (OR 2.51, 95%CI [1.26-4.99], *P* =0.009) were risk factors for DGF.
Conclusions: Recipient age should not be considered itself as an absolute contraindication for kidney transplant. With a judicious selection of the recipient and the donor, kidney transplantation can be safely performed in elderly patients.

Abstract# 839

Outcomes in Highly Sensitized Kidney Transplant Recipients Receiving DCD Organs

A. Diamond[1], L. Rodrigues[2], A. Di Carlo[3], S. Karhadkar[3], *[1]Pharmacy, Temple University Hospital, Philadelphia, PA, [2]Temple University, Philadelphia, PA, [3]Surgery, Temple University Hospital, Philadelphia, PA*

Purpose: Highly sensitized (HS) patients experience longer wait times for kidney transplantation despite prioritization by the Kidney Allocation System. Kidney transplants performed from donors defined as donation after circulatory death (DCD)

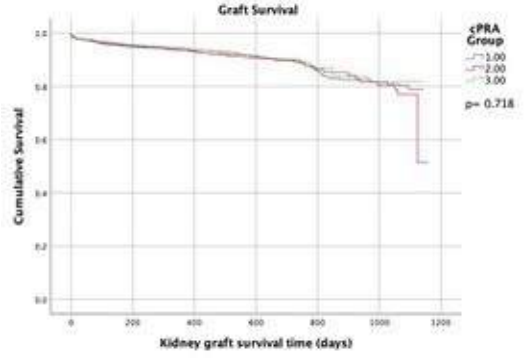
have been shown to decrease wait times for most patient populations. However, concern for increased rejection during delayed graft function (DGF) causes hesitancy in using DCD kidneys in HS patients. In this study, we evaluate the outcomes of HS kidney transplant (KT) recipients who received a DCD kidney.

Methods: KT recipients who received DCD organs from 2015-2018 were studied using the United Network for Organ Sharing database. Patients were divided into three groups for analysis; calculated panel-reactive antibody (cPRA) 0% (Group 1), 1-89% (Group 2), and 90-100% (Group 3). Data analysis was performed with the SPSS software. Survival analysis was performed using a Cox regression and Kaplan-Meier model.

Results: 7,854 KT recipients received DCD kidneys. Patients were divided into three groups: cPRA 0% (n= 4,598), cPRA 1-89% (n= 2,233), and cPRA 90-100% (n= 1,023). There was no significant difference in baseline characteristics (see Table 1). The mean KDPI in Group 3 was lower compared to other groups (51% vs. 50% vs. 44%; p<0.001). Rabbit antithymocyte globulin induction was used for most patients (58% vs. 66% vs. 75%). The incidence of DGF was similar between groups (41% vs. 42%. vs. 42%; p= 0.45). A higher number of patients in Group 3 were treated for rejection within 12 months (4.2% vs. 4.1% vs. 6.1%; p=0.003). No differences in graft failure (7.1% vs. 7.1 % vs. 6.7%; p=0.905) and patient survival (95% vs. 95% vs. 96%; p=0.449) were noted. A Cox regression model identified KDPI as a significant factor, independent of cPRA, impacting graft survival (OR 3.76; 95% CI: 2.61-5.41).

Table 1

	cPRA 0% N= 4,598	cPRA 1-89% N= 2,233	cPRA 90-100% N =1,023
Recipient age (years), mean ± SD	54.1 ± 13.1	53.1 ± 13	49.5 ± 13
Donor age (years), mean ± SD	38.5 ± 14.6	37.8 ± 14.4	35.1 ± 13.1
Recipient gender (male), n (%)	3072 (66.8)	1490 (66.7)	696 (68)
Recipient ethnicity, n (%) White; Black	1891 (41.1); 1390 (30.2)	855 (38.3); 735 (32.9)	443 (43.3); 299 (29.2)
Donor ethnicity, n (%) White; Black	3687 (80.2); 347 (7.5)	1777 (79.6); 187 (8.4)	758 (74.1); 78 (7.6)
Days on dialysis prior to transplant, mean ± SD	1907.3 ± 1110.3	1941.6 ± 1107	1798.3 ± 1455.5
EPTS, mean ± SD	53.14 ± 29.77	51.02 ± 29.39	45.89 ± 28.52



Conclusions: DCD kidney transplantation provides HS patients with comparable long term graft survival with an acceptable incidence of treated rejection within 12 months. Notably, KDPI had a larger influence on graft survival than the recipient's cPRA. This study supports an increased use of DCD kidneys in HS patients.

Abstract# 840

Findings from the BARETO Study: A New, Composite Renal Vascular Plaque Score is Highly Associated with Kidney Graft Survival

J. Foutz[1], D. Stewart[1], L. Kamal[2], H. McGehee[1], P. Saravanane[2], S. Yu[2], R. Yousfi[2], G. Gupta[2], *[1]United Network for Organ Sharing, Richmond, VA, [2]Virginia Commonwealth University School of Medicine, Richmond, VA*

Purpose: Whether anatomic findings such as aortic and arterial renal plaque affect kidney graft outcomes is not well defined. Other than anatomical damage, it is unclear whether anatomy features should influence organ offer acceptance decisions. As part of a broader study on Biopsy, Anatomy, and Resistance Effects on Transplant Outcomes (BARETO), we aim to characterize the association between renal plaque on long-term kidney graft survival to help inform decision making.

Methods: Data were manually entered for a preliminary cohort of 4,475 ECD donor single kidney transplants from 2008-2011. Degree of aortic (hard=2, soft=1, none=0) and arterial (hard=2, soft=1, none=0) renal plaque were added to create a new, composite plaque score (0-4). Kaplan-Meier graft survival analysis out to 10 years was stratified by composite plaque score. Causal inference was performed using doubly robust regression (DRR) to adjust for 17 potential confounders.

Results: Kaplan-Meier survival analysis revealed a significant (p=0.003) association between plaque score and graft survival probability, with a plaque score of 0 associated with higher graft survival probability and a plaque score of 4 associated with lower graft survival probability (Figure 1). In the unadjusted model, a plaque score of 4 (vs. 0) was associated with significant risk of graft failure (HR: 1.29, 95% confidence interval (CI): 1.11-1.50); this effect attenuated somewhat (HR 1.15, CI: 0.98-1.36) with DRR (Fig 2). A dose-response relationship appears to be emerging based on initial data.

Conclusions: This new, composite renal plaque score is associated with long-term graft survival outcomes. Specifically, the presence of hard aortic and/or arterial plaque is associated with worse long-term graft survival. Findings from our ongoing study can help inform transplant decision making, including by their incorporation into multivariable graft survival models that summarize organ quality.

Abstract# 841

Not Quite Right: The Irony of Longer Cold Times for Higher KDPI Kidneys

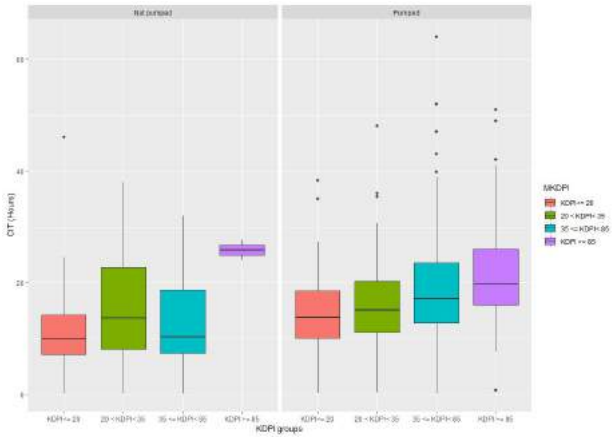
H. Ghali[1], D. Won[1], S. Yoon[1], A. Friedman[2], *[1]Systems Science and Industrial Engineering, SUNY Binghamton, Binghamton, NY, [2]LiveOnNY, New York, NY*

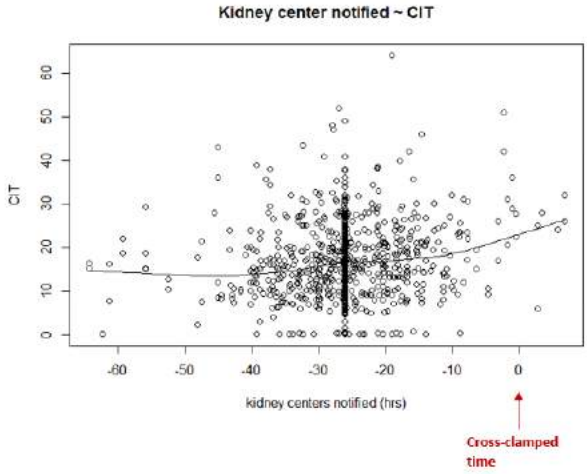
Purpose: To identify tactics for reduction of the kidney discard rate, we analyzed measurable, operational factors contributing to the key outcome of transplantation (TXP) or discard.

Methods: A retrospective review of deceased donor kidneys recovered and allocated (1/1/17 - 12/31/18) from a single, large organ procurement organization (OPO) was undertaken using internal records and UNOS data. Factors analyzed for locally transplanted (within the OPO's donor service area) organs included KDPI, cold ischemic time (CIT), hypothermic pulsatile perfusion pump use, and formal TXP center notification time (relative to cross-clamp).

Results: A total of 519 donors from whom 1028 kidneys were recovered, with 18.4% DCD, a median KDPI of 70, and an overall discard rate of 17% were included. Higher KDPI was significantly associated with the likelihood of being pumped (see figure). For kidneys transplanted locally and pumped (N=772), CIT and KDPI correlated significantly; the higher the KDPI, the longer the CIT (see figure). Regression analysis of 803 locally transplanted kidneys (pumped and non pumped) with available CIT data and 4 key time points (HLA sent, crossmatch sent, kidney center notified, serologies sent) identified only the time of center notification as a significant factor (p=0.03) inversely linked to CIT.

Conclusions: The use of hypothermic pulsatile perfusion pumping for marginal (high KDPI) kidneys was observed and is evidence-based. The observation that CIT was significantly prolonged for these marginal, pumped organs is, however, contrary to common sense or ideal practice. This important observation should be analyzed carefully to identify opportunities to improve allocation efficiency and improve the treatment of these organs. We have initially identified the relevance of early center notification as such a factor.





Percentage of pumped kidneys by KDPI group		
KDPI Groups	**N**	**% Pumped**
KDPI<=20	115	47
20<KDPI<35	119	71
35<=KDPI<85	439	85
KDPI>=85	99	98

Abstract# 842

The Extremes of KDPI: Even KDPI 95%+ Kidneys Can Be Used Successfully

A. Gilbert, J. Verbesey, B. Thomas, J. Moore, M. Cooper, *Medstar Georgetown Transplant Institute, Washington, DC*

Purpose: While the use of kidneys with KDPIs greater than 85% has become common, there is still reluctance among centers to use the very highest KDPI kidneys (95%+) for fear of poor outcomes. In our center's highly competitive region we have routinely used these kidneys and with the upcoming changes in the kidney allocation system, we expect this to increase. We reviewed our experience with these high KDPI kidneys to see if their outcomes warrant continued use.

Methods: This is a single center retrospective study. We reviewed all patients receiving deceased donor kidney (DDK) transplants since KDPI was put into common use in December 2014. We looked at graft survival, death censored graft survival (DCGS), delayed graft function (DGF), extended DGF (greater than 10 days) and primary non-function (PNF) as outcomes measures. We also stratified transplants by the age of the recipient into 2 groups: those 61 years old or greater, and those 60 years old or younger. Data was analyzed using Fishers exact test with a 2-tailed p value.

Results: We had a total of 753 solitary DDKs transplanted at our center. There were 80 kidneys that had a KDPI of 95% or greater. Average follow-up was 25.2 months although the high KDPI group did have overall shorter follow-up (mean 18.7 months, p=0.001). There was no difference between the groups in graft survival (figure 1, p=0.59) or DCGS (91.2% vs 90.2% p=1.0). The high KDPI group had somewhat higher but statistically similar rates of DGF (36.7% vs 30.2% p=0.055). When looking only at extended DGF the differences reached statistical significance (21.3% vs 11.1% p=0.017).

When stratified by recipient age, there were no statistically significant differences in graft survival, DCGS, DGF, or extended DGF either when comparing high KDPI vs low KDPI kidneys in elderly patients, or when comparing high KDPI kidneys in elderly vs younger patients (table 1).

Conclusions: In an increasingly competitive environment, kidneys with KDPIs of 95%+ can provide excellent medium-term results for recipients of all ages similar to those seen with lower KDPI kidneys. These organs represent an increasingly valuable resource which will need to be used aggressively as we adapt to a new kidney allocation system that further encourages competition between centers.

Outcomes of Transplant by KDPI and Recipient Age					
	KDPI 95+, Age >60	**KDPI 95+, Age <60**	**p value**	**KDPI <95, Age >60**	**p value**
Number	39	41		185

Abstract# 843

Effect of Donor Glomerulosclerosis and Interstitial Fibrosis/ Tubular Atrophy (IFTA) on Kidney Graft Survival: A Single Organ Procurement Organization (OPO) Data

P. Homkrailas[1], M. Hussain[1], G. M. Danovitch[1], K. Wheeler[2], S. Bunnapradist[1], *[1]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA, [2]OneLegacy, Los Angeles, CA*

Purpose: The kidneys of deceased donors are often biopsied to evaluate transplant organ quality. A high percentage of GS is a leading cause of kidney discard yet donor GS has failed to predict graft failure and there is limited data supporting the association between IFTA and graft failure. Here we report the effect of donor GS and IFTA on graft survival at a single large OPO.

Methods: OneLegacy OPO data of deceased kidney donors with kidney biopsy results from 2015-2019 were included and merged with graft outcomes from the OPTN/UNOS data.

Results: A total of 1,148 deceased donor kidney transplants (DDKTs) were included. The median followed up time was 2 years (IQR 1-3). There were 71 (6.2%) death-censored graft failure. Donors with 0-5%, 6-10%, 11-15%, 16-20%, and >20% GS had 1-year death-censored graft survival (DCGS) of 97.6%, 96.8%, 92.3%, 94.9% and 96.9%, and 3-years DCGS of 93.3%, 92.3%, 91.0%, 90.4% and 91.5%, respectively. Donors without IFTA, mild IFTA, mild to moderate IFTA, and moderate IFTA had 1-year DCGS of 98.4%, 96.4%, 96.4%, and 96.4%, and 3-years DCGS of 97.6%, 91.3%, 96.4% and 88.4%, respectively. After adjusted for kidney donor profile index, only mild IFTA was associated with an increased risk for graft failure at 3-years (aHR 3.54; 95%CI, 1.23-10.15). Donor kidneys with any degree of GS or IFTA had a higher median serum creatinine at 1-year and 3-years followed up compared to those without GS or IFTA .

Conclusions: Overall donor kidneys with any degree of GS or IFTA have an excellent graft survival. One-year and three years DCGS in kidneys with GS were more than 90%. Kidneys with IFTA had 1-year DCGS more than 95% and 3-years DCGS more than 85%.

Abstract# 844

Comparison of Kidney Transplantation Outcomes Between Donors After Controlled Circulatory Death and Brain Death Donors in Catalonia, Spain

J. Juega[1], M. Pérez-Sáez[2], J. Comas[3], A. Zapatero[4], M. Crespo[2], J. Tort[3], R. Lauzurica[1], J. Pascual[2], *[1]Nephrology, Germans Trias i Pujol Hospital, Badalona, Barcelona, Spain, [2]Nephrology, Hospital del Mar, Barcelona, Spain, [3]Departament de Salut, Organització Catalana de Trasplantaments (OCATT), Barcelona, Spain, [4]Intensive care unit, Hospital del Mar, Barcelona, Spain*

Purpose: The number of kidney transplants (KT) from controlled cardiac death donors (cDCD) has exponentially increased in Spain during the last years. Results from cDCD KT have been reported to be comparable to brain-death donors (DBD) KT in countries with long tradition of retrieving organs from cDCD. No studies have compared KT outcomes between these two types of donors in Spain, being this the main purpose of our study.

Methods: Observational retrospective analysis including 1658 KT from DBD and 645 KT from cDCD, performed from January 2013 to December 2018 in Catalonia, Spain. Data were obtained from the Catalonian Registry of Renal Patients (RMRC) including donors, recipients and process of donation-transplantation. Median follow-up after KT was 26 months. A multivariate analysis was performed to identify risk factors for graft loss.

Results: Both donors and recipients mean ages were significantly higher in the cDCD group compared to DBD group. (62 ± 13 vs. 58 ± 17 for donors, p<0,001; 60 ± 12 vs. 56 ± 15 for recipients, p <0,001). Incidence of delayed graft function (DGF) was higher in cDCD KT group (37.2% vs 21.6%, p<0.001) without differences in primary non-function rates (1.7% vs 0.8%, p=0.13). Renal function at 20 months was slightly better in DBD group (eGFR 52.4 ml/min vs 47.1 ml/min, p=0.001). At 3 years post KT no differences in death-censored graft survival were observed (91.2 vs. 91.3%). However, patient survival at 3 years was worse in cDCD group (85.3 vs. 89.3%). In multivariate analysis, recipient age >75 yr, previous cardiovascular disease and DGF were independent risk factors for patient death (RR 10.4, 2.28 and 1.8 respectively). Regarding graft survival (death censored), Donor Age > 75

(RR 2.76), DGF (RR 1.85) and cPRA>50% (1.57) increased graft loss. The type of donation (cDCD vs DBD) was not an independent risk factor neither for patient survival nor graft loss.

Conclusions: In a contemporary recent cohort, graft survival from both cDCD and DBD donors is comparable. Patient survival was lower in cDCD group independently from type of donation, finding recipient age >75 years, DGF and previous CV disease as risk factors pfor patient death. Risk factors for graft loss were cPRA>50%, donor age > 75 and DGF.

Abstract# 845

Donation After Cardiac Death (DCD) Agonal Phase Physiology is Associated with Post-transplant Kidney Graft Outcomes

A. Kayastha[1], K. C. Eddinger[2], E. M. Sonnenberg[2], N. Mahmud[2], D. E. Schaubel[1], P. L. Abt[2], *[1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [2]Hospital of the University of Pennsylvania, Philadelphia, PA*

Purpose: Kidneys procured from DCD donors play a key role in addressing the kidney shortage in the United States, and donor hemodynamics during obligatory warm ischemia may provide insight into graft quality and outcomes. There have been no large-scale studies evaluating these relationships.

Methods: The UNOS registry was used to identify DCD kidney donors and their corresponding recipients. The dataset included donor and recipient demographic data, follow-up data, and agonal phase donor hemodynamic time-series data. The systolic blood pressure (SBP) and oxygen saturation (SpO_2) time-series were analyzed using various quantitative techniques, including computing slopes and areas under the curve (AUC). Asystolic time, defined as the time from when SBP reached 0 mmHg to cross-clamp, was also modeled. Univariable and multivariable logistic regression were used to analyze associations between calculated hemodynamic measures and delayed graft function (DGF), defined as whether the recipient required dialysis within one week after transplant. Univariable and multivariable Cox regression were used to evaluate analogous associations between hemodynamic measures and 90-day, 1-year, and 3-year graft failure.

Results: Analysis was completed on 1911 DCD kidney donors between 2012 and 2018. The time beyond SBP < 50 mmHg was found to be associated with DGF in a multivariable model (OR = 1.021, p < 0.001). The slope of the SpO_2 curve demonstrated significance in a multivariable model with respect to DGF (OR = 1.030, p < 0.001). Asystolic time was found to be significantly associated with DGF and graft failure in all models (Table 1).

Summary of Asystolic Time Results, by Outcome and Model Type

	Univariable Model	Multivariable Model
DGF	OR = 1.027, p < 0.001	OR = 1.026, p < 0.001
90-day Graft Failure	HR = 1.036, p = 0.001	HR = 1.028, p = 0.019
1-year Graft Failure	HR = 1.026, p = 0.011	HR = 1.022, p = 0.037
3-year Graft Failure	HR = 1.025, p = 0.003	HR = 1.022, p = 0.012

Conclusions: A number of hemodynamic measures are independently associated with DGF and graft failure. Greater asystolic times are associated with worse outcomes. These methods that quantify agonal phase hemodynamics are techniques that help better characterize DCD donor kidney quality and recipient graft outcomes, which may help inform organ selection and expand the donor pool.

Abstract# 846

Impact of Elevated Initial Donor Creatinine on Outcomes After Transplanting Kidney from Deceased Donor with Severe AKI

L. Kodali, K. Reddy, P. Budhiraja, S. Nair, G. Mour, J. Huskey, C. Jadloweic, H. Khamash, H. Chakkera, R. Heilman, *Medicine, Mayo Clinic, Arizona, Phoenix, AZ*

Purpose: Several studies have shown good outcomes with transplanting kidneys from deceased donors with AKI; however, the impact of having elevated initial donor creatinine has not been studied. Transplant centers are reluctant to use kidneys from Donors with an elevated initial serum creatinine due to concern for poor outcomes. Our hypothesis is that outcomes after transplanting kidneys from carefully selected donors with severe AKI and elevated initial creatinine are non inferior. We aim to look at the graft and patient outcomes of AKIN 3 donor kidneys with initial or admit creatinine ≥2.0 when compared to AKIN 3 donors with an admit creatinine < 2.0.

Methods: We included all deceased donor kidney transplants done at our center from 2008 to 2019. We excluded combined simultaneous extra renal organ transplant recipients. The donor AKI was classified using the AKIN staging criteria using serum creatinine criteria using data from DonorNet. We selected all recipients of AKIN3 donor kidneys and we divided the study group based on donor initial creatinine ≥2. Preimplantation biopsies were reviewed by our surgical pathologists, and kidneys with cortical necrosis >10% or mild chronic changes were discarded. Protocol biopsies were performed at 4 months and 1 year.

Results: We identified 683 (34.5%) donors with AKIN 3, out of which 156 (22.8%) were identified to have initial creatinine ≥2. Recipient age, gender, prevalence of diabetes and dialysis were similar in both groups. There were younger donors in the cohort with initial creatinine ≥2 (30.9 vs 37.4 p <0.001), which was also reflected in the KDPI (35.0 vs 52.5 p=<0.001). More female donors were present in the group with creatinine <2 (38.0 vs 16 p=<0.001). There was no statistical significance in DCD donors in the 2 groups. DGF rates were higher in the group with initial Cr ≥2 (85.3 vs 77.6%, p=0.03). CIT was similar in both the groups. There was no difference in the death censored graft survival, acute rejection and primary non-function between the 2 groups at 1 year. Estimated GFR was higher in donors with initial Cr ≥ 2 at both 4 months (62.4 vs 54.8 ml/min/1.73 m^2, p=0.0001) and 1 year (64.6 vs 58.6ml/min/1.73m^2 p=0.0086). There were less chronic changes noted on the 1 year protocol biopsy in the group with Cr ≥2.

Conclusions: With careful selection, AKIN3 donors with initial Cr≥2 have similar 1 year graft outcomes when compared to AKIN3 donors with initial creatinine <2.0. The favorable GFR and biopsy findings at 1 year are probably related to donor factors.

Abstract# 847

Hypoperfusion Warm Ischaemia Time in Renal Transplants from Donors After Circulatory Death

I. D. Kostakis[1], T. Kassimatis[1], C. Flach[2], N. Karydis[1], N. Kessaris[1], I. Loukopoulos[1], *[1]Department of Transplantation, Guy's Hospital, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [2]School of Population Health and Environmental Studies, King's College London, London, United Kingdom*

Purpose: Donor hypoperfusion before asystole in renal transplants from donors after circulatory death (DCD) has been considered responsible for worse outcomes than those from donors after brain death (DBD). We assessed how the duration of hypoperfusion phase [hypoperfusion warm ischaemia time (HWIT)] affects the outcomes of DCD renal transplants.

Methods: We included 10309 adult renal transplants (7128 DBD, 3181 DCD) (01/01/2010-31/12/2016) from the UK Transplant Registry. We divided DCD renal transplants in groups according to HWIT. We compared delayed graft function (DGF) rates, primary non-function (PNF) rates and graft survival among them using DBD renal transplants as reference group.
